## GLASGOW

**GLASGOW**, the chief commercial and manufacturing city of Scotland, in Lanarkshire, on the river Clyde, 21 m. from its mouth, and 41 m. W. S. W. of Edinburgh; lat.  $55^{\circ} 51' 32''$  N., lon.  $4^{\circ} 17' 54''$  W.; pop. in 1660, 12,000; in 1765, 23,046; in 1801, 83,769; in 1851, 347,001; in 1861, 395,503; in 1871, of the parliamentary burgh, 477,144, of the whole town, 547,538. The city is about 3 m. long, and lies on both sides

of the river, here about 500 ft. wide, which is crossed by two suspension and three stone bridges, below which are several ferries. The site is mostly level, but in the N. and N. W. parts are considerable elevations. The original burgh, which took its rise from the cathedral and the university, is on the N. bank; but the various suburbs are now so closely connected that they can hardly be considered otherwise than

Albert Bridge, Glasgow.

as portions of one compact city. The principal streets are parallel with the river, two of the broadest bordering it on either side. There are three public parks: the Green, of 140 acres, on the N. bank of the Clyde, near the E. end of the city; Kelvingrove, of 40 acres, at the W. end; and Queen's park, of 100 acres, on elevated ground at the south. These parks are

all handsomely laid out and ornamented. The streets mostly cross at right angles, are well paved, lighted, and drained, and are adorned with several fine statues. Many of the houses are of white freestone, constructed in flats. There are two theatres, two museums, two public libraries (of 30,000 and 15,000 volumes), asylums for the blind, insane, aged, and deaf

and dumb, a university, and 175 churches and chapels. The last named are divided as follows: Free church, 43; Established church, 40; United Presbyterian, 37; Roman Catholic, 12; Independent, 9; Baptist, 7; Episcopal, 5; Reformed Presbyterian, 4; other denominations, 18. A bishopric was erected in Glasgow about 1115; in 1488 it was made an archbishopric. At present it is the seat of a bishop of the Scotch Episcopal church and of a Roman Catholic vicar apostolic. Five daily and 15 weekly newspapers are published. There is a botanic garden of 40 acres in the N. W. part of the city, which is open to the public in summer. The cathedral, said to be the finest Gothic building in Scotland, overlooks the city from the northeast. It was built by David I. about 1138, but was burned in 1192; the present edifice was immediately begun, and was consecrated in 1197, but was not finished until the present century. Its most celebrated features are the crypt and the profusion of brilliant stained glass. The university was chartered in 1443 by James II., but it had only a feeble existence until 1560, when Queen Mary bestowed upon it half of the confiscated church property in the city; this endowment has been greatly increased by additional grants from the corporation and the crown. It has a library of 105,000 volumes, founded in 1473, an observatory, and numerous cabinets and collections. The grounds include 22 acres, and the new buildings, finished in 1870, cost £370,000. The number of matriculated students averages 1,200. The university confers degrees in arts, law, medicine, and divinity. The principal public buildings are the royal exchange, the town hall, and Hutcheson's hospital. The city is supplied with water from Loch Katrine, by an aqueduct 26 m. long.—Glasgow was erected into a burgh about 1190, with the privilege of an annual fair. In 1556 it ranked eleventh among the towns of Scotland. It is now the fourth exporting city of Great Britain, and the second in wealth and population. Its immense growth, mainly within the present century, is due to its situation in the midst of a rich coal and iron district, and its seaport facilities. Large sums have been spent in clearing and deepening the channel of the Clyde, including the removal of several islands, and it is now navigable for vessels of 2,000 tons. The quays are 16,680 ft. in extent. In the 18th century Glasgow was the centre of the tobacco trade of Great Britain, and its merchants also dealt largely in the sugar and other products of the West Indies. Later it entered extensively into brewing, dyeing, and calico printing, and finally into ship building (especially of iron ships), iron casting, and machine making, and the preparation of chemicals. The St. Rollox chemical works, the largest in the world, N. of the cathedral, cover 16 acres, employ more than 1,000 men, and have a chimney 450 ft. high. A still taller chimney (460 ft.) is that of the artificial manure works. In 1871 the number

of spindles was 2,000,000, consuming annually 125,000 bales of cotton, and supplying 27,000 power looms. There are large glass works and paper mills, and the turkey-red dyes produced here are famous. The value of exports in 1871 was £10,049,987, of which £2,223,221 were to the United States; the value of imports was £6,577,575, of which £2,894,273 were from the United States. Glasgow is governed by a lord provost, 8 bailies, and 39 councillors, with the dean of guild from the merchants' and the deacon convener from the trades' house, and returns three members to the house of commons.—The Romans had a station on the Clyde in the locality of the city, and Antoninus's wall commenced a few miles W. of it. Tradition assigns the foundation of Glasgow to St. Kentigern, whom it makes its first bishop, about 560. In 1300 a battle between the Scots under Wallace and the English under Percy was fought in the High street, when Percy was defeated and slain. In 1350, '80, and '81, Glasgow was visited by the plague. About 1542 the regent Arran besieged the earl of Lennox in the bishop's castle, obtained it on promise of terms, and put the garrison to the sword. The same leaders subsequently fought a battle at the Butts in the E. part of the city, when the regent gained the victory and plundered it. In 1560 reformed superintendents superseded Catholic bishops. In 1638 the famous assembly of the Presbyterian church was held here, when episcopacy was abjured. For several years thereafter the city was a prey to both parties in the civil wars. Fire, plague, plunder, and famine desolated the place. On June 4, 1690, a charter of William and Mary conferred on the townsmen the right of electing their own magistrates. Glasgow was strongly dissatisfied with the union of Scotland and England, but in 1715 and again in 1745 sided with the house of Hanover and raised a force against the Stuarts, for which the pretender's army on the retreat from Derby levied contributions. On the breaking out of the American revolutionary war, Glasgow raised a regiment of 1,000 men, and fitted out 14 privateers. In 1820 the public peace was disturbed by radical political riots, and in 1848 by the chartists.

**GLASS** (Sax. *glas*), in chemistry, any product of fusion having the peculiar lustre known as vitreous, hard and brittle, whether transparent or not; in common use, the transparent product derived from the fusion of silica with an alkali to which lime or a metallic oxide is added. No material invented by man is to be compared with glass in the service it has rendered. To its aid, applied in a thousand different forms, the sciences, particularly chemistry and astronomy, are essentially indebted for their advancement; and its uses in common life render it no less important to the daily wants of mankind. The purity of its material causes the presence of foreign substances to be instantly detected, and it is consequently the most cleanly substance, and especially suited

for vessels for holding and keeping liquids. It resists the action of nearly all the powerful chemical reagents; and but for this substance many of them would never have been known, nor could they now be made and kept.—Nothing definite is known concerning the discovery of the art of glass making or the early history of its manufacture. The statement made by Pliny that some Phœnician mariners having landed on the banks of a small river in Palestine, “and finding no stones to rest their pots on, they placed under them some masses of *nitrum* [soda, as is supposed], which, being fused by the heat with the sand of the river, produced a liquid and transparent stream,” is not generally accepted as showing the origin of glass. A stronger heat than could be obtained from an open fire would be required to effect this result. Nor is much more credit to be attached to his accounts respecting the production of a glass of malleable character, which when thrown upon the ground was merely indented, and could be restored to shape with a hammer, as if it were brass. Some metallic salts, as chloride of silver, possess ductility at the same time with a glossy appearance, and of one of them the articles referred to may perhaps have been made; but all modern experience is opposed to the possibility of a vitrified body being malleable. It has been established with certainty that the art was practised among the Egyptians at a very early period. Paintings on a tomb at Beni Hassan, supposed to date from the reign of Osortasen I., about 3,000 B. C., represent Theban glass blowers at work with blowpipes very similar to those used at the present day. A necklace bead of material similar to the modern crown glass was found at Thebes, bearing the name of the queen of Thothmes III., who reigned about 1500 B. C., inscribed in hieroglyphics. In the British museum there is an interesting ancient Egyptian specimen in the form of a small bottle of opaque light-blue glass, on which

but also for mosaic work, the figures of deities and sacred emblems, and even for coffins, in all of which they attained excellent workmanship and surprising brilliancy of color. The glass works of Alexandria, in operation in the time of Strabo and Pliny, were famous among

FIG. 2.—Blue Glass Bottle with Name of Thothmes III.

FIG. 3.—Green Glass Vase with Name of Sargon.

the ancients. According to Theophrastus, the processes of cutting or grinding, of gilding and coloring, were in use 370 years B. C. Articles of exquisite workmanship were produced, but of great cost, and known only as luxuries. Vases and cups, some enamelled and beautifully cut and wrought with raised figures, and some remarkable for the brilliancy of their colors, were furnished to the Romans. From the Egyptians the Phœnicians are supposed to have received the art, which flourished at a very early period at Sidon and Tyre. In the ruins of Nineveh glass lenses, vases, bottles, &c., have been found; but there is no indication of the use of glass for windows. A small vase of transparent green glass, on which are engraved in outline a lion and the name and titles of the Assyrian monarch Sargon, 719 B. C., is preserved in the British museum, and is regarded as the earliest dated specimen of transparent glass. It was found in the palace of Nimrud in Nineveh. That the manufacture of glass was extensively practised by the ancient Greeks, and that they had acquired great skill in the art, are shown by the remarkable collection of specimens taken by Cesnola from the tombs at Dali on the island of Cyprus in 1866–70, and deposited in the metropolitan museum of art, New York, in 1872. This collection of Greek glass, the most extensive known, comprises 1,700 articles, not only plain and simple, but various in form and color, and iridescent and incrustated. There are plates plain, fluted, and with handles, in the various colors and in different shades of the same color. There is a great variety of ornamental cups and vases, and bottles of all sizes and shapes known to any people. (See CESNOLA.) The manufacture of glass was introduced into Rome in the time of Cicero. During the reign of Nero great improvements were made and

FIG. 1.—Theban Glass Blowers.

are painted in yellow the names and titles of the same monarch. Ornaments imitating precious gems in color and beauty show that the art had been brought to a high degree of perfection by the Egyptians. Not only was glass used by them in making drinking vessels,

great skill was attained in the production of ornamental articles. At this early period only articles of luxury were produced, chiefly vases and cups for the tables of the wealthy, or urns

FIG. 4.—Cesnola Collection of Cypriote Glass in the Metropolitan Museum of Art, New York.

and lachrymatories for their tombs. In the 3d century articles of glass were in common use. Numerous specimens of Roman glass have been found in the ruins of Herculaneum and Pompeii. From these it appears that glass was used for admitting light to dwellings in Pompeii, although other houses had window frames filled with a kind of transparent talc. The great perfection which the art had attained among the Romans is attested by the celebrated Barberini or Portland vase in the British museum, said to be the most beautiful example known of glass of two layers. This vase was found about the middle of the 16th century in a marble sarcophagus near Rome, and is supposed to have been made as early as 138 B. C. After having been for more than two centuries the principal ornament in the Barberini palace in Rome, it was purchased by the duke of Portland for £1,029, and placed in the British museum. Here it was broken by a madman into many pieces, which were afterward joined together

with great skill. The vase is about 10 inches high, and is composed of two layers of glass, the under one being of a deep blue color and the other of opaque white. The raised figures appear in white upon a beautiful background of blue, and by some are supposed to represent the marriage of Peleus and Thetis.—In the 13th century, and for several centuries after, the Venetian was the best and the most famous glass in commerce. The principal works were at Murano, one of the islands adjacent to Venice. Here the manufacture was long successfully prosecuted, being sustained by the fostering care of the government, and its workmen being invested with extraordinary privileges. Glass mirrors were probably first made here, and they became famous all over Europe, gradually taking the place of the mirrors of polished metal which were before in use. Many of the ornamental objects they produced were exceedingly ingenious, and are reproduced and admired even at this day. The Bohemians next acquired reputation in this art; and owing to the purity of the materials found in abundance in their country, as well as

FIG. 5.—1. The Portland Vase. 2. Opposite figures enlarged. 3. Device on bottom. 4. 4. Devices on handles.

to their skill, their wares still continue famous. The superiority of the Bohemians was evinced especially in the production of white glass, made with pure quartz and lime and the pot-

ash obtained by burning the trees of their immense forests. This glass was for a long time held in the highest estimation, but was destined to lose its fame when flint glass with lead was produced in England. The engraved glass of Bohemia became especially celebrated. The French, perceiving the importance of the business, early imitated the example of the Venetians, and gave extraordinary encouragement to any of the nobility who would prosecute the manufacture. In 1634 attempts were made to produce mirrors from blown glass, as was practised so successfully by the Venetians; but about the year 1666 it was found necessary to procure workmen from Venice. Works were then erected at Tourlaville near Cherbourg, which was selected from the resemblance of the locality to that of the works at Murano. In 1688 Abraham Thévard introduced in Paris the method of making large plates by casting the glass instead of blowing; he thus produced heavy plates measuring 84 inches by 50, while those previously made had barely reached in length the smaller figure named, and were necessarily thin. In 1665 the manufacture of glass was established at St. Gobain. In the

first positive allusions to the use of glass for windows were made by Lactantius about the close of the 3d century, and by St. Jerome about the close of the 4th. It is asserted by the

FIG. 6.—Venetian Glass Bottle.

18th century the business became very successful, and has continued so to the present time, the products of the establishment ranking among the first in quality in the world.—The

FIG. 7.—Engraved Bohemian Drinking Glass.

Venerable Bede that glass windows were first introduced in England in 674 by the abbot Benedict; but at this time and for many centuries afterward the use of window glass was limited to ecclesiastical structures. Colored window glass is known to have been used in churches in the 8th century; but for private houses glass long continued to be a rarity, and in England in the 12th century houses provided with glass windows were regarded as magnificent. Even in the 16th century in England and the 17th in Scotland only the dwellings of the wealthy were provided with glass. The manufacture of window glass, according to an old builder's contract brought to light by Horace Walpole, and copied into his "Anecdotes of Painting," was conducted in England as early as 1439; but a decided preference was given to that "from beyond the seas." It

was commenced in London in 1557; and soon afterward flint glass also was made there. The production of plate glass was undertaken in 1670 at Lambeth by the duke of Buckingham, who imported Venetian workmen. The government encouraged the enterprise by a bounty upon the glass intended for exportation; and under this protection, also extended to the different branches of the manufacture, by which the cost was reduced from 25 to 50 per cent., many other glass factories sprung up in different parts of the kingdom; but their prosperity and the progress of the art were afterward greatly checked by the excise duties imposed, and the surveillance of crown officers over all the operations of the works. The bounties and the duties, with their annoying restrictions, were abolished in 1845, when the suddenly increased demand for home consumption brought into existence many more establishments. Their capacity for production became immense, as is shown by the fact that the firm of Chance and co. executed the large order in sheet glass for the crystal palace in 1851 without materially affecting their ability to fill their general orders. The quality of the English crown glass is unrivalled.—Glass appears to have been one of the earliest branches of manufacture introduced into the United States; but to what extent it was carried on in early times is unknown. In Salmon's "Modern History" (London, 1746), vol. iii., p. 440, mention is made of glass works which were commenced at Jamestown, Va., and the completion of which was interrupted by the Indian massacre of March 22, 1622; and in Howe's "Historical Collections of Virginia," p. 39, is a quotation from "Smith, book iv., p. 18," in which, under date of 1615, it is said that "for a long time the labor of the colony had been misdirected in the manufacture of ashes, soap, glass, and tar, in which they could by no means compete with Sweden and Russia." In Felt's "Annals of Salem," Mass., reference is made to the "Glasshouse Field," so named from the fact that in 1639 and 1640 several acres of land were appropriated to Ananias Conklin and others for the purpose of aiding them in the manufacture of glass, which was carried on for a considerable period. About 1750 works were established by Germans at Germantown, Mass. (now a part of Quincy), for the manufacture of bottles, but they were burnt before the revolution. But the first glass factory in the United States of which we have a precise account was built by Mr. Robert Hewes of Boston, in the town of Temple, N. H., in 1780. It appears that the works were established there on account of the cheapness of fuel and labor. In the winter of 1780-81 they were destroyed by fire. From a reference to this subject by Washington in his diary (1789) it would appear that glass was made at that time in New Haven. It is believed that in Salem and in Hewes's works only bottles and ordinary ware were made, and that the first window glass was

manufactured in Boston. In 1787 a company was incorporated for the manufacture of crown glass, and after numerous embarrassments the first glass was made in 1793, under the superintendence of a German named Lindt. The shares of the company attained a high value, and the Boston crown glass became celebrated for its excellence. The subsequent failure of the company was owing to the mismanagement of a board of directors who attempted to substitute American for German clay, and made other expensive and unsuccessful experiments; among these was the expansion of their business by the erection of other works for making thin crown glass at South Boston and sheet glass at Chelmsford. Works were established by the New England crown glass company for the manufacture of that article in East Cambridge about 1825, and others for bottles and for flint glass about the same period. Other crown glass works were erected in New York and other states at subsequent periods, but all were discontinued many years ago. The New England glass company, established in 1817 at East Cambridge for the manufacture of flint glass, is still in existence, and has gained a wide reputation for the excellence of its wares. Besides these works, the chief establishments for the manufacture of flint glass in the United States are in Sandwich, Mass., Brooklyn, N. Y., and Pittsburgh, Pa., and its vicinity. Sheet glass is made in Lanesborough, Mass., New Jersey, New York, Pennsylvania, and in a few places in the western states. The first plate glass manufactory was established at Cheshire, Berkshire co., Mass., about 1853. The company afterward removed their works to Lenox in the same county, and became known as the "Lenox Rough Plate Glass Company." They have the machinery for making polished plate glass, but have not yet produced it in large quantities. Henry R. Schoolcraft was employed in his youth in the works at Cheshire, and in 1817 he published a treatise entitled "Vitrology," designed to exhibit the application of chemistry to this art.—Glass is a chemical compound of variable ingredients, different substances of similar character replacing each other to produce its varieties. Silicic acid or silica is its principal element, which combines with the potash, soda, oxide of lead, lime, alumina, and other substances that may be added, to produce silicates of these bases. By the manufacturer the bases are classed as fluxes. Boracic acid may take the place of silicic acid to produce vitreous borates or glass. The proportions of the bases named admitting in their use of indefinite variations, a wide scope is given for the exercise of the skill of the manufacturer in producing any particular quality of glass. The metallic oxides also afford him abundant resources for imparting any desired hue to his product, according as these are judiciously selected and introduced. The important requisite in all the varieties of glass is a fusible

compound, which solidifies on cooling into a transparent mass, without assuming a crystalline structure. Such a substance is a product of the process of reducing metallic ores. The compounds produced by the glass manufacturer range from the most fusible combinations of one part of silica with two or three of soda or potash, which melt at a cherry-red heat and dissolve in cold water, to the hard and refractory silicates of lime and alumina, some of which require the powerful heat of a furnace to soften them. Potash especially increases the fusibility of glass; the oxides of lead and of zinc, and to some extent barytes, produce a similar effect, while they also add to its softness, its lustre, its specific gravity, and its power of refracting light, and do not interfere with its perfect freedom from color, unless the lead be used in excess, when it gives a yellowish tinge. Iron, in the state of the silicate of the protoxide, imparts a dark green color; but on adding a small quantity of binoxide of manganese ( $MnO_2$ ) the color disappears, as the protoxide of iron is converted into the sesquioxide ( $Fe_2O_3$ ), and the manganese, losing one atom of oxygen, becomes  $MnO$ . Other metallic oxides, as those of uranium, copper, silver, and gold, are also employed to give intense colors. Without reference, however, to substances used for imparting or removing colors, the essential materials of ordinary glass may be regarded as silica and boracic acid, the

alkalies, lime, and oxide of lead. The varieties of glass are classified by Dr. Knapp as follows: 1. Bottle glass, including the varieties worked into hollow vessels and tubes, as common bottles, glass for medicinal bottles, white bottle glass for vials, tumblers, tubes, &c. The dark-colored varieties are distinguished for their large proportion of oxide of iron and alumina, and none contain oxide of lead. The white bottle glass contains silica, soda or potash, and lime. 2. Window glass, including English crown and cylinder or sheet glass; this is a silicate of potash or soda, lime, and alumina. 3. Plate glass, differing from the preceding only by the greater purity and freedom from color of the materials. 4. Flint glass, used for grinding, &c., composed of silica, potash, and oxide of lead. 5. Crystal, for optical purposes and table ware, consisting of silica or boracic acid, potash, and more lead than the preceding. 6. Strass, the paste used for imitations of precious stones; it contains much oxide of lead, and also metallic oxides used for the colors. 7. Enamel, composed of silica, soda, and oxide of lead, but rendered opaque by oxide of tin or antimony, which form a stannate or antimoniate with the soda. To these may be added the soluble glass, which is a simple silicate of soda or of potash, or a mixture of the two silicates. The following analyses of several kinds of glass are from Knapp's "Chemical Technology:"

The second of these is a remarkable glass, being a simple silicate of potash with 10 per cent. more silica than is contained in Fuchs's soluble glass. (See GLASS, SOLUBLE.) Particles of glass are dispersed through the semi-transparent, imperfectly melted mass. The compound is not attacked by boiling water, and does not attract moisture from the air. The ingredients of

\* Relation between the oxygen of the acid and the total amount of oxygen in the bases.

glass appear to be in the proportions of chemical equivalents—results, however, obtained by practice and not by mixtures made with this view. Various causes affect the stability of the combinations and the qualities of the compounds. The alkali in window glass powdered and moistened is detected by its action upon turmeric paper, and may be partially dissolved out by long continued digestion in boiling water. Atmospheric agents sometimes remove it in part from window panes, leaving a film of silica or silicate of lime. The glass of stable windows is liable to change its appearance, and assume prismatic colors, from the action of the ammoniacal vapors upon the silica. Changes in the degree of oxidation of its metallic ingredients, which are sometimes induced by atmospheric causes, are also attended by changes of colors. Long continued cooling has the effect of changing the structure, causing it to lose its transparency and become devitrified. Its ingredients form among themselves a new arrangement of their particles, and compounds are produced which assume a crystallized structure. By remelting, the vitreous character may be restored, though with a loss of a portion of potash which was volatilized in the devitrification. In making articles of glass, and especially bottles, it is necessary to guard against this tendency to crystallize, and shorten the process of annealing on account of it. Devitrified glass was first described by Réaumur, and has hence been called Réaumur's porcelain. In consequence of the ease with which it may be made into any shape, and its tenacity and refractory nature, not unlike porcelain itself, it has been thought that it may be employed as a cheap substitute for this material, especially in many articles used in chemical laboratories.—The specific gravity of glass varies with its composition, from 2.4 to about 3.6, although optical glass of greater specific gravity is sometimes made, amounting in some instances to 5. Its density and also its refractive property are increased with the proportion of oxide of lead it contains. Brittleness is a quality that limits the alteration of the shape of glass within narrow bounds, after it has cooled; but when softened by heat while it is highly tenacious, no substance is more easily moulded into any form, and it can be blown by the breath into hollow vessels of which the substance is so thin that they may almost float in the air. It may also be rapidly drawn out into threads of several hundred feet in length; and these have been interwoven in fabrics of silk, producing a beautiful effect. In the soft plastic state it may be cut with knives and scissors like sheets of caoutchouc. It is then inelastic like wax; but when cooled its fibres on being beaten fly back with a spring, and hollow balls of the material have, when dropped upon the smooth face of an anvil from the height of 10 or 12 ft., been found to rebound without fracture to one third or one half the same height. It has the valuable property of

welding perfectly when red hot, and portions brought together are instantly united. When moderately heated it is readily broken in any direction by the sudden contraction caused by the application of a cold body to its surface. It is also divided when cold by breaking it along lines cut to a slight depth by a diamond, or some other extremely hard-pointed body of the exact form suited for this purpose; and it may be bored with steel drills, provided these are kept slightly moistened with water, which forms a paste with the powder produced. Oil of turpentine, either alone or holding some camphor in solution, is also used for the same purpose. Copper tubes fed with emery also serve to bore holes in glass. Acids and alkalis act upon glass differently according to its composition, and reference should be made to this in storing different liquids in bottles. Silicate of alumina is readily attacked by acids, and bottles in which this is in excess are soon corroded even by the bitartrate of potash in wine, and by the reaction the liquor itself is contaminated. A glass that loses its polish by heat is sure to be attacked by acids. Oxide of lead when used in large proportion is liable to be in part reduced to a metallic state by different chemical reagents, and give a black color to the glass. All glasses are attacked by hydrofluoric acid.—In 1863 a series of experiments showing the action of sunlight on glass was begun, and has since been continued, by Mr. Thomas Gaffield, a merchant of Boston, whose collection of authorities on glass and kindred subjects is more complete than any other in this country. As early as 1824 Prof. Faraday had noticed a change in color produced in glass containing oxide of manganese when exposed to the sun's rays, and this effect was attributed to the action of solar light on that ingredient. Mr. Gaffield's experiments, embracing about 80 different kinds of glass, colored and uncolored, of English, French, German, Belgian, and American manufacture, have proved that this remarkable phenomenon is not limited to glass containing oxide of manganese, but extends to almost every species of glass. That the effect is not due to heat, but solely to the actinic rays of the sun, is shown by the fact that no change of color is produced in the glass when it is exposed to heat; while on the contrary, after the discoloration has been produced by solar light, the colors thus acquired disappear under the action of heat, and the glass assumes its normal color. This process may be repeated indefinitely, the change of color being produced by solar light, and the original color restored by heat. It was also shown that the effect was not produced by air or moisture. In some specimens the change was more easily effected than in others; in some days were sufficient, in others years were required; but in almost all the change was produced. "It is very interesting," says Mr. Gaffield, "to witness any one of these series of specimens, showing, as in one of white plate, a gradual

change, commencing in a day or a few days in summer, from greenish or bluish white to a yellowish white or light yellow, a deep and deeper yellow, until it becomes a dark yellow or gold color; and in some Belgian sheet specimens a gradual change, commencing in a few weeks in summer, from brownish yellow to deeper yellow, yellowish pink, pink, dark pink, purple, and deep purple." The following statement shows the changes produced in nine different kinds of window glass by one year's exposure to the sun's rays:

KIND OF GLASS.	Color before exposure.	Color after exposure.
French white plate . . .	Bluish white.	Yellowish.
German crystal plate . .	Light green.	Bluish tinge.
English plate . . . . .	" "	Yellowish green.
English crown . . . . .	" "	Light purple.
Belgian sheet . . . . .	Brownish yellow.	Deep purple.
Dark green . . . . .	Dark green.	Brownish green.
English sheet . . . . .	Light bluish white.	Purplish white.
American crystal sheet.	Lighter " "	Light yellowish green.
" ordinary sheet.	Bluish green.	No change.

The colors named above are given from an observation of the glass edgewise, when a body of color several inches in depth is seen, whereas the usual thickness of the glass varies from one fourteenth to one quarter of an inch, and shows its color easily only when a white curtain or paper is placed behind it. The partial or entire disuse of oxide of manganese in many window-glass manufactories of late years, while it has produced an article not so light in color, has made one more permanent, which the action of sunlight changes but little, if any, in color or shade. Mr. Gaffield's experiments were also extended to showing the comparative power of the different kinds of glass to transmit the actinic rays of the sun. Of colored glasses, blue was found to transmit the most and red and orange the least.—The crude materials employed in the manufacture of glass are selected with more or less care, according to the quality of the articles to be produced. The three principal elements of which crown and sheet glass are composed are silica, soda, and lime. Of these by far the largest element is silica, which is now universally supplied in the form of sand. English crown and sheet glass generally contains about 73 per cent. of silica, and 13 each of soda and lime. On the continent less sulphate is used than in England; the component parts of foreign sheet glass may be stated at 74 per cent. of silica, 11 of soda, and 14 of lime. In both cases the remainder consists of alumina and oxide of iron. To the above ingredients it is generally the custom to add a small quantity of arsenic to assist in oxidizing any carbonaceous impurities and to promote the decomposition of the other materials, and of peroxide of manganese to peroxidize and thus reduce the coloring property of the oxide of iron present. Silica is obtained in the form of quartz sand from sea beaches and from the disintegration of quartzose rocks in the interior. It was in England once procured from

flints calcined and ground to powder, whence the name flint glass. The purest and best sand in the world for manufacturing glass is from Lanesborough, Mass., and other portions of Berkshire county. Some of it is exported to Europe, where it is known as the "Berkshire white sand," and there used in making the best qualities of glass. The grains are remarkable for their purity; in the mass they appear white, but under the microscope each grain is limpid like a clear quartz crystal. Other qualities are procured in various parts of the country. Next to the American sand in quality is that obtained from Fontainebleau in France, and much used by the French manufacturers. It is almost entirely free from iron, and is well adapted for the manufacture of white glass. The sand used by the extensive establishment of Chance and co., near Birmingham, England, is from Leighton Buzzard, Bedfordshire. Lime may be used either in the state of quicklime or in limestone of the purest qualities. Common wood ashes have been used to furnish potash, and ashes of sea plants to furnish soda; but these have been replaced by the crude alkalies obtained from them and other sources, and for some purposes refined pearl ash is employed. The carbonate of soda is also extensively prepared from common salt; and at Newcastle, England, black bottles are made from rock salt and sand from the bed of the river, with carbonate of lime of the soap works and the tank waste of the alkali makers. Sulphate of soda, the waste product of many chemical works, is successfully used, except for plate glass. Although glass can be produced from sand and alkali without any other addition, lime is a very important element, as giving to it hardness and insolubility. In flint glass this ingredient is replaced by lead, which gives greater brilliancy to the glass than lime, but, in consequence of the difference between its specific gravity and that of the other materials, is the cause of innumerable striæ. Saltpetre and binocide of manganese and arsenic also are often introduced into the mixtures with the view of promoting the same object. Alumina and oxide of iron are commonly not intentionally used; they come from the impurities of the other materials. Waste glass, called cullet, forms a considerable proportion of the raw materials in some works; it promotes the fusion and the chemical union of the silica and bases mixed with it, but must be well sorted, so that no qualities be introduced inferior to that intended to be made.—In melting glass, the raw materials, thoroughly ground, mixed together, and sifted, are well incorporated with from one quarter to one third of their weight of broken glass before being introduced into the melting pots. These are already heated to a white heat in the furnace, and receive only two thirds of a charge at a time, more being added as the first portion melts down. The pot being at last filled with the melted "metal," the heat is raised as rapidly as possible, and the progress

of the operation is judged of by the workmen dipping iron rods from time to time into the mixture and examining the appearance of the drops withdrawn. A nearly homogeneous product, which becomes transparent on cooling, indicates that the most refractory ingredients have been all dissolved. Their mixture has been facilitated by the continual disengagement of carbonic acid gas, which in its escape caused the whole to be thrown into ebullition. Some of the gas remains in the mass, rendering it spongy and full of vesicles. Unless in the manufacture of the finer qualities of glass, for which the purest materials are employed, there is also a scum, called glass gall or sandiver, floating upon the surface, consisting of the insoluble matters, and the sulphates of soda and lime not taken up by the mixture. This is removed by ladling, and the "metal" is next fined, which is done by increasing the heat to the highest degree, and keeping the contents of the pots in a state of perfect fluidity from 10 to 30 hours; in this time the bubbles disappear and the insoluble matters settle to the bottom. The furnace is then allowed to cool until the metal has become viscid, so that it may be taken out and worked; and it is afterward kept at sufficiently high temperature to maintain the glass in this condition, that it may be used as required. The arrangements of the great circular glass furnaces, with their central fire surrounded with eight to twelve pots, each reached by its own arch under the general dome, admit of enough material being melted at once to employ all hands the first four working days of the week, the men working day and night in six-hour shifts. The materials of the furnaces and pots, in order that they may withstand the excessive heat and the action of the various melted ingredients, must be carefully selected from the most refractory substances, and the work must be most skillfully executed. The construction of the great melting pots is an object of special solicitude, and the placing of a new one in the furnace while this is in operation is a task of no little apparent difficulty and danger. In England

Fig. 8.—Melting Pots.

they are made of the best Stourbridge fire-clay, mixed with about one fifth part of ground potsherds. The work is done entirely by hand, no machinery having yet been invented for that purpose. An average-sized pot is about 4 ft. high, 4 ft. in diameter at top, and somewhat

smaller at the bottom, and will contain about 25 cwt. of melted glass. The average duration of a pot in the furnace is about eight weeks. In the case of window and ordinary bottle glass, the pot is a plain round vessel open at the top; but in melting flint glass, it being necessary to protect the metal from all external impurities, the top of the pot is made in the form of an arch or hood, with a small opening on one side near the top, which corresponds with the nose hole of the furnace, and from which the workman withdraws the melted glass. Ordinarily two kinds of furnaces are used in addition to the annealing oven, one for melting the glass, and the other for reheating it at different stages during the process of manufacture. One of the most important improvements in the manufacture of glass has been the adoption of the Siemens regenerating gas furnace. (See FURNACE.) The novelty of this system consists in taking up the waste heat from the furnace in large chambers, and using it for raising to a higher temperature the elements of combustion. The whole of the fuel, except the inorganic portions, is converted into gas, not in the furnace itself, but in adjacent "producers." The gas and air passing through separate chambers, and having each been heated to a high degree in the waste-heat chambers, meet on entering the furnace, and there ignite, producing a heat of wonderful intensity. The advantages of this system are a greater intensity of heat produced from less fuel, and, what is very important in the manufacture of glass, a degree of cleanliness which cannot be attained by the older methods of melting. The intensity of the heat produced is indicated by the fact that in a sheet-glass furnace containing 1,800 cubic feet, materials for about 16 tons of glass in eight large pots are melted and refined into a liquid mass in 25 hours.—Such is a mere outline of the means employed to bring the materials of glass into their desired combination. The production of each kind of glass is a separate branch of manufacture, involving many curious details and processes, too numerous even to be named in this account. The tools employed are few and simple, and differ but little from those described in the work of Blancourt "On the Art of Glass," published in London in 1699. The first in importance is the pipe or blowing tube, made of wrought iron, 4 or 5 ft. long, with a bore from  $\frac{1}{4}$  to 1 in. in diameter, a little larger at the mouth end than at the other. It is a long hand, partly covered with wood, with which, the end being heated red hot, the workman reaches into the pot of melted matter and gathers up the quantity he requires, and which afterward holds the article in the manipulations to which he subjects it; and it is at the same time the air tube through which the breath is forced to expand the vessel, or through which water is sometimes blown to produce the same effect by the steam it generates. A solid rod of iron, called a punty or pontil, serves to receive the

article upon its end when freed from the pipe, adhesion being secured by the softness of the glass or by a little red-hot lump already attached to the punt. Spring tongs, like sugar tongs, are used to take up bits of melted glass; and a heavier pair, called pucellas, furnished with

FIG. 9.—Tools used in Glassmaking.

1. Pipe or blowing tube. 2. Pucellas. 3. Shears. 4. Pucellas with wooden blades. 5. Spring tongs. 6. Battledore.

broad but blunt blades, serve to give shape to the articles as the instrument in the right hand of the workman is pressed upon their surface, while, seated upon his bench, he causes with his left hand the rod holding the article to roll up and down the two long iron arms of his seat, upon which it is laid horizontally before him. At the same time the vessel is also shaped from the interior as well, and is occasionally applied to the opening of the furnace to soften it entirely or only in some part to which greater distention is given by blowing. The pucellas are sometimes provided with blades of wood, as at 4, fig. 9. Another important instrument is a pair of shears, with which a skillful workman will cut off with one clip the top of a wine glass, as he twirls it round with the

FIG. 10.—Glass Maker's Chair.

rod to which it is attached held in the left hand. The edge softened in the fire is then smoothed and polished. Besides these a wooden utensil called a battledore is employed, with which the glass is flattened by beating when necessary; compasses and calipers and a

measure stick are at hand for measuring; and a slender rod of iron forked at one end is used to take up the articles, and carry them when shaped to the annealing oven, in which they are left for some time to be tempered. (See ANNEALING.) The marver (Fr. *marbre*, marble) is a smooth polished cast-iron slab, upon the surface of which the workman rolls the glass at the end of his tube in order to give it a perfectly circular form. Those used in the manufacture of common black bottles are furnished on one edge with several concavities, in which the mass of metal taken from the melting pot is first roughly shaped as it is rolled over and over and made to swell by gentle blowing. One of the most ordinary forms into which glass is manufactured is that of bottles, which are made in moulds by the process of blowing, the kind of glass generally used being the ordinary green or window glass, and flint glass. The method of making bottles is described and illustrated in the article BOTTLE. Bottles for champagne and aerated waters are made of extraordinary strength, and are sometimes tested by the pressure of water before being used.—Of the various kinds of glass in common use, none require more care to insure the purity of the materials employed than the crystal or flint glass, of which are made many choice articles for domestic purposes, some of which are subjected to the processes of cutting or grinding and polishing. It possesses the properties of great transparency and high refractive power, which fit it for lenses for optical instruments. Flints calcined and ground were formerly used to furnish the silica, but pure sand is now generally used in its stead. Oxide of lead enters largely into its composition, and to this are due its brilliancy, density, and comparative softness. The oxide should be especially prepared to insure its purity. Oxide of zinc has been found to produce similar effects. The fusion must be rapid and at intense heat, and this must be reduced as soon as the metal is thoroughly melted and refined by the escape of the bubbles of gas, or the product acts upon the alumina and iron of the pot, and is thus so contaminated as to be worthless. The furnace is usually circular in form, and contains from four to ten pots, in front of each of which there is an opening for the workman. In the manufacture of articles of domestic use made of flint glass two processes are in use, blowing and pressing, the latter being very common in the United States. By the former method a mould is sometimes used, as in the case of bottles, when the operations are similar to those described in working ordinary green glass; or the article may receive its symmetrical form from the skill of the workman unaided by any mould. This process may be illustrated by describing how a wine glass in three parts is made. The workman, having gathered on the end of a blowpipe the requisite amount of glass (1, fig. 11), rolls it on the marver and expands it by blowing into the tube until it assumes the form shown at 2, and after-

ward, being flattened at the end with the battledore, that at 3. A lump of glass is now attached to the flat end of the bowl (4), which the workman with the pucellas, while rotating the pipe on the long arms of the chair in which he sits, transforms into the shape shown at 5. A globe is now attached to the end of this stem (6), which is afterward opened and flattened into the form represented at 7. A punty tipped with a small knob of hot glass is next stuck to the foot of the wine glass, which is severed from the blowpipe at the dotted line shown at 8. The top of the glass is then trimmed with shears (9), after which it is flashed and finished as at 10. It is now severed from the end of the punty by a sharp blow and carried by a boy to the annealing oven on the end of a forked rod. In the manufacture of articles by the method of pressing, a hollow mould is used made of steel or iron, with its interior surface so designed as to give the object the required shape and figuration. This mould may be in one piece or consist

rubbed with a wooden tool while rotated on the arms of the workman's chair; after which it is taken on a fork to the annealing oven. By this process articles can be produced with a rapidity not attainable in the case of blown glass, and therefore with less cost; but the

Fig. 12.—Hand Press.

Fig. 11.—Process of Making a Wine Glass.

of several parts, which are opened when the moulded glass is taken out. The process will be illustrated by describing the production of a tumbler. A lump of glass is gathered from the pot on the end of a punty by the "gatherer," and being held over the open mould, a sufficient quantity is cut off with a pair of scissors by another workman and drops into the mould. This is now pushed under a hand press, and a smooth iron plunger is brought down into the mould with such force that the hot glass is made to fill the entire space between the inside of the mould and the plunger, whose size and shape are the same as those of the interior of the tumbler. The plunger being raised up, the mould is taken from the press and turned over, when the tumbler is made to drop out bottom side up. A punty with a piece of hot glass at one end is now attached to the bottom of the tumbler, which is heated at another furnace and smoothed by being skilfully

latter is generally preferred.—The glass commonly used for window panes is one of the hardest varieties, and of unsuitable quality for shaping into vessels or manufacturing by cutting or grinding. Besides plate glass, which is also used for windows of a more expensive character, there are two kinds of window glass, known as crown and sheet from the different processes of manufacture; the former being first blown into a globe or sphere and flattened out into a circular disk, while the latter is formed into a cylinder which is afterward opened out into a sheet. In making crown glass, the workman gathers from the pot on the end of a blowpipe the requisite amount of molten glass, which is usually about 9 lbs. The pipe being cooled to admit of handling, the lump is rolled upon the marver to give it a conical form, and a boy blowing at the same time through the tube causes the glass to swell. It is now heated by holding it in the furnace, and is then again rolled and enlarged by blowing. The most of the glass is worked down to the end of the conical or pear-shaped lump, the upper part being hollow. The solid end is called the bullion. This being softened in the furnace, the tube is laid across a rest and twirled around, while the glass is blown into a globe. During the expansion it is important to keep the bullion point in a line with the axis of the pipe. This is done by a boy holding against the bullion point a piece of iron terminating in a small cup, while the workman constantly twirls and blows through the pipe resting upon an iron support. The globe at the end of the tube is now pointed toward the flame of the furnace, and being constantly twirled, the end toward the fire flattens out, the bullion point still forming a prominence of thicker metal in the

centre. To this centre a punty with a lump of molten glass at its end is next attached, and the blowing pipe is separated by applying a piece of cold iron around the nose. As it breaks away it takes a portion of glass with it, leaving a circular opening. Taken up by the punty, the glass is held with the nose (or portion to which the blowing pipe had been attached) presented to the nose hole of the furnace. Here it is softened almost to melting, while it is all the time twirled around; it is then presented to the flame issuing from the great circular opening of the flashing furnace, the man holding it being protected from the fire by a covering over his head and face. Rapidly revolving in this flame, the opening in the end grows larger; the heated air within prevents the two opposite faces of the flattened spheroid from coming together, and the centrifugal force is constantly enlarging its diameter. The opening rapidly increases, until the glass becomes a flat circular disk, which being removed from the fire is kept rapidly revolving until it is cool enough to retain its form. The punty is then cracked off, and the disk or table is removed upon a fork to the annealing oven and set upon edge with the rest, arranged in rows and supported by iron rods so as not to press against each other, and the thicker part in the centre, called the bullion point or bull's-eye, also keeping the tables apart and open for the circulation of air. The annealing is completed in from 24 to 48 hours. Tables are thus commonly made of 54 inches diameter, and some have been produced of 70 inches; but the difficulty of manipulation and the uncertainty of the result render the making of very large sizes unprofitable. A pot containing half a ton commonly produces 100 tables; and in the crown glass houses it is customary to empty eight such pots in three days every week. From the annealing kiln the tables are taken to the warehouse and sorted according to their different qualities and defects. Each one is then laid in turn upon a "nest" or cushion, and is divided by the diamond into two pieces, the larger one containing the bull's-eye. These are next cut up into rectangular panes. The shape and the bull's-eye involve considerable waste in cutting; and numerous other defects are found in many of the sheets. These, however, are compensated for by the remarkable brilliancy of surface peculiar to glass made in this way, which is attributed by some to the influence of the marver, and by others to the effect produced by flashing the surface. Crown glass is also free from the undulations, or cockles, which often disfigure the surface of glass made by the cylindrical process.—In the manufacture of sheet glass two furnaces are generally used, one for melting or making the glass, and the other for reheating it during the process of blowing. The latter is usually of an oblong form, with four, five, or six holes on each side for as many workmen. On each side of this furnace is a pit about 7 ft.

deep, 16 ft. wide, and as long as the furnace; over this at intervals of about 2 ft. are erected in front of each hole of the furnace wooden stagings or platforms, upon which the workman stands when swinging the cylinder to and fro and over his head. The manufacture of this kind of glass may be divided into three processes: 1, blowing the cylinder; 2, flattening it out into a sheet; 3, polishing the sheet. The first step is to gather from the pot a lump of melted glass of the required weight, which experience enables the workman to do with great accuracy. Dipping the end of a blowpipe into the melted metal and twirling it round, he gathers a pear-shaped lump of 2 or 3 lbs. After this has cooled to a dull red, it is again dipped into the glass in the pot, and a larger amount withdrawn. Thus by degrees a sufficient quantity is collected, usually about 20 lbs., to produce a sheet of glass of the required size. When this mass has become somewhat cooled, the workman places it in a block of wood so hollowed as to allow the lump of glass when placed upon it to be

FIG. 13.—Blowing Cylinder Glass.

blown to the required diameter of the cylinder. Here, while a stream of cold water is turned upon the block to prevent the wood from being burnt and the glass from being scratched, the workman revolves the pipe, and blows through it, occasionally raising it to an angle of about 75°, until he has formed a hollow pear-shaped mass, with its largest diameter, which is the same as that of the finished cylinder, next to the pipe. It is now taken to the blowing furnace, where after being heated it is swung to and fro in the pit and round in a vertical plane over the head of the workman, who stands upon the platform above mentioned and keeps the lengthening cylinder full of air by occasionally blowing through the tube. Uniformity of thickness and of diameter, which was determined by the wooden block, is secured by the skill of the workman, who when the metal runs out too freely holds the cylinder vertically

above his head, still keeping it well filled with air. This operation is skilfully continued until a cylinder is produced about 11 in. in diameter and about 50 in. long, closed at one end and attached to the blowpipe at the other. The next step is to open the end of the cylinder, which the workman does by filling it with air and, after closing the aperture of the pipe with his thumb, exposing the end to the heat of the furnace. The heat expands the air in the cylinder, which bursts open at the end where the glass is the softest. The aperture thus made is widened to the required diameter by rapidly revolving the cylinder at the furnace hole, the pipe resting on an iron support, and subsequently holding it in a vertical position with the open end downward until the glass is cooled sufficiently to retain its shape. The cylinder is now laid upon a wooden rest, or trestle, and detached from the pipe by touching with a piece of cold iron the pear-shaped neck near the nose of the pipe, and gently striking the pipe; an opening about three inches in diameter is thus formed. This end, the cap of the

FIG. 14.—The Cylinder in Different Stages of Manufacture.

cylinder, is now taken off by winding around it a thread of hot glass, and after removing it applying a piece of cold iron to any point which the thread covered. After trimming the other end by cutting off about two inches in length with a diamond, the cylinder is split open longitudinally by drawing along its inside surface a diamond attached to a long handle and guided by a wooden rule. Formerly this splitting was done with a red-hot iron, which is still sometimes used. The cylinder is now taken to the flattening oven, where it is placed, with the slit uppermost, upon the flattening stone, from the irregularities of whose surface it is protected by a sheet of glass. The cylinder soon becomes heated and opens out into a wavy sheet, the movement being accelerated by the iron rod of the workman. The surface of the sheet is next rubbed with a piece of wood attached to the end of an iron rod for the purpose of removing the irregularities of the surface. The flattening stone is now moved on wheels to the adjoining annealing oven, where the sheets are

placed for annealing, which usually requires from 24 to 36 hours. From the annealing oven the sheets are taken to the warehouse, where they are smoothed, polished, assorted, and cut into panes of the required dimensions. The former method of grinding and polishing sheet glass by imbedding the sheets in plaster of Paris proved inadequate to remove the defects in the glass consequent upon the mode of manufacture. The chief of these was the undulating or wavy appearance of the surface, called cockles, which was attributed to the difference of diameter between the inner and outer surfaces of the cylinder, and which caused objects seen through the glass to be distorted. Notwithstanding the glass was made very thick after the superficial roughness was removed, the result was a thin sheet much inferior to plate glass. The ingenious process devised by Mr. James Chance for producing patent plate glass, which is now used in England and most factories on the continent, is one of the most important improvements in the manufacture. By removing the thin outer surface of the glass by this method, an evenness and a polish are secured, even on the thinnest sheet, which make it in many respects equal to plate glass, and far superior to the sheet glass produced by the old process. The improved method consists in placing the sheet to be ground and polished upon a flat surface covered with a piece of damp soft leather or cotton cloth. A slight pressure applied to the glass causes it to adhere to the surface of cotton or leather, and by thus producing a vacuum the entire sheet is firmly maintained in a flat position by atmospheric pressure. The exposed surfaces of two sheets fixed in this manner are rubbed against each other in a horizontal position by machinery, emery and water being constantly supplied to keep up the friction. Both sides of the sheet are polished in this manner, with only a slight diminution of the thickness of the glass. After the removal of the sheets from these surfaces, they resume by their own elasticity their original shape, which is often more or less curved. The final polish is given to the sheets by a process similar to that used in polishing plate glass. In each process through which the glass has passed, it was exposed to some imperfection, and some of the sheets bear the peculiar defects of them all and are of little value; others are suitable for inferior uses, and but few are perfect. The wide difference between the quality of the best and the worst sheets is indicated by the fact that the former are valued at three times more than the latter. The same kind of material is used in the production of both crown and sheet glass. The remarkable brilliancy of surface of the former gives to it a certain advantage over sheet glass; but the larger size easily attained in making the latter gives it the supremacy in commerce. Of crown glass it is difficult to obtain panes of  $34 \times 22$  in., while the usual size of the sheets of cylinder glass is  $47 \times 32$  in., and

cylinders are occasionally blown 77 in. in length, requiring about 38 lbs. of glass. The largest sizes are only produced by the most skilful workmen. The relative antiquity of the two processes of making crown and sheet glass is involved in no little obscurity. The cylindrical process is the only one mentioned by Theophilus, who is supposed to have lived in the 12th century, and this method was long retained by the Venetians and the Bohemians, as being best adapted to the production of their colored glasses on account of the uniformity of thickness and of color secured. But in the north of Germany, France, and England, it fell into disuse, and the rotary principle prevailed exclusively. Subsequently the latter was abandoned on the continent, but held its supremacy in England, where crown glass was used for houses of the better class, while the use of sheet glass was limited to inferior dwellings. In 1832 the improved process of making cylinder glass was introduced into England from France, and subsequently the improved method above mentioned of polishing the sheets was adopted. The cylindrical method is the one now in general use in England, much of the glass being known in commerce as patent plate.—The building or factory for the manufacture of plate glass is generally of very large size. That of the British plate-glass works at Ravenhead, where it is called the foundry, is 339 ft. long by 155 wide; while the famous *halle* of St. Gobain in France is 174 by 120 ft. In the centre is the square melting furnace, with openings on two parallel sides for working purposes, while along two sides of the great building are arranged annealing ovens, which are sometimes 30 by 20 ft. in order to receive the immense plates that are to be annealed. Two kinds of pots are used, the ordinary one, open at the top, for melting the glass, and cisterns or cuvettes, in which the molten glass is carried to the casting table. In France the cuvette is usually of a quadrangular form, with a groove in each of its sides, or, as in the case of the larger cisterns, in two parallel sides, in which the tongs or iron frame are fitted when the cuvette is moved. Between each two pots in the furnace are placed, according to their size, one or more cuvettes. In some establishments the cuvette is not now used, the metal being poured from the pot in which it is melted on to the casting table. In France 16 hours are allowed for the melting, and the same time for the metal to remain in the cuvettes; but the latter term is often extended in order that the *aëriform* bubbles may escape and the excess of soda become volatilized. Toward the last the temperature is allowed to fall, and the glass then acquires the slight degree of viscosity suitable for casting. The molten glass is transferred from the pots into the adjacent cuvettes by means of wrought-iron ladles with long handles. When the glass is in the proper condition to be cast, the "tongs carriage," consisting of two powerful bars of

iron united like two scissors blades, and resting upon two wheels, is pushed into the opening made in the furnace, and the cuvette is clamped in the quadrant formed at the extremity of the tongs, two workmen manipulating the handles at the other extremity. The cistern thus taken from the furnace, while filled with molten glass, is placed on another carriage and quickly conveyed to the casting table. This consists of a massive slab, usually of cast iron, supported by a frame, and generally placed at the mouth of the annealing oven. At the Thames works in England the casting plate is 20 ft. long, 11 ft. broad, and 7 in. thick. Formerly these tables were of bronze, and the great slab of St. Gobain of this alloy weighed 50,000 lbs.; but cast iron was found less liable to crack, and is now generally used for this purpose. On each side of the table are ribs or bars of metal, which keep the glass within proper limits, and by their height determine the thickness of the plate. A copper or bronze cylinder about a foot in diameter, resting upon these bars, extends across the table. After being heated by hot coals placed upon it,

FIG. 15.—Casting Table.

the table is carefully cleaned preparatory to casting. The cistern containing the melted glass is raised from the carriage on which it was brought from the furnace by means of a crane, its outside carefully cleaned, and the glass skimmed with a copper sabre. The cuvette is now swung round over the table, over which a roller covered with cloth is drawn to remove all impurities, and the molten glass poured out in front of the cylinder, which being rolled from one extremity of the table to the other spreads out the glass in a sheet of uniform breadth and thickness. The operation is a beautiful one from the brilliancy of the great surface of melted glass, and the variety of colors exhibited upon it after the passage of the roller. While the plate is still red hot about two inches of its end is turned up like a flange, against which an iron rake-like instrument is placed, and the plate is thrust forward into the annealing oven, the temperature of which is that of dull redness. Another plate is now immediately cast upon the hot table, and the annealing oven when filled is closed and left for about five days to cool. The process of casting is done so systematically and with such despatch in a well regulated estab-

ishment, that the glass has been taken from the furnace, cast, and put into the annealing oven in less than five minutes. From the annealing oven the plates are taken to the warehouse, where they are carefully examined to see how they may be cut to the best advantage. In different manufactories and at different times various processes have been in use for grinding and smoothing the surface of plate glass, but the principle has been the same in all, viz.: rubbing the surface to be smoothed with another surface either of glass or iron, and at the same time applying sand or emery of different degrees of fineness and water between the two impinging surfaces. One of the most approved methods of grinding and smoothing the plates was introduced into England in 1856, and adopted in the British plate-glass works. This apparatus consists of a revolving table, 20 ft. in diameter, fixed upon a strong cast-iron spindle, and capable of running at an average speed of 25 revolutions a minute. Above the table frames are arranged to hold the plates of glass, which are laid in a bed of plaster of Paris, with the face to be polished resting upon the table. These frames also revolve on their centres by the friction of the table upon the glass, slowly, but so as to present each side of the plates they hold to an equal amount of rubbing as they are moved nearer to the centre of the table or further from it. Sand and water are applied to facilitate grinding down the glass. The grinding by this process is found to be even and equal, and the machinery to work smoothly and steadily from the facility with which the plates accommodate themselves to the power applied. After grinding they are smoothed with emery powder of finer and finer qualities, and are thus prepared for polishing. By the process above described the grinding and smoothing are done by the same machine; but formerly two sets of apparatus were required for this purpose. By grinding the surface of the plate is made true, but presents a rough appearance which is removed by the process of smoothing. At this stage it is somewhat opaque, and this defect disappears after the final process of polishing. This is performed chiefly by machinery. The plate of glass having been fixed upon the table by means of plaster of Paris, the surface is subjected to the action of a series of wooden blocks covered with felt and attached to a frame by which they are made to move over the surface of the glass. At the same time a polishing powder, generally red oxide of iron, is applied, while the friction may be increased by adding weight to the rubbers. Polishing sometimes brings out defects which were before concealed; the plates are consequently again assorted, and, if need be, reduced to smaller sizes. (For the methods of silvering them, see MIRROR.) Bending the large plates or the smaller sheets of glass for the purpose of fitting them for bow windows, &c., is an especial branch of the manufacture. A core of refractory material

and suitable shape is introduced upon the floor of the furnace; and upon this is laid the sheet to be bent, which as it softens by gravity conforms itself to the shape of the bed upon which it is laid. The value of plate glass varies greatly with the size. In the United States the price of a plate of standard British or French glass, 5 × 3 ft., is about \$35; but when the dimensions are double, the plate being 10 × 6 ft., the price is increased to about \$175. A plate 14 × 8 ft. is valued at about \$500. —No glass is of such importance in the arts as that of which the lenses of optical instruments are made. Both flint and crown glass are applied to this use, but each of them has its defects. The former, from the great difference in the densities of its ingredients, is with much difficulty obtained of homogeneous structure, an essential requisite in all glass used for optical purposes; and the latter is difficult to procure of uniform composition and texture, from the high temperature required for its fusion and the consequent tendency to devitrify in cooling; or if this is obviated by an increased proportion of alkali in the composition, the excess of this causes attraction of moisture from the air and a damp surface to the lens. The best flint glass is subject to defects, chief among which are undulatory appearances called *striae*, resulting from a want of uniform density in the glass, and tending to refract and disperse in different directions the rays of light passing through it. These defects are of great importance when the glass is to be used for optical purposes. In 1753 John Dollond, an English optician, first began the construction of achromatic object glasses, formed of two kinds of glass of different density, in accordance with the theory announced not long before by Euler. For this purpose Dollond used fragments of flint and of crown glass, but did not succeed in making object glasses with a larger aperture than 2 or 3 in. in diameter; and when the need of telescopes of greater magnifying power was strongly felt, it was difficult to produce flint glass sufficiently free from *striae* for a lens 4 in. in diameter. The scientific bodies of France and England offered prizes for the attainment of this result, and the most renowned glass manufacturers at the end of the last and the beginning of the present century endeavored to solve the problem. This was done by Guinand of Switzerland, a man not conversant with science, nor even a glass manufacturer, but an optician. By methods of his own he made the furnaces, crucibles, and mixtures he employed, and produced the glass, which he shaped and polished, giving without knowledge of mathematics the requisite proportion to the curves of its surface, and completed lenses of flint glass of great perfection of structure, 9 in. in diameter. The secret of his success in making the glass is believed to have consisted in keeping the mixture agitated by stirring when at its greatest liquidity, and then suffering it to cool and anneal in the pot. From

the most perfect portions of the comparatively homogeneous mass thus obtained, the lenses were cut out by a process similar to that of sawing blocks of stone. By one of the sons of Guinand the secret was imparted to M. Bontemps; and in 1828 lenses were made in France of 12 to 14 in. diameter. In 1848 Bontemps went to England, and in conjunction with the Messrs. Chance and co. made disks of flint and of crown glass larger than any before produced. At the exhibition in London in 1851, a disk of flint glass was exhibited by Messrs. Chance and co. 29 in. in diameter and weighing 2 cwt.; and at the Paris exposition in 1855 they exhibited one of the same diameter made of crown glass. One of these was afterward sold to the French government for £1,000. They are of pure color, and of such homogeneous structure that the light is transmitted without polarization. Prof. Faraday, one of a committee appointed by the astronomical society of London to experiment upon the means of producing optical lenses, while Guinand's secret method of making these 6 in. in diameter was exciting the admiration of the scientific world, discovered the heavy glass called by his name (composed of protoxide of lead 104 lbs., silicate of lead 24, and dry boracic acid 25), which has proved of considerable importance in investigations connected with the polarization of light; but its liability to change unfits it for general optical uses. Lenses both of flint and of crown glass are used in the object glasses of achromatic telescopes, serving by their combination to counteract the unequal tendency of each to disperse the rays of light. It seems to be conceded by scientific men that the glass best adapted to achromatism would be a flint glass possessing a smaller refractive power and a larger dispersive index, and a crown glass having, conversely, a greater refractive power and a less dispersive index.—The annual production of plate glass in Europe may be stated in round numbers at upward of 10,000,000 sq. ft., of which about 4,000,000 sq. ft., valued at about 28,000,000 francs, is produced in France, 3,750,000 in England, 1,500,000 in Germany, and 1,000,000 in Belgium. The industry is limited to a few large establishments, there being six each in France and England, and two each in Germany and Belgium. In addition to the above, large quantities of rough plate glass are made in England for horticultural and other cheap purposes. About 15,000,000 sq. ft. of window glass, of the value of about 15,000,000 francs, is produced annually in France, and about 100,000,000 bottles, valued at about 20,000,000 francs; the production of flint glass amounts to about 15,000,000 francs, and of ordinary table glass about the same. The entire production of the country exceeds 75,000,000 francs. The exports of glass from England in 1872 were 2,131,924 sq. ft. of plate glass, valued at £243,780; 113,004 cwt. of flint, valued at £300,484; 760,836 cwt. of common

bottles, valued at £373,138; and other kinds of glass to the value of £204,593. The latest statistics on the manufacture of glass in the United States are afforded by the census of 1870, as follows:

KINDS.	No. of establishments.	Hands employed.	Capital.	Annual products.
Cut .....	29	285	\$186,700	\$470,875
Plate .....	5	200	195,700	355,250
Stained .....	13	170	148,500	297,480
Ware, not specified.	114	12,308	10,885,882	14,300,949
Window .....	35	2,859	3,244,560	8,511,808
Total .....	201	15,822	\$14,111,642	\$19,245,862

The establishments were chiefly in Pennsylvania, New York, New Jersey, and Ohio. Of the five manufactories of plate glass, three were in Ohio and one each in New York and New Hampshire. Not included in this statement is the Lenox rough plate glass company at Lenox, Mass. The importations of glass and glass ware into the United States for the year ending June 30, 1873, amounted to \$5,834,712, including cylinder, crown, and common window, \$2,759,728; cylinder and crown polished, \$21,217; fluted, rolled, or rough plate, \$34,180; cast polished plate not silvered (2,482,359 sq. ft.), \$1,550,857; cast polished plate silvered (2,392,274 sq. ft.), \$823,076; other manufactures, \$2,230,986. Of the cylinder, crown, or common window, \$2,181,044 worth came from Belgium and \$451,223 from England; of the cast polished plate not silvered, 1,955,666 sq. ft., valued at \$1,252,991, from England, 246,698 sq. ft., valued at \$155,450, from Belgium, and 39,047 sq. ft., worth \$22,963, from France; of the silvered plate, 2,297,049 sq. ft., valued at \$764,913, was the production of England.

—COLORED AND ORNAMENTED GLASS. Moulded or pressed glass never exhibits its full lustre or the clearly cut configurations of the mould. This defect is remedied by the process called cutting glass, which is in reality grinding and afterward polishing it. It is easily effected upon the soft flint glass by applying the surfaces to be cut to the face of revolving disks of iron or copper fed with emery, or, for coarse grinding, with sand and water. Stones are also used instead of the metallic disks. The marks of the rough grinding are removed by a smooth grindstone, and the polishing is then completed by wooden disks, to which pumice or rotten stone, and finally the preparation of tin and lead called putty powder, are applied. The fine polishing of chandelier drops is effected by a lead wheel supplied with fine rotten stone and water. Glass globes and lamp shades acquire their interior ground surface by the wearing action of sand placed within them, the globes being themselves introduced into the interior of a drum which is caused to rotate rapidly. Letters and designs are engraved on glass by the use of small disks of copper set in rapid revolution by means of a lathe operated by the

foot of the workman, or by machinery, and fed with fine emery mixed with oil. Lead disks are used for the polished work. The object to be engraved is skilfully pressed against the revolving wheel or disk by the workman, who is guided by the outlines of the design lightly traced upon the glass. The art of engraving was practised by the ancients. By a recent American invention glass may be engraved by means of a blast of sand directed upon it. (See SAND BLAST.) Pleasing effects are produced by engraving through an outer casing of colored glass into an interior white, transparent, or enamelled glass; this is afterward decorated with gold and painted in arabesques or other patterns. This work is chiefly the produce of Bohemia, Bavaria, and France. Etching is also applied to the ornamenting of glass, a process which is effected by the property of hydrofluoric acid to eat into the material, as described in the article FLUORINE. The glass is first covered over with a varnish that resists the action of the acid, and when this coating is dry, the lines to be etched are marked through it by means of a point. The acid is then poured on, and is allowed to remain till it has produced the desired effect. The difficulties and danger attending the use of the acid restrict this process to the ornamenting of large polished plates, and to the labelling in indelible letters of the bottles of chemists and apothecaries. Work done by this method is inferior to that done by the regular process of engraving. An improvement upon this process has been made by Maréchal, by employing solutions of the neutral fluorides of the alkalis. The addition of hydrochloric acid to these solutions disengages hydrofluoric acid, which, coming in contact in the nascent state with the silicic acid of the glass placed in the liquid, rapidly produces a clearing upon the surface exposed. The French companies of St. Louis and Baccarat have adopted this process, by which very rich and artistic designs have been produced.—The colored glasses are produced either upon the colorless composition called strass for imitations of precious stones (see GEMS, ARTIFICIAL), or by introducing the various oxides used for coloring into the materials of flint or other kinds of glass. In the latter case the coloring matter is thoroughly fused with the glass, which therefore becomes colored throughout its entire body. Pigments are also applied to the surface of glass, and sometimes by their greater fusibility are burnt or melted in. Flint glass may be employed for vessels ornamented with colors, and to 6 cwt. of it the following ingredients are added for producing the respective colors: soft white enamel, 24 lbs. arsenic, 6 lbs. antimony; hard white enamel, 200 lbs. putty, prepared from tin and lead; blue transparent glass, 2 lbs. oxide of cobalt; azure blue, about 6 lbs. oxide of copper; ruby red, 4 oz. oxide of gold; amethyst or purple, 20 lbs. oxide of manganese; common orange, 12 lbs. iron ore and 4 lbs. manganese; emerald green, 12 lbs. copper scales and 12

lbs. iron ore; gold topaz color, 3 lbs. oxide of uranium. The colors produced by the metallic oxides are found to vary with the degree of heat employed. All the colors of the spectrum may be obtained with oxide of iron; and these various results do not seem to depend upon the different degrees of oxidation, but are thought to result from variations in molecular arrangement, induced perhaps by the action of light. By another process the surface alone of the glass may be colored. This is done by first gathering with the blowpipe a lump of clear glass, which after being rolled upon the marver is dipped into a pot of melted colored glass, forming a lump of colorless glass enveloped in a coating of colored glass. This is blown into a globe or cylinder and opened out into a sheet or plate in the usual manner, one surface of which is clear and the other colored. Vessels of various kinds having colored surfaces on the outside may be produced in a similar manner. By cutting through the thin layer of colored glass to the colorless layer, a great variety of colored ornamental glass may be produced. By gathering first a lump of colored glass and then coating this with melted clear glass, the external surface of the vessel will be colorless and the inner layer colored. "Casing" is a somewhat similar process. The article of flint glass when partially blown is inserted into a thin shell of colored glass, prepared at the same time for its reception, and the blowing is continued till the inner one fills the shell, with which it is afterward well incorporated by softening in the furnace and further blowing. Several partial casings of different colors may be thus applied.—In making etched enamelled glass, the enamel substance is ground to an impalpable powder, and laid with a brush in a pasty state upon the glass. After the paste is dried, the ornament is etched out by machinery or by hand, and the glass is then softened till the enamel is vitrified and incorporated with it. From this it is removed to the annealing kiln. The flocked variety of enamelled glass is prepared by the same method, except that a fine, smooth, opaque surface, like satin, much softer and smoother than that of ground glass, is previously given to the whole surface before the enamel is applied. This variety has in great part supplanted the other, and is justly much admired for the softening of the light diffused through it, and for the delicacy and beauty of the elaborate and artistic designs with which it is ornamented.—The Venetians and the Bohemians have long been celebrated for their skill and ingenuity in the production of ornamented glass. Many of the ingenious effects produced are imitations of ancient manufacture, of which many wonderful specimens are preserved in European museums. The process of drawing out tubes is an interesting one. The workman, having gathered a lump of glass on the end of a blowpipe, expands it into a globular form with very thick walls. Another workman having

attached a punty to the opposite end, the two men separate from each other as quickly as possible, thus elongating the glass into a tube. The globe immediately contracts across the centre, which, being drawn out to the size of the tube desired, cools, so that the hotter and softer portions next yield in their dimensions, and so on until a tube of 100 ft. or more hangs between the men. It is kept constantly rotating in the hands, and is straightened as it cools and sets by placing it on the ground. It is cut into suitable lengths while hot by taking hold of it with cold tongs. The diameter of the bore retains its proportion to the thickness of the glass; hence thin tubes must be drawn from globes blown to large size, or from small ones containing very little metal. In producing canes the glass is drawn out without being blown. Tubes thus drawn out from colored glass are converted into beads by other curious processes. This branch of the manufacture is extensively practised at Murano. The tubes are drawn out 150 ft. in length, and to the diameter of a goose quill, those for the smallest beads by the workmen receding from each other at a pretty rapid trot. The tubes are cut into lengths of about 27 in. and assorted for size and color. Women or boys then take several together in the left hand, and run them on the face of an anvil up to a certain measure, and with a blunt steel edge break off the ends all of the same length, which is commonly about twice the diameter of the tubes; the bits fall into a box. These are next worked about in a moistened mixture of wood ashes and sand, with which the cylindrical pieces become filled; and they are then introduced with more sand into a hollow cylindrical vessel, which is placed in a furnace and made to revolve. The glass softens, but the paste within the bits prevents their sides from being compressed; they become spherical, and their edges are smoothed and polished by the friction. When taken from the fire and cleaned from the sand, they are ready to be put up for the market. The Vene-

ornamental articles. In making this kind of glass, pieces of plain, colored, or opaque white cane, of uniform length, are arranged on end, the different colors alternating, around the interior of a cylindrical mould. The selection and the arrangement of colors depend upon the taste of the manufacturer. The mould and the pieces having been subjected to a moderate heat, a solid ball of transparent flint glass, attached to the end of a blowpipe or punty, is placed within the mould, the various canes forming an external coating to the glass, to which they become welded. The ball is now taken from the mould, reheated, and marvered till the adhering canes are rolled into one uniform mass. This being covered with a gathering of clear glass, the lump thus formed, with the ornamental work in the interior, may be drawn into canes of any size and presenting either the natural or the spiral arrangement; the latter being effected by the workmen rotating the glass in opposite directions while drawing it out into a cane. By variously arranging the colors in this process, and by skilful manipulations, many wonderful and ingenious effects are produced. Beautiful vases are also made by the above process, the glass when prepared being blown into that form instead of being drawn into canes. The *mille-fiori* consists of a variety of ends of variously colored tubes, cut in the form of lozenges, which, having been arranged to represent flowers or other ornamental design, are enveloped and massed together with transparent glass. The lump is then worked into the required form, a very common one being hemispherical for use as paper weights. Portraits and even watches and barometers have been represented in the interior of glass; but in this case these articles and the glass have not formed a homogeneous mass, the former being arranged in a cavity of the latter. Mosaic glass is produced by arranging vertically side by side threads or small canes of variously colored opaque or transparent glass, of uniform lengths, so that the ends shall form a ground representing flowers, arabesques, or any mosaic design. This mass is now submitted to a heat sufficient to fuse the whole, all the sides at the same time being pressed together so as to exclude the air from the interstices of the threads. The result is a homogeneous solid cane or cylinder, which, being cut at right angles or laterally, yields a number of layers or copies of the same uniform design. This process was practised with great skill by the ancients, who are supposed to have produced pictures in this way; but in existing specimens, the pieces have been so accurately united by intense heat or otherwise, that the junctures cannot even be discovered by a powerful magnifying glass. *Vitro di trino* represents fine lace work with intersecting lines of white enamel or transparent glass, forming a series of diamond-shaped sections, each containing an air bubble of uniform size. In making this, a lump of glass is blown

FIG. 16.—Manufacture of Filigree Glass.

tian filigree glass, which consists of spirally twisted white and colored enamel glasses cased in transparent glass, is much used for the stems of wine glasses, goblets, &c.; and when arranged side by side in alternate colors, it is manufactured into tazzas, vases, and other

in a mould, around the inner sides of which are arranged pieces of canes of the required colors, as described in the case of filigree glass, which, adhering to the glass, form ribs or flutes on its external surface. The lump, having been twisted to give the spiral arrangement to the adhering canes, is formed into a conical shape and opened at the base. This forms the inner case of the *vitro di trino*. A corresponding outer case is formed in the same manner, which being turned inside out, the projecting canes appear on the inside of the cup with a reversed spiral arrangement. One case is now placed within the other, and both being reheated are collapsed together, forming uniform air bubbles between each white enamel-crossed section. The two cases, thus welded into one, may be formed into the bowl of a wine glass or other vessel. Frosted glass, like the preceding, is one of the few specimens of Venetian work not made by the ancients; and although the process of making it is exceedingly simple, it was considered a lost art until recently practised at the Falcon glass works in England. The appearance of irregularly veined, marble-like projecting dislocations, with intervening fissures, is produced by immersing the hot glass in cold water, quickly withdrawing it, reheating the ball of glass, and simultaneously expanding it by blowing. Cameo incrustation is also of

FIG. 17.—Cameo Incrustation.

modern origin, having been first introduced by the Bohemians. The figure intended for incrustation must be made of materials requiring a higher degree of heat for their fusion than the glass to be used. The figure, having been heated, is introduced into a cylindrical-shaped piece of glass, attached at one end to a blowpipe and open at the other. The open end is then closed, leaving the figure in the interior of the hollow pocket. The air is now exhausted through the hollow tube, which produces a collapse and causes the glass and figure to form into a homogeneous mass. In making "paper weights," thin sections of little ornamented rods are placed in a circular iron

mould or bed, in the form of the required design. A workman presses a piece of hot glass on the end of a punty into the mould and takes up the design. Then another workman drops a piece of hot glass on the opposite side of the design. The whole is now taken to the furnace, where the parts are welded into a hemispherical form, which magnifies the interior design and presents a fine picture enclosed within the transparent setting. In making spun glass, the workman heats one end of a tube of glass, white or colored, by the flame of a lamp, and seizing the softened end with a pair of pincers draws out a long thread. Owing to the extreme ductility of glass, these threads can be drawn to an extraordinary fineness and length. In some cases spun glass has been made to imitate the hair of animals.—Among the most valuable treatises on the subject of glass are "Curiosities of Glass Making," by Apsley Pellatt (London, 1849), and *Guide du verrier*, by G. Bontemps (Paris, 1868), both of these authors having been for many years extensively engaged in the manufacture of glass. Among other works are those of Neri, "The Art of Glass" (translated, London, 1662); Shaw, "The Chemistry of Porcelain, Glass, and Pottery" (London, 1837); Henry Chance, "On the Manufacture of Crown and Sheet Glass" (London, 1856), and "On the Manufacture of Glass" (1868); Peligot, *L'Art de la verrerie* (Paris, 1862); Turgan, *Les grandes usines de France* (Paris, 1862-'70); Cochin, *La manufacture des glaces de Saint-Gobain de 1665 à 1865* (Paris, 1865); Gaffield, "Action of Sunlight on Glass," reprinted from the "American Journal of Science and Arts" (New Haven, 1867); Sauzay, *La verrerie* (Paris, 1868), and "Wonders of Glass Making in all Ages" (London and New York, 1870); and *Rapports du jury international* of the Paris universal exposition of 1867, vol. cxi. (Paris, 1868).

**GLASS, Soluble, or Water Glass**, an artificial silicate of soda or potash, or a double silicate of both these alkalies. It may be formed by fusing 8 or 10 parts of dry carbonate of soda or potash with 15 parts of white sand or powdered quartz or flint. Nearly all glass is to a slight extent soluble in water, in consequence of the alkaline matter it contains; and the solubility is increased by raising the temperature of the water, which under pressure may be carried far above the boiling point. Water holding caustic alkalies in solution will attack glass vessels containing it in consequence of the formation of a soluble alkaline silicate. It is to this quality of solubility that feldspar ordinarily owes its value as a fertilizing ingredient of the soil; and it is from the affinity of caustic lime for silica that it may be used for liberating the alkali in the feldspar. Attention was first directed to soluble glass by Fuchs as a suitable composition for rendering combustible bodies fire-proof; and in 1824 portions of the new theatre in Munich were coated with it. He also employed it in the style of fresco paint-

ing called stereochromy, for fixing the colors (see FRESKO PAINTING); and it was used not only upon plastered walls, but with success by Echter directly upon the sandstone of the Strasburg minster. Fuchs proposed to render wood fire-proof, and even linen also, by means of it; to protect surfaces from the action of the weather; to prepare with it artificial stone; and to use it as a cement for glass and porcelain. But it appears to have been most successfully applied by Prof. Kuhlmann at Lille, who employed it to prevent the decay of walls and edifices, even when built of very inferior stone, and in print works and tapestry factories for fixing colors upon cotton and paper. In England it is employed in the fabrication of the celebrated Ransome artificial stone, described in the article CONCRETE and in Dr. F. A. P. Barnard's report of the Paris universal exposition of 1867. Soluble glass is also employed by Baerle and co. of Worms for washing wool. Forty parts of water are mixed with one of soluble glass at a temperature of from 122° to 135° F., and the wool is stirred in the mixture for a few minutes. It is then rinsed in tepid water, when it is found perfectly clean, white, and odorless, without having lost any of its softness or other valuable qualities.

**GLASSITES.** See SANDEMANIANS.

**GLASS PAINTING.** The art of painting upon glass is supposed to be of Byzantine origin, and to have arisen since the beginning of the Christian era. The first authentic account of the subject is given in the *Diversarum Artium Schemata*, a work written by Theophilus, probably in the 12th century, though by some authorities its date is assigned to the 10th. The complete description given in this treatise of the process of painting on glass justifies the conclusion that the art itself must have been invented at a much earlier period; but the oldest specimens now existing do not date further back than the beginning of the 11th century. Indeed, the oldest existing specimens to which a date can with certainty be assigned has been considered by M. de Lasteyrie and other French antiquaries to be the windows in the cathedrals at Angers and St. Denis, which were painted about the middle of the 12th century. The skill of the French painters on glass was extolled by Theophilus, and to the present time France has continued to be the richest storehouse of painted glass of the earliest style. The process described by Theophilus continued to be practised until about the middle of the 16th century, when the art reached its zenith. The most eminent painters practised it, as Albert Dürer, Bernard Palissy, and others, and their works are still admired in the churches of that period, as the Cologne cathedral, York minster, and many others. But in the next century the art had entirely declined, for the reason, as Labarte suggests in his "Illustrated Handbook," that its intention was perverted in the transformation of an art of purely monumental decoration into an art

of expression. For this oil painting possessed greater resources, and glass painting necessarily fell into neglect. In some modern attempts it is remarked that the primary object of the glass in transmitting light appears to be overlooked and sacrificed in the opaque shadows introduced. In the ancient glass pictures the figures were formed of pieces of stained glass, and the shadows were laid on with dark colors and fixed in the fire. Intense colors were exclusively employed, the ruby and blue always predominant. The ground was mosaic in circles, squares, and lozenges, of massive forms, and filled with foliated ornaments in the Roman style. Over this were medallions representing historical and biographical subjects from the lives of the saints. When figures came to be introduced, they were generally grotesque and distorted; but the costumes were remarkably correct. The designs always harmonized with the style of architecture, stately and magnificent in the Norman structures, and light and elegant in those of the early English models in the 13th century. In these the brilliant positive colors were made more subsidiary, appearing in borders, geometric bands, and central points, while the ground was of a neutral gray produced by lines crossing each other at right angles. The designs were also more correctly drawn, and shaded with greater delicacy. For the violet tint always before used for the faces of the figures was substituted a gray or brown upon colorless glass. The pieces of glass were of larger size, and a single figure was often made to occupy a whole window, standing beneath an elaborate blue or red canopy. In the background, among the architectural fragmentary designs, still appeared the old Roman foliated ornaments, but intermixed with original studies from nature, a style of the art which was afterward carried to great perfection. Not only leaves, plants, and trees, but even landscapes and buildings in perspective, appeared in the latter half of the 15th century. The Scripture pieces were often explained by legends painted upon the phylacteries, and in the background were represented rich blue or red hangings of damask.—After a long decline, the 19th century has witnessed a revival in the art of painting on glass, which is now extensively practised in France, Germany, and England, the finest specimens being produced at Munich. In earlier periods it was devoted chiefly to ornamenting cathedral windows with sacred illustrations, but it is now used for general purposes of ornamentation, embracing a wide range of secular subjects. The belief in the superiority of ancient glass painting, which was even regarded by some as one of the lost arts, has been superseded by the opinion held by the highest authorities that painted glass can now be manufactured superior to the best specimens of the middle ages. Indeed, the processes then in use have been brought to light by modern research. In 1850 a series of chemical analyses was in-

stituted by Mr. C. Winston of England, who during his life made the subject of painted glass in its antiquarian aspects a special study, and the earliest specimens were carefully analyzed. The results reached made it easy to reproduce both the quality and the color of the ancient glass.—Glass painting, which is more properly a process of staining, differs from all other styles of pictorial art, except the painting of porcelain. The colors are different, being wholly of mineral composition, and are not merely laid on the outside, but fixed by being fused into the material, undergoing in the operation chemical changes that develop the brilliancy and transparency of which the compounds are susceptible. The colors are mixed with a flux of much easier fusion than the glass, and with some vehicle, as boiled oil or spirits of turpentine. The mixture is usually laid on with a brush as in ordinary painting; and the glass being then exposed to heat, the flux melts and sinks into the body. None of the clear bright colors are perceived until the work is completed, and the artist consequently labors under great disadvantage in applying the materials that are to produce them. He is guided either by lines drawn on the back side, which show through, or by a cartoon or drawing on paper placed there. In the early use of glass for windows, especially those of churches, brilliant colors were highly esteemed, and great success was attained in the methods of coloring. A bright red color was imparted by the ancients with the protoxide of copper. In later times it was found impracticable to succeed with this on account of the tendency of the copper to pass to a peroxide and produce a green tinge; but the practice has been again introduced with success by the Tyne company in England, at Choisy in France, and in other places. The discovery of the preparation of gold and tin, called purple of Cassius, also afforded another means of producing a brilliant red.—In the history of the art two leading processes have been prominent. From the earliest period until about the middle of the 16th century the method described by Theophilus and known as the mosaic system prevailed. In this process the glass was colored in the manufacture, and blocks of different colors having been brought together, the outlines and shading of the design were produced by the application of an enamel color. About the time mentioned it was discovered that all colors besides yellow, brown, and light red, which had previously been imparted by this method, could be given to glass by means of the enamel process; but the works produced by this method were greatly inferior to those by the mosaic system. There has been a spirited controversy between the advocates of the German method of glass painting, in which enamel is used, and the English glass painters, who avoid the use of enamel as far as possible, as it sometimes scales off. It seems to be conceded that the beauty of the cathedral glass of the 13th and

14th centuries was in the brilliancy of the glass and the skilful arrangement of designs and colors, and not in any enamel work. The ordinary method of glass painting, as practised in England, is to use for the colored parts of the design pieces of glass differently colored in the process of manufacture, and to employ only one enamel color, brown, for tracing the outlines and painting the shadows of the picture upon the glass. The enamel brown, like any other enamel color, consists of coloring matter mixed with pulverized glass, called flux or enamel. When this is laid on the surface of the glass and heated in an oven or furnace, it melts, in consequence of being more fusible, while the glass is merely at a red heat; on being cooled it hardens and produces a permanent color on the surface of the glass. The general colors of the design, therefore, are not produced by the painter, but by the glass maker; the former, as has been stated, using pieces of glass already colored. The only exception to this is in the case of yellow, which is produced on the glass by applying a "stain," the principal ingredient of which is oxide or chloride of silver. On being exposed to the action of a red heat, the yellow stain penetrates the glass and imparts to it its tint, the preparation of silver being afterward brushed off. This process was discovered in the early part of the 14th century, and has been used to impart a yellow tint to uncolored and most kinds of colored glass. The various tints of yellow are the only ones that can be produced on glass without altering its surface. By putting on a second or third coating of the silver oxide and burning in, orange and red stained glasses are produced.—The process of producing a painted glass window is an interesting one. The artist first makes an outline on a small scale of the stone work of the window, within which he sketches the design, indicating the colors to be used and the general treatment of the subject. A full-sized drawing or cartoon is next made, from which a "cutting drawing" is traced, showing the lines where the strips of lead are to go, and omitting all other details. On this latter drawing, on which the colors of the design are indicated by outlines, the pieces of different colored glass are laid and cut with a diamond, each piece being cut out of that particular color or tint required. The artist now arranges the pieces of different colors in their proper places on the cartoon, and traces the outline of the design upon them. On being heated in an oven, the opaque lines vitrify and are formed indelibly on the surface of the glass. After the outlines have been thus "burnt" on, the glass is taken again to the painter, who covers the cartoon with a sheet of colorless glass, or if large a portion of it at a time. Thus having the cartoon for a guide, he arranges in their proper places on the sheet of colorless glass the pieces on which the outlines have been traced, and secures them firmly with drops of melted resin and

beeswax, or other suitable substance. The sheet of colorless glass, with the pieces thus arranged adhering to it, is placed upon an easel, and the shadows of the picture are put on with the same material as that used in tracing the outlines. The shading, however, is not traced from the cartoon, as were the outlines, but is done by the skill and experience of the painter. When the shading is completed, and the tints of yellow, if any are required, are put on, the pieces of glass are detached from the colorless sheet and again subjected to heat, for the purpose of "burning in" the shadows. If more work by the painter is required, the process is repeated, the glass being thus subjected to heat in some instances six or seven times. The work of the painter being completed, the finished pieces are taken by the "leader," who, having arranged them by the aid of the "cutting drawing" so as to form the entire design, fastens them together by means of strips of grooved lead skilfully fitted around the edges of the several pieces. If the window is a large one, as is generally the case, it is divided into parts of convenient size, which are fitted together when the window is put in its place. Bars of iron are also sometimes placed across the window at the line of junction and at other convenient intervals. This general process of producing mosaic stained glass windows has been in use from the earliest times, though it may have been modified in some of its details; and until some other method of imparting colors to glass without detracting from its transparency and brilliancy is discovered, the opaque lead lines in the design must be accepted as a necessity. In his "Art of Glass Painting," Mr. C. Winston says: "The necessity of leading a glass painting together is one of those conditions which cannot be evaded by any ingenuity. The lead work and saddle bars must be accepted as necessary parts of the composition. The design must be made with reference to them, and that glass painting must be acknowledged to be the best which admits of the leads being thrown into the outlines, and made to serve as outlines; and which by the simplicity, I might almost say roughness, of its design and execution, prevents the harshness of the saddle bars from being obtrusive. In this respect the glass paintings prior to 1550, and until the 18th century, must be considered superior to those later works in which the attempt has been made to ignore the leads and saddle bars, by leading the work together in squares independently of the outlines of the composition, or by twisting the saddle bars so as to avoid their cutting the design at regular intervals; because both methods immediately suggest the idea of a blemished picture, and make us immediately perceive how much better the work would be without leads or saddle bars. But a window cannot be constructed without them; hence it is better to adopt them as essential parts of the design; and the beautiful windows of the choir of this [Lich-

field] cathedral, which bear date between 1532 and 1539, show that a design so constituted is compatible with high pictorial effect." Another condition which must be particularly observed is the preservation of transparency in the highest degree consistent with the production of a picture. For this purpose the high lights of the window must be as free from shading as possible. Indeed, light shading throughout the entire design is one of the conditions imposed by the nature of the material. These conditions were fully recognized by the artists of the middle of the 16th century, and this fact accounts largely for the superiority of their productions to those of their predecessors. In the best glass paintings of that period there is always an abundance of light in the upper portion of the window, while in the choice of subjects and their general treatment the artist selected those that could be made the most effective with the least shading.—Among numerous works on this subject are: Lasteyrie, *Histoire de la peinture sur verre d'après des monumens en France* (2 vols., Paris, 1838-'56); Gessert, *Geschichte der Glasmalerei* (Stuttgart, 1839); Ballantine, "Treatise on Painted Glass" (London and Edinburgh, 1845); Bontemps, *Peinture sur verre au dix-neuvième siècle* (Paris, 1845); Weale, "Ancient Painted and Stained Glass" (London, 1846); Winston, "Inquiry into the Difference of Style observable in Ancient Glass Paintings, especially in England, with Hints on Glass Painting" (London, 1847), and "An Introduction to the Study of Painted Glass" (Oxford, 1849); Warrington, "History of Stained Glass" (London, 1848); Fromberg, "An Essay on the Art of Painting on Glass" (London, 1851); Bielfeld, "A Guide to Painting on Glass" (London, 1856); and Winston, "Memoirs illustrative of the Art of Glass Painting" (1865).

**GLASS SNAKE** (*Ophisaurus ventralis*, Daud.), a North American reptile, improperly called a snake, belonging to the order *saurophidia* of Gray, and to the chalcidian or cyclosaurian

Glass Snake (*Ophisaurus ventralis*).

family of saurians of Duméril and Bibron. The head is lizard-like, sub-oval, with rounded snout, covered above with numerous polygonal plates, large anteriorly, the frontal the largest;

the tongue arrow-shaped, triangularly grooved in front, free in its anterior extremity, on which the papillæ are granular; the nostrils are near the snout, lateral, opening upward; the eyes are small, protected by two movable unequal lids; there are several rows of short conical teeth, about 36 in number, on the roof of the mouth, chiefly on the pterygoid bones; the intermaxillary teeth are conical, the maxillary simple and nearly cylindrical, about 40 in all above and 36 below; the external ear is a small oval opening just behind the angle of the mouth. There is no distinct neck; the body is elongated and snake-like, covered with small, smooth, slightly imbricated scales, disposed in circles around the body, about 120 in number; there is no vestige of anterior or posterior limbs externally, and only their rudiments internally; there is a deep groove separating the sides of the body from the abdomen, most visible during respiration, and which doubtless affords the free movements of the ends of the ribs necessary for progression. The tail forms at least two thirds of the total length, round, and tapering gradually to the tip, covered with about 140 rings of scales. Though the shape of this reptile is snake-like, the movable lids, external auditory openings, less movable vertebrae, less extensible tongue, rudimentary sternum, and above all the consolidation of the bones of the skull and jaws, sufficiently show its saurian affinities. The length varies from  $2\frac{1}{4}$  to  $3\frac{1}{2}$  ft. The head above is mottled with black and green, with a yellowish tinge on the jaws; the body and tail above are marked with longitudinal and transverse lines of black, green, and yellow, each scale marked with these three colors; the under surface is yellowish, brightest on the abdomen; some slight varieties of color are described. It is found on the Atlantic coast from southern Virginia to Florida, and as far west as the Mississippi, Missouri, and Ohio rivers; it has been seen west of the Alleghanies as far north as Michigan. From the smallness of its gape it cannot destroy and swallow large prey, like the serpents; it cannot climb nor swim, but passes its life on the surface of dry places or in natural cavities in the ground, living principally on mollusks, insects, annelids, and other small animals, and perhaps also partly on vegetable food like the sweet potato. It can move with considerable speed, and is taken uninjured with difficulty on account of the ease with which the joints of the tail are separated; the name of glass snake was given on account of this extreme fragility. The breaking of the tail into small pieces in this and in some scincoid reptiles seems to be the result of a reflex action in the spinal cord, as an irritation of this nervous centre will cause a separation even after the tail is divided from the body. Dr. Burnett ("Proceedings of the Boston Society of Natural History," vol. iv., p. 223) ascertained that the caudal muscles in this reptile do not pass from one vertebra to another, but that a portion are in-

serted into the skin, while others terminate midway between one vertebra and the next, dovetailed as it were between the fibres sent from that vertebra, and attached to them only by the *myolemma*; so that there is no rupture of muscular fibres, but only a separation of one layer of muscles from the adjoining one, when the tail of the animal is broken; the detached portion is said to be reproduced in a year. The glass snake in its anatomical peculiarities resembles the chalcidian amphibæna and the scincoid blindworm (*anguis fragilis*).

**GLASS SPONGE**, or **Glass Rope**, a silicious sponge of the genus *hyalonema* (Gray); the name may also be properly applied to other allied genera, and especially to the *euplectella*, which will be described under VENUS'S FLOWER-BASKET. This sponge was first described and named by Dr. J. E. Gray, of the British museum, in 1835; he regarded it as a coral allied to the sea fans (*gorgonia*), an opinion to which he still adheres, against what seems to be an overwhelming mass of evidence. As usually seen, this sponge consists of a loosely twisted bundle of glassy threads, diverging at one end and converging at the other, which is more or less covered with a brown crust, studded with wart-like cylindrical elevations, terminating in radiating ridges. The threads are mainly composed of silex, and are shining, translucent, and very flexible; the fascicle varies from 12 to 20 in. in length, and is about half an inch thick, the threads ranging from the size of a bristle to that of a knitting needle. The wart-like elevations are generally regarded as polyps, of the genus *palythoa*, continuous throughout the crust, of which Dr. Gray considers the fascicle the central axis. The convergent end, in its natural state, is enveloped in a spongy mass, the fascicle on which Dr. Gray regarded as a parasite. The opinions of scientific men since Gray have been various. Prof. Brandt of St. Petersburg considered the sponge a parasite attaching itself to the polyp mass and gradually destroying it. Dr. Bowerbank regards all the structures above named as parts of one sponge, the wart-like elevations being the oscula. Prof. Schultze of Bonn represents the fascicle and the sponge mass as belonging together, the warty crust being referred to the polyp *palythoa*. Ehrenberg regards the fascicle as an artificial product of Japanese industry, and all sponges as of vegetable nature. In 1867 Prof. Loven described a little, stalked, deep-sea sponge from the coast of Norway, the *H. boreale*, which led him and naturalists since to the belief that this sponge had been represented upside down; in fact, that the glassy threads were below, mooring the structure to the sand, mud, or weeds, the sponge mass forming the upper portion; an opinion which Dr. Leidy in 1870 modified by suggesting that this sponge may be suspended by its glassy cable, thinking it highly improbable that it should be attached by or rest upon the base where the large oscula are placed. All agree that there is a sponge mass attached

to this compound animal, as the microscopic structure of the threads is perfectly characteristic of sponge spicules; their silicious character shows that they are not formed by polyps; the sponge mass at the upper end consists of an elegant tissue of dense masses of very short silicious spicules, forming

a kind of felt; the terminal sponge is more or less cup-shaped, with an open conical central cavity. All but Dr. Bowerbank admit a parasite, the question being whether the polyp is a parasite on the sponge, or the sponge a parasite on the polyp. The characters of *hyalonema* will be best understood from the annexed figure. *H. mirabile* or *Sieboldi* is found in the seas around Japan, near Yokohama; *H. Lusitanicum* was found by Prof. Bocage of Lisbon off the coast of Portugal; *H. boreale*, according to Wyville Thompson not belonging to this genus but to a corticate type, was found by Prof. Loven on the coast of Norway; and this or an allied species has lately been dredged on the northern part of our own coast. Other glass sponges are *Holtenia*, figured in the "American Naturalist" for July, 1873, and *phoronema* and *rossella*, figured in the "Popular Science Monthly" for September, 1873. Where men like Gray, Bowerbank, Brandt, and Schultze entertain such different opinions, after the examination of hundreds of specimens, during a period of nearly 40 years, it is certainly very difficult to decide whether *hyalonema* be wholly a sponge, or which, if either, the sponge or the polyp, is the parasite. Dr. Leidy, in the "American Naturalist" for March, 1870, alludes to a specimen, very much like one in the possession of the writer of this article, in which the fascicle appears to have been withdrawn from the sponge and lain for some time in the sea; a shark's

Glass Sponge  
(*Hyalonema Lusitanicum*).

egg is also attached near the top, and the tendrils of others are partially imbedded in the crust, which has no warty elevations; this seems to favor Dr. Bowerbank's opinion that the whole is a sponge, and that the crust is not made by a polyp.

**GLASTONBURY**, a market town and parish of Somersetshire, England, 25 m. S. W. of Bath; pop. in 1871, 3,670. The town occupies a peninsula, formerly an island (Avalon), in the river Brue. It derives its interest and importance almost wholly from its ruins, prominent among which are those of a famous Benedictine abbey, founded, it is said, by St. Augustine in 605, rebuilt in great splendor about a century later, and enriched by the liberality of successive princes until the time of Ethelred I. It suffered from the Danes, and before the conquest, when the Normans robbed it of both wealth and influence, had gained considerable importance and celebrity. Its half ruined walls were rebuilt by Stephen and Henry II., and its abbot was honored with a mitre and a seat among the barons in parliament. At one time it was annexed to the see of Wells, the incumbent of which was called bishop of Glastonbury. On the suppression of monasteries by Henry VIII. it enjoyed a revenue of £3,508 13s. 4½d. In 1539 Richard Whiting, the last abbot, for refusing to surrender the abbey to the king, was hanged in his robes on Torhill with two of his monks. The abbey ruins, consisting of portions of the church, the chapel of St. Joseph of Arimathea, and a building called the abbot's kitchen, are comprised in a quadrangle of 60 acres, which was once encompassed by a high wall. A reputation for sanctity clung to Glastonbury long after the reformation, and as late as 1751 10,000 invalids flocked hither in a single month, to drink from a spring said to cause miraculous cures.

**GLATZ**, a town of Prussia, in the province of Silesia, on the left bank of the Neisse, 52 m. S. W. of Breslau; pop. in 1871, 11,541. The town is defended by an old citadel, a modern fortress, and other works. It manufactures cotton fabrics, leather, and hosiery, and has a Roman Catholic gymnasium, a hospital, infirmary, and barracks. It was fortified as early as the 11th century, and has sustained numerous sieges. It was taken in the beginning of the thirty years' war by the Protestants, capitulated in 1622 to the imperial troops, and in 1742 to the Prussians.—The territory of Glatz was made a county of the empire in the latter part of the 15th century by the emperor Frederick III., and subsequently formed a part of the Austrian dominions, until occupied by Frederick the Great in 1742. A part of the Sudetic mountains is often designated by the name of Glatzer Gebirge.

**GLAUBER**, Johann Rudolf, a German chemist, born in Karlstadt in 1604, died in Amsterdam in 1668. He was a physician and alchemist, boasted of wonderful secrets, and was called the Paracelsus of his age. He passed his life

in his laboratory, successively at Salzburg, Frankfort, Cologne, and Amsterdam, first exhibited the production of artificial salts, and discovered the salt to which his name is given. He wrote voluminously on chemistry and alchemy, and his works were translated into English by C. Packe (London, 1689).

**GLAUBER'S SALT**, sulphate of soda, found native, and produced artificially. The artificial salt was named from its discoverer (see above), who obtained it in making muriatic acid. The natural salt is usually met with as an efflorescence, sometimes deposited around hot springs, as at Carlsbad and Cheltenham, or about saline ponds, as in the country between the head waters of the Arkansas and Santa Fé, on the route to the Rocky mountains. It also occurs in a cavern near a volcano on the island of Hawaii, where it is produced by the action of the volcanic heat and gases upon the sea water. It is found as an efflorescence on the limestone rocks below the Genesee falls, Rochester, N. Y. It crystallizes in forms derived from an oblique rhombic prism. The crystals effloresce in the air, and lose their water of crystallization. It is most soluble in water at the temperature of 93·2° F., when, according to the experiments of Löwel, 412·22 parts of the hydrated salt are dissolved by 100 of water; at 77° only 98·48 parts are taken up, and at 68°, 58·35 parts. The salt has a taste cool at first, then saline and bitter. It is white, transparent to opaque, of vitreous lustre, of hardness from 1·5 to 2, and specific gravity 1·481. Its composition is represented by the formula  $\text{NaO}, \text{SO}_3 + 10\text{HO}$ , making its equivalent 161, and the percentage of water 55·76. It is artificially prepared by decomposing common salt by sulphuric acid (as in the preparation of hydrochloric acid, of which process it is the residue), with an excess of acid, which is taken up by the addition of carbonate of lime. It is very largely manufactured in England and France in order to prepare from it carbonate of soda and soda ash; to avoid the production of muriatic acid, a process has been introduced of making the salt by the reaction of common salt and sulphate of iron upon each other. It is also obtained as a residuum in the manufacture of bleaching salts, muriate of ammonia, &c., and from sea water, by exposing the water to intense cold, when this, the least soluble salt, separates by crystallizing.—Sulphate of soda is principally of value as a medium for obtaining the other salts of soda. Formerly it was much used in medicine as an aperient and diuretic; but sulphate of magnesia has taken its place, though it is still sometimes used in small doses in combination with other drugs. By dissolving it in hydrochloric or dilute sulphuric acid, cold is produced, by which water may be frozen in summer; and wine coolers have been made designed for its use, in which, with 12 lbs. of the salt and 10 lbs. of acid, 10 to 12 lbs. of ice have been formed in an hour. The salt is an ingredient in some kinds of glass.

**GLAUCHAU**, a town of Saxony, in the circle of Zwickau, 15 m. W. of Chemnitz; pop. in 1871, 22,036. It contains an old and extensive castle and several churches. Next to Chemnitz it is the most important manufacturing town of Saxony. The staple articles made here are woollen and half-woollen goods, paper, and engines. The annual exports exceed in value \$15,000,000. Glauchau has 12,000 looms, and employs many persons in neighboring localities. The population has almost quadrupled within the last 40 years, and the number of master workmen has increased from 300 in 1804 to more than 2,000 in 1874.

**GLAUCUS**. **I.** Of Potniæ, the grandson of Æolus, son of Sisyphus and Merope, and father of Bellerophon. To make his mares more swift and fierce, he prevented them from breeding, and, according to some, fed them upon human flesh. This incensed the gods, and especially Aphrodite; and when Glaucus took part with his chariot and horses in the funeral games of Pelias at Iolcus, the horses in madness upset the chariot, and, according to some, tore Glaucus to pieces. He was afterward believed to haunt the isthmus of Corinth, and to frighten horses engaged in the race. One of the lost tragedies of Æschylus was named from him. **II.** Of Anthedon in Bœotia, a fisherman who ate of the divine herb planted by Saturn, and became immortal. He built the ship Argo, and was her steersman. In the sea fight against the Tyrrhenians, he alone was unhurt; he leaped overboard, sank to the bottom, and became a sea divinity. He was said to visit the coast of Greece annually, and was revered by fisherman and sailors. His many loves were a favorite subject with poets. Aristotle says that he delivered oracles at Delos, which by some were more esteemed than those of Apollo. Philostratus describes a statue of him, half man and half fish. He was often represented on the stage by the Greek dramatists.

**GLEIG, George Robert**, a Scottish author, born in Stirling, April 20, 1796. He abandoned his studies at Oxford to join as a volunteer a regiment going to Spain in 1813, and served both in the Peninsula and in America. On retiring from the army he resumed his studies at Oxford, took his degree, was ordained, and in 1844 was appointed chaplain to Chelsea hospital, and in 1846 chaplain general to the forces. His exertions to establish a system of education for the soldiers gained for him the office of inspector general of military schools. His works are for the most part histories or novels. Of the former, "The Family History of England" (1836; 2d ed., 1854) and the "Military History of Great Britain" (1845) are most esteemed; and of the latter, "The Subaltern" (1825), "Chelsea Pensioners" (1829), and "Country Curate" (1834). His eulogistic "Memoir of Warren Hastings" (1841) has been severely criticised. In 1858 he collected two volumes of his "Essays," chiefly from the "Edinburgh" and "Quarterly" reviews, and

in 1859 published his chief work, a life of the duke of Wellington (new ed., 1862).

**GLEIM, Johann Wilhelm Ludwig**, a German poet, born at Ermsleben, near Halberstadt, April 2, 1719, died in the latter town, Feb. 18, 1803. He published odes, fables, tales, and songs, which obtained for him the title of the German Anacreon. His *Siegeslied nach der Schlacht bei Rossbach* is the most famous of his battle songs. Gleim was very popular in Germany, and exercised for about 40 years a master influence on literature. He was a bachelor, but his home, kept by his accomplished niece Sophie Dorothea Gleim (celebrated in his songs under the name of Gleminde), was a favorite resort of poets and scholars. An edition of his works (7 vols., Halberstadt, 1811-'13) was completed by an 8th volume (Leipsic, 1841).

**GLEIWITZ**, a town of Prussian Silesia, on the Klodnitz, 40 m. S. E. of Oppeln; pop. in 1871, 12,939. It has a Catholic gymnasium, a Protestant and two Catholic churches, a synagogue, a convent, a hospital, and barracks, and is the centre of the mining and smelting industry of upper Silesia.

**GLENCÖE**, one of the wildest and most gloomy of the Scottish glens, in the district of Lorn, Argyshire, about 10 m. long, and enclosed by lofty mountains. The lower part of the glen near Loch Leven is cultivated and wooded, but the upper part is exceedingly rugged and barren, the mountains rising almost perpendicularly in fantastic forms, seamed with deep furrows worn by the winter torrents. A small lake, from which issues the Cona, lies in the middle of the valley. The path through the glen is lined by immense masses of rock. Near its N. W. extremity is the scene of the "massacre of Glencoe."

After the revolution of 1688 many of the Scottish clans continued in arms for King James against King William. In August, 1691, the government of William issued a proclamation offering an amnesty to such insurgents as should take the oath of allegiance on or before Dec. 31. All the chiefs submitted within the prescribed time except the aged MacIain or Macdonald of Glencoe, whose tribe, a few hundred in number, inhabited this secluded valley. On Dec. 31 he went to Fort William and offered to take the oath; but the colonel in command, not being a magistrate, could not administer the oath, and referred the chief to the sheriff at Inverary, before whom Macdonald took the oath, on Jan. 6, 1692. The

earls of Breadalbane and Argyll, and the master of Stair, who were then in London, determined to avail themselves of this unintentional delay to effect the destruction of the tribe of Macdonald, to whom Argyll and Breadalbane were hereditary enemies. The master of Stair was secretary of state for Scotland, and by representing to William that Glencoe had not submitted, and that the dwellers in the valley, whom he described as a band of robbers, were the only remaining obstacle to the complete pacification of the highlands, he obtained an order for their extirpation. It was executed with horrible treachery and cruelty. On Feb. 1 a body of 120 soldiers, commanded by Campbell of Glenlyon, was sent to occupy Glencoe. Professing peace and friendship, they were received with the kindest hospitality, and for nearly a fortnight lived at free quarters in the utmost familiarity with the people. On the evening of Feb. 12 the officers supped at Macdonald's house. That same night the massacre was begun. Macdonald and two of his attendants were murdered, and his wife received such barbarous treatment that she died the next day. About 40 persons were killed that night. Detachments of soldiers were sent to guard the outlets of the valley; but they arrived too late,

Pass of Glencoe.

and many of the inhabitants escaped half naked to the mountains, where a considerable number of the women and children perished of cold and hunger. In the morning the assassins set the village on fire, and took away with them all the flocks and herds of the valley. No punishment was inflicted on the authors of this crime. A graphic account of the massacre of Glencoe is given by Macaulay in his "History of England," vol. iv., exonerating King William. Other able writers inculcate him, and the question has been very warmly debated.

**GLENOWER**, or **Glendwr, Owen**, a Welsh chieftain, born in Merionethshire about 1349, died

Sept. 20, 1415. His father was Gryffydd Vychan, and his mother, Elena, was granddaughter of Llewellyn, the last Welsh prince of Wales. He studied law at the inns of court in London, and became a barrister, but soon quitted the profession for that of arms. He was made squire of the body to Richard II., to whom he adhered throughout his disastrous reign. In 1387 he was knighted, and at an early age married Margaret, daughter of Sir David Hanmer. After the deposition of Richard II., he retired to his lordship of Glendwrwy in Wales. His retirement was wrongfully construed into disloyalty to the new king Henry IV., and his estates were declared forfeited, and seized by Lord Grey de Ruthyn, an Anglo-Norman nobleman whose domains adjoined those of Glendower. Glendower then proclaimed himself prince of Wales, and called his countrymen to arms. The Welsh bards espoused the cause of Glendower, and he was soon at the head of a considerable force of enthusiastic partisans. In the summer of 1400 he seized the estates of Lord Grey. That nobleman in reprisal, with the help of Lord Talbot, who had been sent to his assistance by the king, surprised the residence of Glendower, who narrowly escaped capture. Rallying his followers, he pillaged and burned the town of Ruthyn, and made such progress that the king in person took the field against him. A long contest ensued, in the course of which Glendower in 1402 made prisoner his old enemy Lord Grey, whom he compelled to pay a ransom of 10,000 marks and to marry his fourth daughter, Jane; he also captured Sir Edward Mortimer, but treated him with such kindness that he became Glendower's partisan, and arranged for him an alliance with the Percys of Northumberland. The confederates agreed to divide the kingdom among themselves. Glendower then called together the estates of Wales, and was formally crowned prince at Machynlleth. In 1403 the confederates gave battle to Henry near Shrewsbury, and were defeated, Percy being killed. Glendower in 1404 entered into alliance with France, and gained some victories; but in March, 1405, he was defeated at Grosmont castle and at Mynydd pwl Melyn, losing 2,300 men. He wandered about, hiding himself in woods and caves, until the French king sent him 12,000 men, to whom Glendower joined 11,000 Welsh, and marching into England, penetrated as far as Worcester. But after several indecisive engagements the allies retreated into Wales, and shortly afterward the French returned to their own country. For some years Glendower waged a partisan and predatory war, and at the time of his death was negotiating with Sir Gilbert Talbot, who had been sent by Henry V. to offer him and his followers a free pardon. Glendower had five daughters and several sons, most or all of whom fell in battle in 1400.

**GLENGARRY**, an E. county of Ontario, Canada, bordering on Quebec and the river St. Law-

rence; area, 462 sq. m.; pop. in 1871, 20,524, of whom 15,899 were of Scotch, 2,607 of French, 1,279 of Irish, and 509 of English origin. It is watered by several streams, and is intersected by the Grand Trunk and the Montreal and Ottawa Junction railroads. Capital, Alexandria.

**GLENS FALLS**, a village of Warren co., New York, situated on the Hudson river, which is here crossed by a bridge, at the terminus of a branch of the Rensselaer and Saratoga railroad, 46 m. N. of Albany; pop. in 1870, 4,500. The surrounding country is rugged, and in the vicinity are quarries of black marble. The river, here flowing through a ravine, descends 50 ft. over a rocky precipice 900 ft. long. The village is connected by a feeder with the Champlain canal, and contains a planing mill, two saw mills, a tannery, a brewery, a flour mill, a foundry and machine shop, and manufactories of carriages, lime, pumps, &c. Elmwood female seminary and Glen's Falls academy are flourishing institutions. There are two national banks, two newspapers, and six churches.

**GLEYSRE, Charles Gabriel**. See supplement.

**GLIDDON, George Robins**, an American Egyptologist, born in Devonshire, England, in 1809, died in Panama, Nov. 16, 1857. He went at an early age to Alexandria, where his father was a merchant and also United States consul. He resided in Egypt 23 years, and was during part of the time United States vice consul at Cairo. After leaving Egypt he came to the United States, and lectured at Boston, New York, and Philadelphia, on Egyptian antiquities. At the time of his death he was agent for the Honduras inter-oceanic railway company. He was the author of "Appeal to the Antiquaries of Europe on the Destruction of the Monuments of Egypt" (1841); "Discourses on Egyptian Archaeology" (London, 1841); "Otiæ Egyptiacæ" (1849); "Ancient Egypt" (4to, London and Philadelphia, 1850; new ed., 8vo, London, 1853); "Types of Mankind," written in conjunction with Dr. J. C. Nott and others (Philadelphia, 1854); "Indigenous Races of the Earth," also with Dr. Nott and others (Philadelphia, 1857); and an essay on the production of cotton in the valley of the Nile.

**GLOBE, Artificial**, a hollow sphere, on the surface of which is delineated a map of the earth or heavens, with the various circles to which points are referred to determine their positions. Globes are thus of two sorts, terrestrial and celestial. They serve as models to impart correct ideas of the form and movements of the earth and of the heavenly bodies, of their position in relation to each other at different times, of the relative positions of places upon the earth, and of the principle of designating these by lines of latitude and longitude. Globes are also applied to the mechanical solution of various astronomical problems, as the difference of time in different places, dependent on the position of the sun in relation to those places, the times of the rising and setting of the sun at any place, and many other similar questions,

which may be approximately determined without recourse to mathematical calculations. But it is chiefly for the sake of the clear instruction in general geography, which many persons fail to derive from maps, that globes are especially valuable. It is not known when they were first constructed; but the first celestial globe is supposed to have been made by Anaximander of Miletus, a pupil of Thales, who flourished in the 6th century B. C. Ptolemy made use of a terrestrial globe provided with the universal meridian, such as is applied to those now in use. Martin Behaim, the navigator, constructed a terrestrial globe at Nuremberg toward the close of the 15th century. Tycho Brahe had one of copper nearly 5 ft. in diameter. Another was made in Venice in 1683 for Louis XIV., 12 ft. in diameter. Another, 11 ft. in diameter, constructed by Brousch of Limburg, attracted the attention of Peter the Great, who purchased it and removed it to St. Petersburg. It was large enough to accommodate 12 persons sitting around a table within it. Its inner surface was celestial, the stars being represented by gilded nails; and the outer surface was terrestrial. The national library of Paris has two globes of over 14 ft. diameter. A magnificent copper globe made for Louis XVI. is in the Mazarin library; and another of the same material and of admirable workmanship, designed by Poirson for the instruction of the king of Rome, and bought by Louis XVIII. for 36,000 francs, belongs to the museum of the Louvre. In 1851 a large globe of novel construction was built in Leicester square, London, by Mr. Wyld. It was 56 ft. in diameter, and the delineations were upon the inside only. These were modelled in slabs of plaster of Paris, which were set like a ceiling on the ribs of zinc which formed the framework of the structure. The slabs were cast in clay moulds, which were prepared with care from the most correct maps on a scale of 10 miles to the inch. About 6,000 slabs were required to cover the whole surface, their dimensions varying from two feet square as the width diminished toward the poles. The topographical features were represented in relief, and the surface painted in colors. A stairway wound around from the base, by which the circular platforms one above another were reached that brought the spectators near to the inner surface of the great shell.—The globes used by geographers in the middle of the last century were very similar to those now in use. Much attention was directed to their manufacture, and a treatise on their construction and use was published in 1769 by George Adams. The first requisite is a ball to receive the printed map; this is therefore first accurately measured, and due allowance is made for the shrinking each segment will experience after being wet. The diameter being determined, a silver-steel semicircle  $1\frac{1}{2}$  in. wide and  $\frac{1}{4}$  in. thick is next made, of precisely half this diameter less that of the wires intended for the poles. A globe of wood is now made three eighths of an inch

less in diameter than the steel circle. Into two opposite points of this so-called mould bits of No. 7 wire are inserted for poles. Dry paper is laid all over it to prevent the pasted paper to be next laid from adhering. This is of coarse heavy quality, and eight or ten layers saturated with paste are applied in succession as evenly as possible, covering the whole surface. As this coating becomes dry, it shrinks and fits tightly over the mould. It is then hung by the poles in the front edge of a bench fitted to receive it, and by applying a knife on the line of the equator while the ball is made to revolve, the shell is cut through, so that it may be taken off the mould in two hemispheres. This being done, a turned stick of right length, with a short wire in each end for poles, is introduced, one end in each hemisphere, and the two shells being brought together are secured by glueing their edges. The ball, called in its present state the foundation, is placed in the steel semicircle, and coated with a composition of glue and whiting. Being made to revolve, the excess of the composition is removed by the circle, and the ball is thus turned smooth and true, after which it is carefully dried. The next process is to lay out the lines of latitude and longitude, which is done by a beam compass, commencing with the colures and ecliptic. The first meridian is usually made to pass through the intersections of the equator and ecliptic, the points of the vernal and autumnal equinoxes; and from the former of these points the reckoning of the degrees on the equator and ecliptic begins. The maps are now to be cut on the engraved meridians of each  $15^\circ$ , thus making 24 segments; and these are pasted in succession with white paste upon the foundation, the lines drawn upon it serving as guides. The fitting requires great care, that the edges may be made to exactly coincide, and some stretching of the equatorial portions is sometimes requisite. When dry the paper covering is colored, and then sized with gelatine and immediately varnished. The final process before mounting is to dry again at  $200^\circ$  F. Holtzapffel says: "A globe is usually covered with 26 pieces of paper, namely, 2 pole papers or circles, including  $30^\circ$  around each pole, and 24 gores meeting at the equator. Sometimes the gores extend from the pole to the equator; every gore has then a narrow curved central notch extending  $30^\circ$  from the equator." The globe is hung for support by its poles in a brass circle, which goes round it and is called the universal meridian, inasmuch as any point upon the surface of the globe revolving in this may be brought under it. It is divided into degrees, which on one side are reckoned from either pole toward the equator for the purpose of giving the elevation of the poles, and on the other from the equator toward either pole, to be used for finding the latitude of places. A frame or stand is prepared to receive the globe with its brass circle, the top presenting a broad horizontal circle with two vertical slots placed

opposite each other for receiving the brass meridian, which when adjusted is free to slide around in its own plane, so that the poles may be upright, horizontal, or at any angle to the horizontal circle. Around this circle, which represents the rational horizon or imaginary plane passing through the centre of the earth, are drawn several concentric circles; the innermost represents the horizon, and the slots for the brass circle are on the N. and S. points; the degrees on the northern two quadrants are reckoned from E. and W. toward the N., and those on the southern toward the S. Outside of this is the circle representing the calendar, with the names of the months and divisions corresponding to the days. The next circle contains the signs and degrees of the ecliptic, so arranged that against each day of the year is found the point of the ecliptic in which the sun is situated. In some globes the horizontal circle is made to revolve. It is attached to arms which extend below the brass meridian and unite, supporting the adjusting clamp which supports the brass meridian. A taper pin extends down three inches from the lowest part of the arms, and fits into a socket in the iron base, thus securing by the revolutions of the meridian and horizon in their own planes the effect of a universal joint, so that any part of the globe can be brought under observation without changing the position of the base. To the N. pole of the globe is attached a small circle of brass, called the hour circle, the pole passing through its centre, and holding it so that the two move round together, but yet permitting the hour circle to be moved round by the hand upon the axis. The circle is divided into 24 equal parts, corresponding to the hours of the day, and any one of these can be placed upon any meridian by turning the circle. The quadrant of altitude is a brass slip equal in length to a quarter of the circumference, and divided into 90°. It is fastened to the brass meridian, and is used for measuring degrees in any direction on the globe. A mariner's compass is sometimes attached to the frame of the globe for the purpose of placing the meridian in a N. and S. line. The various circles connected with the terrestrial globe are equally appropriate to the celestial; and as the latter are ordinarily constructed, the observer is supposed to be looking down upon the heavens presenting a convex surface, upon which the stars and constellations are mapped in their proper relative positions. To render the nature of the imaginary circles to which the points upon both globes are referred more clear for the student, the armillary sphere was contrived, which consists of the several circles in the form of graduated brass rings placed in their appropriate positions, and containing in the centre a small globe representing the earth. These circles are the horizon, meridian, equator, ecliptic, equinoctial colure, and the solstitial colure. The sphere formed by them is supported in a frame in the same manner as the

globes.—Celestial and terrestrial globes are sometimes combined, the latter being enclosed in a glass sphere marked with the constellations. Globes are sometimes made also of India rubber or thin paper, and so contrived that they may be inflated with air. Some terrestrial globes contain, in addition to the usual geographical delineations, geological strata, atmospheric currents, isothermal lines, hydrographic information, and trade routes; and in some the land is represented in relief. Slate globes for school use are made with only the lines of latitude and longitude drawn on them; and wooden globes, painted black and similarly marked, are constructed, on which maps are drawn with chalk.

**GLOBE FISH.** See SEA PORCUPINE.

**GLOBIGERINA**, a microscopic protozoan animal, of the foraminiferous order of the class of rhizopods. The body is composed of simple sarcode or protoplasmic matter, enclosed in a shell pierced by numerous minute openings, through which a film of the animal substance is exuded, capable of throwing out small thread-like processes, or *pseudopodia*. The animals increase by budding, each sarcode mass being enveloped in its calcareous shell, but connected irregularly with all the rest of the colony; there is no definite shape, the mass being compared by Huxley to that of a badly grown raspberry. Recent deep-sea dredgings (in the Gulf stream at a depth of 3,100 ft., near the Faroe islands at a depth of 3,900 ft., off Cape Farewell, Greenland, at 7,560 ft., and between the Azores and Newfoundland at 10,000 ft., and in the north Atlantic at still greater depths in the track of the Atlantic cable) have brought up the shells of living globigerinæ from the calcareous ooze of the ocean bottom. In the compound proto-

Globigerina  
bulboides.

plasmic animal to which the name of *bathybius* has been given, are found globigerinæ, with coccoliths and coccospheres; the ancient chalk deposits are made up almost entirely, in many specimens, of remains of the three last named animals, the same as those now living on the bottom of the ocean; the great central plain of the North Atlantic, 1,000 m. wide and many hundreds in length, nearly level, is covered with a chalky mud containing innumerable globigerinæ with their attendant coccoliths and coccospheres, and the deeper the sea the larger are these animals. They doubtless constitute the food of the star fishes, which also have been dredged from these great depths. There is no reason to think that the habits and the habitats of the ancient chalk animals were different from those of the living globigerinæ; hence we may conclude that the chalk formation, constituting a large part of southern Great Britain and central and southern Europe, often 1,000 ft. thick, is the dried and elevated mud of an ancient deep sea. From the fact that this present deep-sea fauna is apparently identical with that

of the ancient chalk, there seems to be some ground for the statement that the cretaceous period at the bottom of the sea has extended to the present time. For very interesting suggestions concerning the geology and antiquity involved in the study of these animals, the reader is referred to a lecture by Prof. Huxley "On a Piece of Chalk," delivered in 1868, and published in "Lay Sermons and Addresses" (New York, 1871). (See BATHYBIUS, COCCOLITHS, and FORAMINIFERA.)

**GLOGAU**, or *Gross-Glogau*, a town of Prussian Silesia, on the left bank of the Oder, 54 m. N. W. of Breslau; pop. in 1871, 18,265. It is strongly fortified, and contains an old castle, four churches, a Protestant and a Roman Catholic gymnasium, extensive barracks, and several hospitals. It is connected by a bridge with an island in the Oder, on which stand the cathedral and a strong fortress, built in 1260. The town has manufactories of cotton, woolen, and linen goods, sealing wax, and tobacco. A principality of Glogau was founded in 1252 by the third son of Duke Henry II. of Silesia. In the following century it was made a duchy, which became extinct in 1506. The town was burned in 1420 and in 1615.

**GLOMMEN**, the largest river of Norway, rising in the mountains of the S. E. part of the province of Drontheim, near lat. 63° N., and flowing for the most part nearly due S. through several lakes, into the Skager Rack. Its length is about 360 m. The entire valley through which it flows is remarkable for picturesque scenery, cataracts, and forests of pine, producing the finest timber in Europe. From the town of Røraas to the Ojeren lake, the river is a mountain torrent. The head of navigation is at Sarpborg, about 10 m. from the mouth. The Glommen has more than 20 cataracts, the principal one being the celebrated Sarpfoss, half a mile above Sarpborg. The river, a short distance above, is divided into two branches, which flow in parallel directions to the sea. The E. branch, having forced its way through a rugged defile, reaches the brink of a precipice, where, although divided at the summit by a projecting cliff, it falls an unbroken cascade, about 75 ft. The abyss is strewn with large masses of granite, which break the volume of water into vast sheets of foam. On the brink of the fall the stream is about 120 ft. wide, and from 26 to 30 ft. deep, according to the season. The rapids, for a short distance inward, are remarkably fine.

**GLORY PEA**, a name given by Australians to plants of the genus *clianthus*, of the order *leguminosa*, especially to the species named, in honor of the navigator Dampier, *C. Dampieri*. This is found in the desert regions of Australia as a low straggling shrub with light-colored, hairy, pinnate leaves. The flowers are borne in clusters from the axils of the leaves, and are very singular in form and brilliant in color; the standard or banner petal of the flower appears in the form of an elongated shield of

the most intense scarlet color, with a boss in the centre of so dark a brown as to appear black. For many years this had been regarded as one of the most difficult to raise of all greenhouse plants, it being very impatient of any disturbance of the root, and being subject

Glory Pea (*Clianthus Dampieri*).

to the attacks of insects, but it was finally discovered that it would succeed well by sowing the seeds in the open border. They should be sown after the soil is well warmed by the sun, in the place where the plants are intended to remain.

**GLOSSOP**, a town of Derbyshire, England, 19 m. N. W. of Sheffield; pop. in 1871, 5,074, and of the borough, 17,046. It consists of an old and a new town, the former better built than the latter, and contains a fine parish church, chapels for Roman Catholics and dissenters, a town hall, and various charitable institutions. It is the chief cotton manufacturing place in the county, having more than 50 cotton mills in the town and its neighborhood, besides woollen and paper mills, bleach fields, dye and print works, and iron foundries. On a hill near the town is Melandra castle, the site of a Roman station, and a Roman road known as the doctors' gate extends from the castle to Brough.

**GLOUCESTER**. I. A S. W. county of New Jersey, separated by the Delaware river from Pennsylvania on the N. W., drained by Big Timber, Oldman's, Raccoon, and Mantua creeks; area, 280 sq. m.; pop. in 1870, 21,562. The surface is generally level and much of it covered with forests. The soil along the banks of the Delaware and for about 7 m. inland consists of a clayey loam, productive and well cultivated. Marl is found here, and iron ore is obtained near Woodbury. The S. E. part of the county is sandy and mostly unimproved. It is traversed by the West Jersey and the Swedesboro railroad. The chief productions

in 1870 were 123,181 bushels of wheat, 20,334 of rye, 457,236 of Indian corn, 27,543 of oats, 762,624 of sweet and 411,872 of Irish potatoes, 334,574 lbs. of butter, and 27,805 tons of hay. There were 4,574 horses, 5,523 milch cows, 2,415 other cattle, 2,704 sheep, and 10,382 swine; 3 manufactories of agricultural implements, 2 of boots and shoes, 10 of carriages, 5 of coffins, 2 of glass ware, 2 of window glass, 7 of saddlery and harness, 3 of tin, copper, and sheet-iron ware, 13 flour and 6 saw mills. Capital, Woodbury. **II.** A S. E. county of Virginia, bordering on Chesapeake bay, bounded N. by the Piankatank and S. W. by York river; area, 280 sq. m.; pop. in 1870, 10,211, of whom 5,429 were colored. The surface is level and the soil light and productive. Among the most important exports are oysters and fish, the taking of which employs large numbers of the inhabitants, and wood, which is sent to New York and Philadelphia. The chief productions in 1870 were 21,966 bushels of wheat, 207,240 of Indian corn, 25,856 of oats, 10,673 of Irish and 9,110 of sweet potatoes. There were 808 horses, 1,707 milch cows, 3,130 other cattle, and 8,274 swine. There were 6 saw mills. Capital, Gloucester Court House.

**GLOUCESTER**, a N. E. county of New Brunswick, Canada, bounded N. by the bay of Chaleurs, E. by the gulf of St. Lawrence, and drained by Nipisiguit and other rivers; area, 1,684 sq. m.; pop. in 1871, 18,810, of whom 12,680 were of French, 3,695 of Irish, 1,215 of Scotch, and 932 of English origin. The surface inland is diversified by hills, between which lie fertile valleys. The climate is favorable for agriculture, while the great extent of coast, off which are several islands, and the number of good harbors, afford opportunities for fishing and lumbering. Ship building is actively carried on. Capital, Bathurst.

**GLOUCESTER**, a city and port of entry of Essex co., Massachusetts, on the peninsula of Cape Ann, 30 m. N. N. E. of Boston, with which it is connected by a branch of the Eastern railroad. It formerly comprised the whole of Cape Ann, and was 8 m. long by 5 broad; but in 1840 the N. E. portion of the peninsula was formed into the town of Rockport. The city contains six distinct villages, each having a post office, viz.: East Gloucester; Annisquam, or Squam, on the N. side of the cape, which has a safe harbor much resorted to by fishing vessels; Bay View and Lanesville, noted for their fine granite quarries; West Gloucester, formerly known as West Parish, which has a beach 2 or 3 m. long, of white sand, of which large quantities are exported; and lastly, Gloucester village, or "The Harbor," on the S. side, which has one of the best ports on the coast, capacious, safe, easy of access, and with sufficient depth of water to admit the largest vessels. The harbor is formed by a peninsula, known as Eastern point, jutting out from the main body of Cape Ann in a

S. W. direction, and opens into Massachusetts bay. On the extremity of the point is a fort mounting 10 guns. Gloucester was a place of importance prior to 1800. It increased slowly until 1850, since which its growth has been rapid. The population in 1790 was 4,912; in 1800, 5,313; in 1810, 5,901; in 1820, 6,384; in 1830, 7,513; in 1840, 6,350; in 1850, 7,786; in 1860, 10,904; in 1870, 15,389, of whom 4,007 were foreigners. The principal portion of the city, in the vicinity of the harbor, is handsomely and compactly built, and very beautifully situated, with extensive and picturesque sea views, and is a fashionable summer resort for bathing and sea air. The city hall is an elegant brick building, erected in 1870 at a cost of \$115,000, and two of the school houses are large and handsome structures. Gloucester is mainly noted for its cod and mackerel fisheries, far surpassing any other port in the country in the number of vessels and men employed, and in the value of the catch. In 1865 the number of vessels engaged was 341, having an aggregate tonnage of 24,450, and employing 4,590 men; capital invested, \$1,865,700; mackerel caught, 154,938 barrels, valued at \$2,190,562; cod and other dry fish, 113,028 quintals, worth \$706,425; value of cod-liver oil sold, \$90,420. The value of all fishery products was \$3,319,457. In 1873 the catch, with the value of each item, was as follows: codfish, 460,000 quintals, \$2,070,000; other fish, 25,000 quintals, \$50,000; fresh fish, including halibut, 9,000,000 lbs., \$310,000; oil, 275,000 gallons, \$165,000; mackerel, 86,544 barrels, \$1,125,000; herring, 5,000 barrels, \$23,000; shell fish, 18,000 barrels, \$18,000; miscellaneous, \$40,000; total value, \$3,800,000. The number of vessels belonging to Gloucester engaged in fishing in 1873 was 375, with about 3,500 men, of whom but a small proportion are residents of the city. The business is attended with great risk, 236 vessels and 1,200 lives having been lost since 1830. The losses in 1873, the heaviest experienced in any year, comprised 31 vessels and 174 lives. The customs district includes the adjoining towns of Essex, Manchester, and Rockport. The value of foreign commerce for the year ending June 30, 1873, was: exports, \$1,512; imports, \$60,735. The number of vessels cleared was 127, of 13,365 tons; entered, 117, of 17,771 tons. In the coastwise trade the entrances were 131, with an aggregate tonnage of 9,807; clearances, 54, of 7,977 tons. On June 30, 1872, there were 524 vessels, of 27,537 tons, belonging to the district; engaged in the cod and mackerel fishery, 448, of 22,174 tons, of which 41, of 497 tons, were each less than 20 tons; built during the year, 18 vessels of 823 tons. The tonnage of the district on June 30, 1873, was 28,565; number of vessels (nearly all schooners), 517, of which 420 were employed in fishing, 90 in the coasting trade, 6 in foreign commerce, and 1 in yachting. A line of steamers from Glou-

cester runs daily to Boston. The manufactures are almost exclusively confined to articles pertaining to the fisheries, embracing anchors, ice crushers, bait mills, ships' blocks, masts and spars, boats, leads, fish guano, &c. There are six marine railways and 70 wharves. The extensive granite quarries on the N. side of the cape furnish stone which is mostly used for paving, but a considerable quantity is also prepared for other purposes. The new post office in Boston is built of Gloucester granite, and the base of the Scott monument in Washington, an immense block weighing nearly 100 tons, is of the same material. The city contains three national banks, with an aggregate capital of \$570,000, and three marine insurance companies. It is divided into eight wards, and is governed by a mayor, a board of aldermen of 8, and a common council of 24 members. There is a police court, an efficient police force, and a well organized fire department. The assessed value of property in 1873 was \$7,714,520; taxation, \$161,352; debt, \$218,000; value of property belonging to the city, \$830,785. It is lighted with gas. The principal charitable associations are the Gloucester fishermen's and seamen's widows' and orphans' aid society and the ladies' charitable society. There are 24 public schools, viz.: 1 high, 7 grammar, 12 primary, and 4 ungraded, attended by about 3,000 pupils, and supported at an annual cost of about \$40,000. Two weekly newspapers are published. The Sawyer free library contains about 4,000 volumes. The number of churches is 12, viz.: 2 Baptist, 2 Congregational, 1 Episcopal, 3 Methodist, 1 Roman Catholic, 1 Unitarian, and 2 Universalist. Besides these, there is a society of Swedenborgians who do not possess a church edifice.—The Indian name of Gloucester was Wingaersheek. It was occupied as a fishing station in 1624, being the first place settled by the English on the N. side of Massachusetts bay. In 1642 it was incorporated as a town under its present name, some of the principal inhabitants having come from Gloucester, England. The first schooner ever constructed was built here in 1713 by Capt. Andrew Robinson. The British sloop of war Falcon, Capt. Lindsay, assailed the town Aug. 8, 1775, bombarded it for several hours, and attempted to cut out some vessels in the harbor, but was driven off by the inhabitants. In

the second war with Great Britain, Sept. 8, 1814, Gloucester was attacked by the British frigate Tenedos, which, however, did no serious damage. In both of these wars the town sent out swarms of privateers, and contributed largely to the manning of the navy. It became a city in January, 1874.

**GLOUCESTER**, a city and municipal and parliamentary borough of England, one of the county towns of Gloucestershire, on the left bank of the Severn, 95 m. W. by N. of London; pop. in 1871, 18,330. The chief public edifice is the cathedral, originally the church of a Benedictine abbey. It was built and added to at various periods from the 11th to the 15th century, and is one of the most celebrated English cathedrals. It is remarkable for the perfection of the styles of architecture which indicate

Gloucester Cathedral, from the Southeast.

the different periods of erection and addition, and the choir is considered one of the finest examples of florid Gothic in the world. It contains many monuments, among others those of Robert, son of William the Conqueror, Edward II., Bishop Warburton, and Dr. Edward Jenner. The city also has several handsome parish churches, a college, blue-coat and free grammar schools, the county hall, hospitals, &c. The handsomest portion of the town is at the S. end, around a spring of saline chalybeate water discovered in 1814. The staple manufactures are pins, hardware, gloves, saddles, canvas, cutlery, ropes, and soap; and some ship building is carried on. A bell foundry was established prior to 1500, but it has recently been removed. Since the completion in 1827 of the Berkeley ship canal, by which vessels of 500 tons burden can come up to the city, the commercial importance of Gloucester has greatly

increased. The city is probably of British origin. It became a Roman station under the name of *Colonia Glevum*, and under Claudius received the name of *Claudia Castra*. The Saxons called it *Gleau-ceaster*, and it flourished during the heptarchy. In the 17th century it was strongly fortified, and took a conspicuous part against the royalists.\* The bishopric of Gloucester was instituted by Henry VIII., and was joined to Bristol in 1836.

**GLOUCESTERSHIRE**, a S. W. county of England, bordering on Worcestershire, Warwickshire, Oxfordshire, Berkshire, Wiltshire, Somersetshire, Monmouthshire, and Herefordshire; area, 1,258 sq. m.; pop. in 1871, 534,320. It is traversed from N. E. to S. W. by the Cotswold hills, which separate the basin of the Severn from that of the Thames. The district between these hills and the Severn comprises the vales of Evesham (principally in Worcestershire), Gloucester, and Berkeley, of surpassing beauty and richness. Beyond the Severn the greater part of the county is under forest, more than 20,000 acres of which still belong to the crown; it is called the forest of Dean, and was once the principal source of supply of timber for the English navy. The chief rivers are the Severn, Wye, Lower Avon, Frome, Thames, Colne, and Windrush. This county, having extensive and exceedingly rich natural pastures, has long been famous for its butter and cheese. The celebrated double and single Gloucester cheese is principally produced in the Berkeley vale. Large numbers of sheep are reared on the Cotswold hills and in the forest region, the latter being also noted for its orchards and the excellence of its cider and perry. Coal exists in great abundance; lead, sulphuret of iron, oxide of zinc, limestone, coral, quartz crystals, celebrated as Bristol diamonds, and gypsum, are also found. The manufactures are woollens, cottons, silks, hosiery, hats, tick, hardware, glass, paper, and carpets. Capitals, Gloucester and Bristol; other chief towns, Cheltenham, Cirencester, Stroud, and Tewkesbury.

**GLOVE**, a covering for the hand (sometimes extending up the arm), with a separate sheath for each finger. Gloves are spoken of by Homer as worn by *Laertes* to protect his hands while working in the garden. *Xenophon* speaks of *Cyrus* going without his gloves. The custom of giving a glove as a pledge in concluding a contract is very ancient, and from this is supposed to have been derived the later custom of throwing down a glove as a challenge, which the opposite party accepted by picking up the glove and throwing down his own. This is traced in England as far back as the year 1245. In the middle ages gloves were an object of special regard; they were made in the most costly manner, ornamented with precious stones, and worn by kings and church dignitaries on ceremonial occasions. A glove was used in the ceremony of bestowing lands and dignities, and deprivation of gloves was a sign of degradation. It was her glove which the

lady gave her faithful knight to wear in his helmet as a pledge of her favor. Down to the present time curious ceremonies have been associated with gloves, as the custom in some parts of Europe of taking them off when entering the stable of a prince or a great man, or else forfeiting them or their value to the servants. In hunting, the same ceremony must be performed under the same penalty at the death of the stag. Glove money is a term of ancient use, meaning money given to servants to buy gloves. Embroidered gloves were first made in England in 1580, and the custom of presenting them to judges at maiden assizes is still continued. Presenting a pair of gloves for any favor rendered is a very old custom.—Gloves are made of a variety of materials. In cold regions they are of the warmest wool, or of the skins of animals with the fur on the outside. Thick buckskin, often lined with soft woollen, is also used, but in more moderate climes lighter qualities of leather, to the softest kid, are employed, and also worsted, cotton, and silk. The preparations of caoutchouc are applied to the same purpose, chiefly for the protection of ladies' hands in rough work, such as gardening. The art of glove making is carried to its highest perfection in the manufacture of kid gloves by the French, being one of the most important industries of the country. The English, who make excellent gloves of heavier varieties of leather, largely import the best Parisian gloves. Woodstock and Worcester are celebrated for their fine leather glove manufactories, and kid and other gloves are also extensively made in London, Yeoville, Ludlow, and Leominster, generally, for the best qualities, of skins imported from France and Italy. Most of the cheaper kinds of so-called kid gloves are made from lamb, rat, and other thin skins. Sheepskin gloves, generally white, are made for the army. In 1871 England began to import opossum skins from Australia for glove making. Many first-class real kid gloves are manufactured in London, but they are generally sold as French. Great skill is required for the cutting of the skins to the best advantage; this process is performed with a pair of scissors after stretching and rubbing the skin upon a marble slab with a blunt knife. A skin is first cut longitudinally through the middle, and the single strip for the palm and back is next cut off from one end of the half skin. The pieces for the thumb, the gussets for the fingers, and other small pieces to be inserted, must all be worked out either from the same skin or from others precisely similar. The nearly square piece cut off is folded over upon itself, giving a little more width for the side designed for the back of the hand; and upon this oblong double strip the workman, measuring with his eye and finger, marks out the length for the clefts between the fingers, which he proceeds to cut and shape. Making the hole for the thumb requires the greatest skill, for a very slight deviation from

the exact shape would cause a bad fit when the parts are sewed together, resulting in unequal strain and speedy fracture. By improvements introduced by M. Jouvin, the thumb piece, like the fingers, is of the same piece with the rest of the glove, requiring no seam for its attachment. The cutting also is performed in great part by punches of appropriate patterns, and some of these are provided with a toothed apparatus somewhat resembling a comb, which pricks the points for the stitches. The seams are sewed with perfect regularity by placing the edges to be united in the jaws of a vice, which terminate in fine brass teeth like those of a comb, but only  $\frac{1}{12}$  of an inch long. Between these the needle is passed in successive stitches. When the sewing is completed the gloves are stretched, then placed in linen cloth, slightly damp, and beaten, by which they are rendered softer and more flexible. The last operation is pressing. In 1866, while England exported 680,664 pairs of leather gloves of British make, it imported 10,619,220 pairs, of which 10,036,092 were from France. In the same year England exported 315,180 pairs of cotton gloves, chiefly to the United States. But in 1868 Germany was not only competing with England in leather gloves in the London market, but it sent three fourths of the cotton and Lisle thread gloves sold in England, and for export had secured nearly the entire trade of the United States, which had formerly bought this class of goods in Nottingham and Leicester. In 1868 the value of gloves made in France was estimated at 50,000,000 francs, and the manufacture was increasing.—The chief branch of the manufacture carried on in the United States is that of buckskin gloves, a kind more peculiarly American than any other; and the most important seat of this business is at Gloversville, Fulton co., N. Y. Kid gloves are now made to some extent there and in New York.

**GLOVER, Richard**, an English poet and politician, born in London in 1712, died there, Nov. 25, 1785. He was educated for a mercantile life, but early manifested a love of letters, and at the age of 16 wrote a poem to the memory of Sir Isaac Newton. In 1737 he published an epic on the Persian invasion of Greece, entitled "Leonidas," which was thought to have an application to English politics, and was for a time much admired. A continuation of it, under the title of the "Atheniad," appeared in 1787. His "London, or the Progress of Commerce," and a ballad called "Hosier's Ghost" (1739), were written to rouse his countrymen to a war with Spain. He was active in politics as an opponent of Walpole, and was returned to parliament for Weymouth in 1760. He wrote several tragedies, and a diary which was published in 1813, and in the following year appeared an "Inquiry" attempting to prove that he was the author of the letters of Junius.

**GLOVERSVILLE**, a village in the town of Johnstown, Fulton co., New York, 40 m. N. W. of Albany, at the terminus of the Fonda, Johns-

town, and Gloversville railroad, which connects with the New York Central at Fonda, 7 m. distant; pop. in 1870, 4,518. It is chiefly noted for its extensive manufactures of gloves and mittens. The business was commenced in 1803, and the village now contains about 140 establishments, manufacturing two thirds of the kid and buckskin gloves and mittens made in the United States. There are also manufactories of machine and glove patterns, organs, railroad lamps, carriages, kid and other leather, a planing mill, two national banks, three weekly newspapers, and seven churches.

**GLOWWORM**, a name given to several serri-corn beetles, constituting the genus *lampyris* (Fab.). The antennæ are short, with cylindrical and compressed articulations; the head is concealed beneath the anterior margin of the thorax; the eyes and the mouth are small; the body is rather soft and depressed, with the sides of the abdomen serrated; the elytra are coriaceous and slightly flexible. The females are wingless, with rudiments of elytra at the base of the abdomen, and their general appearance to the uneducated eye is that of a worm, explaining fully the popular name of glow-

Glowworm (*Lampyris splendidula*).  
1. Male. 2. Female. 3. Larva of *L. noctiluca*.

worm in England, and *ver luisant* in France. In the old Linnæan genus *lampyris* there were as many as 60 species, which have been distributed into different genera, so that there were only nine species left in the genus in the last edition of Dejean's catalogue. There are four well known species of glowworm in Europe, *L. noctiluca*, *Italica*, *splendidula*, and *hemiptera*; the second is probably the species whose luminous faculty was known to the ancients, the *λαμπροφίς* of the Greeks, and *cicindela* of the Romans. Both sexes are luminous, though the light is stronger in the female; the light does not come from the thorax as in the fire-fly (*elater*), but from the posterior part of the abdomen on its upper and under surfaces. The English glowworm (*L. noctiluca*, Linn.) is the largest European species, about two thirds of an inch long in the male, and the female about an inch; the male is brownish gray, with a reddish gray margin on the superior portion of the thorax, and has both wings and elytra; the female is wingless, of a uniform yellow white, with a very thin skin below; in both sexes the luminous spots show themselves as

four bright points, two on the antepenultimate abdominal segment, and two on the next posterior. The *L. Italiae* is next in size, and is found in southern Europe, as the first is in the northern countries; the color is black, with red prothorax and legs; both sexes are winged, and much resemble each other, the apterous females spoken of by some entomologists being the larvæ. The *L. splendidula* is common in Germany; the male is winged, brown gray, with a bright glassy spot on the convex margin of the prothorax; the female, whitish yellow with a brown spot on the centre of the prothorax, has no wings, and very short oval elytra; the luminous spots are two transverse bands on the lower surface of the two penultimate abdominal segments, and in the female the whole abdomen diffuses a weak light. *L. hemiptera*, a southern species, and the smallest one third of an inch long, is opaque black, lighter in the female, the posterior ventral plates being whitish; the males have truncated elytra, the females none; the light is diffused from two round spots on the penultimate segment; the larvæ are probably luminous, as those of the preceding species were found to be by Burmeister. The first three species conceal

Glowworm (*Lampyris noctiluca*).

themselves in the daytime and appear at night, the males flying about in the warm summer evenings, while the females betray their situations by their tranquil light among the shrubs; the last species creeps also by day, especially in damp weather, appearing toward the end of April; the third species occurs about the end of May and the beginning of June, while the first is found most abundantly toward the end of summer. The light is greenish or more commonly bluish white, intermittent or continuous at the will of the insect, extinguished in time of danger, and increased by active motion, sexual excitement, or artificial heat; it may continue some hours after death, and when lost may be reproduced by warm water; poisonous gases destroy the light with life, while oxygen increases its brilliancy; electricity produces no effect on the light, while galvanism increases or reproduces it in dead insects. The researches of Kölliker and others show that at the shining spots is a whitish, transparent, fatty mass, permeated by very numerous tracheæ; this mass will shine when removed from the body, and in warm water for a long time, and its particles rubbed upon the fingers display a light

resembling that from phosphorized mixtures. The eggs of the glowworm, the larvæ, and the nymphs, are luminous; the eggs are hatched after a few weeks, and the larvæ resemble the perfect females, having a body of twelve segments, the first three of which bear each a pair of feet; the head is small, and, like the caudal segments, retractile; they thrive well in captivity when kept in moist earth or herbage, and supplied with slugs and snails, which they kill with their arched and sharp-pointed jaws, and eagerly devour; about a week is occupied in assuming the state of nymph, and in about eight days longer they appear as perfect insects. The nymph is larger than the larva, but not quite so long; the color is at first pale yellow, with two reddish spots on the posterior part of the thorax and the segments, but the dull color of the perfect insect is visible toward the end of the nymph state; the larval jaws disappear, and the antennæ are seen to have eleven joints, and the tarsi five; the last abdominal rings are very brilliant, and indeed the whole body seems phosphorescent. According to Dufour, the alimentary canal of the perfect female is twice as long as the body, and the œsophagus exceedingly short, immediately dilating into a short crop.—The substance from which the luminous property is derived has been often made the subject of experiment, but as yet, according to Matteucci, without the detection of any phosphorus in it, though the circumstances attending the light resemble the conditions under which phosphorus is luminous, being increased by warmth, diminished by cold, and destroyed by irrespirable gases, oil, alcohol, acids, and strong saline solutions; these phenomena admit of a better explanation on Matteucci's theory. This author, in his *Leçons sur les phénomènes physiques des corps vivants*, explains all cases of animal phosphorescence on physico-chemical principles. From his experiments we know that the light of the glowworm may cease before the death of the animal, or may be considerably prolonged after this event; that the light is without heat, as far as our rude instruments can detect; that it ceases soonest in carbonic acid, and in hydrogen in from 30 to 40 minutes; that it is increased in oxygen, and lasts three times as long as in other gases, both for parts and for the entire insect; that it consumes a portion of oxygen, which is replaced by carbonic acid, and is therefore the product of a true combustion; that when not shining, and in contact with oxygen, none of this gas is taken up, and no carbonic acid is formed; that heat to a certain extent increases, while cold diminishes its brightness; that when the luminous substance has been altered by too great heat or the action of gases so as to lose its phosphorescence, this property cannot be reestablished; finally, that carbon and not phosphorus is one of the elements of this substance, and that the phosphorescence is produced by the combination of the carbon with the oxygen. The luminous matter from the living insect,

according to the same author, has a peculiar odor resembling that of the perspiration of the feet; it is neither acid nor alkaline, dries rapidly in the air, seems to coagulate in contact with dilute acids, is not sensibly soluble in alcohol, ether, or weak alkaline solutions, but is dissolved in concentrated sulphuric and hydrochloric acids with the aid of heat; chemical tests exclude the idea of the presence of albumen, and the ordinary ammoniacal products are disengaged by heat. The oxygen of the atmosphere introduced by the numerous tracheæ comes in contact with this substance, *sui generis*, composed principally of carbon, hydrogen, oxygen, and nitrogen. The intermittence of the glowworm's light, and its sudden changes from darkness to brightness, as far as present investigations go, are dependent on the different amounts of air introduced into the tracheæ, and the varying activity of respiration and muscular action. The change in the food of the glowworm, from animal juices in the larva state to tender plants in the perfect condition, explains the contradictory statements of authors as to the habits of this insect; and the failure of the attempts to introduce it as an ornament to shrubberies and lawns has generally arisen from ignorance of the fact that the larva cannot be raised on vegetable food alone; besides moist herbage or damp earth, minute land shells must be supplied.—A few specimens of an articulated animal which may be called a glowworm have been found of late years in summer in various parts of southern New England. The head is small and flat, with very short antennæ; the color is cream-white, the length about 14 lines, and the whole of this is lighted up at night with a permanent luminousness less than that of the elaters of the West Indies; the light begins to show itself between the segments, of which there are 12, and at the stigmata, from which it spreads until the whole animal is illuminated, seeming a stick of light without joints or stigmata; most brilliant soon after midnight, they gradually fade to the ordinary whitish color at day-break.—In all these cases of phosphorescent articulates it is difficult to say what is the precise purpose of the light. (See FIREFLY.)

**GLUCINA** (Gr. γλυκός, sweet), an earth, first obtained by Vauquelin in 1798, consisting, according to Berzelius, of two atoms of the metal glucinum, united with three atoms of oxygen; but Awdejew and others regard it as a protoxide, GIO. It is found only in a few minerals, as the emerald, beryl, euclase, &c., being contained in the first two in the proportion of  $13\frac{2}{3}$  per cent., combined with silicic acid. It is obtained in the form of a white powder, of specific gravity about 3, closely resembling alumina. It is distinguished by its solubility, when freshly prepared in a cold solution of carbonate of ammonia, and by its tendency to form a carbonate by exposure to the air; also by not giving a blue color in the blowpipe test with nitrate of cobalt. The properties of glucinum, the

metallic base of glucina, have been investigated by Debray (*Annales de chimie et de physique* [3], xlv. 5), who obtained it from the chloride by reduction with sodium, the original source being the emerald of Limoges. He found it a white malleable metal, that could be rolled in sheets like gold, of density 2.1, its melting point below that of silver. It cannot be made to burn in pure oxygen, but appears in the trial to be slightly oxidized on the surface, by which it is protected from further change. It resists the action of sulphur, but combines with chlorine and iodine. Its alloy with silicium is a hard brittle substance, susceptible of a high polish. Glucinum is soluble in sulphuric and in hydrochloric acids, hydrogen being evolved. Nitric acid acts upon it only when heated, and then slowly. It dissolves in caustic potash. Its symbol is G; chemical equivalent, 9.2.

**GLUCK, Christoph Wilibald von**, a German composer, born at Weidenwang in the Upper Palatinate, July 2, 1714, died in Vienna, Nov. 15, 1787. The dates and other particulars in this article which differ from those usually given, are drawn from documentary evidence substantiated or first given to the public by Anton Schmid, of the imperial library at Vienna, in 1854 (*Glucks Leben und tonkünstlerisches Wirken*). The father, Alexander Johannes Klukh (as he always wrote his name), was first a huntsman of Prince Eugene, afterward removing to Weidenwang as forester. In 1717 he entered the service of Count Kaunitz in Bohemia, and thus the young Christoph came at the age of three to the land which, owing to its great number of wealthy nobles and convents, was then the most favorable to the development of musical talent. In the gymnasias and the Jesuit colleges music was earnestly cultivated, and every nobleman had his musical chapel; all churches of any pretensions, very many of the smaller parish churches even, had their choirs supported by ample funds. The treatment of Gluck and his brothers by the father was hard even to tyranny; the composer in his old age well remembered being forced with his brother Anton to follow his father in the coldest winter weather into the forests, sometimes barefoot, "to make them tough." The children had the best school instruction in Kamnitz and Eisenberg, and from his 12th to his 18th year Christoph was sent to the gymnasium at Kommotau. The boy carried with him a good degree of knowledge both in singing and playing bowed instruments, and in the school of the Jesuits his musical talents were specially cultivated. He became a chorister in the principal church of the place, and gained some knowledge of the harpsichord and organ. At 18 he went to Prague to enter the university, but was finally obliged to devote himself to music for subsistence. He gave lessons in singing and upon the violoncello, sang and played in several churches for a small salary, and during vacation sang and played in the villages of the surrounding country, sometimes

being paid in one with eggs, which in another he exchanged for bread. After a time he appeared in the large towns as a violoncellist, and attracted the attention of Prince Lobkowitz, so that when in 1736 he went to Vienna, the house of the prince was opened to him, and a salary was given which enabled him, at 22, to study musical science. He now had opportunity also to hear the works of Fux, Caldara, the brothers Conti, Porsile, and other dramatic and church composers, adequately performed. The Lombard prince di Melzi, hearing Gluck both as a singer and violinist, in the soirées of Lobkowitz, appointed him chamber musician, took him to Milan, and placed him under Sammartini. Having meanwhile shown talent in composition, in 1740 he received an order to compose an opera for the court theatre of Milan. The old field of the Italian opera of Handel's time had now been nearly exhausted, and the works of the day, even those of the greatest masters, had gone down in the scale until they were little more than pieces of music written to give the singers opportunity to exhibit their powers. Real musical expression was one of the last things which entered into the thoughts of the composer. Hence the first work of Gluck has an importance in musical history beyond any other of that time, unless the oratorios of Handel be excepted. The text chosen for him was the *Artaserse* of Metastasio, a libretto which in its form was sufficient—in case Gluck had then, which he had not, thought out the system which he afterward adopted and which produced an entire revolution in the musical drama—to prevent him from striking out an entirely new path. Still the composer had an indistinct feeling of the hollowness and insufficiency of the recognized forms of dramatic composition, and ventured to make expression the great object of his music. He completed the work, with the exception of one air, in his own manner, and in 1741 had it in study. At the first rehearsal in the theatre a large company was present. The new work proved so different from what they were accustomed to hear as to be generally received with smiles, and shrugs, and jokes upon the German composer. Gluck let all pass without remark. For the final rehearsal he composed the wanting air in the strictest style of the day. It was a beautiful piece for the singer, and when the audience heard it they broke into the loudest applause, and with one consent attributed it to Sammartini. Gluck remained silent. The first public performance came off with appropriate scenery and action. The house was crowded. The interest rose with every number, the music meeting with the most decided success, until the modish air, which proved so "stale, flat, and unprofitable," so out of character with all the rest, that Gluck had to withdraw it and substitute one more in the spirit of his work. The success was triumphant, and the composer was called from city to city of Italy to direct

the *Artaserse*. He was now the great operatic composer of that era. In 1742 he wrote *Demofoonte*, text by Metastasio, for Milan; *Demetrio* and *Ipermestra*, texts by the same, for Venice; in 1743, *Artamene* for Cremona, and *Siface* for Milan; in 1744, *Fedra* for Milan; in 1745, *Alessandro nell' Indie*, by Metastasio, under the title *Poro*, for Turin. Lord Middlessex invited him to London to compose for the theatre in the Haymarket, and in 1745 he set out for the English capital, but found the theatre closed. On Jan. 7, 1746, it was reopened, with *La caduta de' giganti*, by Gluck. It was not successful, and was only performed five times. He afterward produced *Artamene* with better fortune, and *Piramo e Tisbe*, in which pieces from his earlier works were, at the wish of the managers, adapted to a new text. This failed comparatively; and this event led Gluck to his permanent system of composition, whose principles are as follows: 1, that dramatic music can only reach its highest power and beauty when joined to a text simple, truly poetic, and exhibiting natural and definite emotions and passions with the highest possible truth to nature; 2, that music might be made the language of emotion, capable of expressing the various feelings of the heart; 3, that the music must follow with all possible exactness the rhythm and melody of the words; 4, that in accompaniments the instruments must be used to strengthen the expression of the vocal parts by their peculiar characters, or to heighten the general dramatic effect by employing them in contrast to the voice, as the text or dramatic situation might demand. From these principles it followed that the beautiful arias then esteemed the highest efforts of the musical art, though in fact unsurpassable as means of sensual gratification to the ear, could never deeply touch the soul nor rouse any lasting emotion. In his later years Gluck was in the habit of saying, when an air of this kind was commended: "Yes, it is right beautiful; but it does not draw blood." Toward the close of 1746 the composer returned to Germany. Dlavacz says he became a member of the electoral orchestra of Dresden with a respectable salary, which seems probable, but in fact none of the biographers have cleared up the chronology of his life for the two or three years after his return. On June 29, 1747, an opera in one act, *Le nozze d'Ercole e d'Ebe*, music by Gluck, was performed at Pilnitz in honor of the marriage of Princess Anna, daughter of Augustus III. According to Schmid, *La Semiramide riconosciuta*, text by Metastasio, music by Gluck, was performed at Vienna on Maria Theresa's birthday, in May, 1748; and in the autumn of the same year a newspaper contains a paragraph of news from Hamburg, which is dated Oct. 3, and says: "Herr Gluck, so well known in music, is at present chapelmaster here in place of Scalabrini." In 1749 he removed to Vienna, and only left that city when called to Italy and Paris to produce his works. In the

house of Joseph Pergin, a banker and wholesale merchant, he was received both as a friend and as music teacher of the two daughters. With Marianne he fell in love, and his passion was returned. The mother approved the match, but when the young man applied to the father for the hand of his daughter, he was rudely refused, as being but a musician. Wounded by this, Gluck now accepted an order to compose *Telemacco* for the theatre Argentina at Rome, and left Vienna at once, in such haste to be away that, without waiting for his passport, he smuggled himself across the boundary in the habit of a Capuchin monk. In 1750 news came to him that Pergin was dead. As soon as his opera was upon the stage, where, like all his other works, it was successful, he hastened back to Vienna, and on Sept. 15 was married. The marriage was childless, but few have been happier, and seldom even during his most tedious journeys were Gluck and his wife separated. In 1751 he visited Naples, to produce *La clemenza di Tito*; in 1754 he composed *Le Cinesi*, a fantastic production, performed at Schlosshof before the emperor and Maria Theresa; and the same year he was appointed chapelmaster of the imperial opera at Vienna, which office he held until 1764. Before the close of the year he was again called to Rome, and produced there *Il trionfo di Camillo* and *Antigono*, which gained him from the pope the order of knight of the golden spur; hence his title in musical history, Chevalier or Ritter. In 1755 he produced the music to Metastasio's *La danza*; in 1756, *L'innocenza giustificata* in one act, and *Il re pastore* in three. Between 1755 and 1762 he composed also a great number of airs and other pieces for a series of ten French operettas and vaudevilles performed in Vienna. In 1760 his principal work was *Tetide*, a serenata composed for the nuptials of the archduke Joseph; and in 1761 a most successful ballet, *Don Juan*, or *Das steinerne Gastmahl*, founded upon the same fable afterward employed by Da Ponte in his text to Mozart's immortal opera. In 1762 *Il trionfo di Clelia* was composed at Bologna, and met with the invariable success of Gluck's productions, and then its author returned to Vienna. Calzabigi had there ready for him the libretto of *Orfeo ed Euridice*, a poem differing completely in construction from the Metastasian type, which then alone was recognized as classic throughout Europe. Orpheus, Eurydice, and, in two or three short scenes, Amor are the only characters represented. At the beginning and end a chorus of Greeks, in Tartarus a chorus of shades and demons, in Elysium a chorus of blest spirits, each occupying a single scene, with choral music and ballet, is all that divides the attention from the three leading characters. The subject, opening with a chorus at the tomb lamenting the death of Eurydice, is the familiar myth, only changed at the close, where Amor appears and finally restores the beloved one to Orpheus. There is

but little action, and that of the simplest character. Everything depended upon exciting the sympathies of the audience at the outset, and holding them to the end, and this too by musical means then new and strange. Twice in this work Gluck has shown the daring of genius trusting to its own powers, in a manner not surpassed by Beethoven himself. At the close of the first chorus Orpheus dismisses his friends, and is left alone not merely to execute a recitative and single air, written expressly for the singer to exhibit his powers, but a series of them, in which not an ornament or cadenza is admitted, and which nothing but the depths of expression in Gluck's music could redeem even now from the fatal fault of tedium. The other case is that in which Orpheus entering Tartarus is confronted by demons and shades, who by the force of his music at length are led to give way and allow him to pass on to Elysium. On Oct. 5, 1762, the opera was performed in public. Surprise and astonishment were the emotions with which the audience left the house. All hearts had been strangely moved. It had interested the company from the first singer to the most insignificant dancer in the ballet, and was given with rare perfection. The music made its way to all hearts, it became a most popular work in Vienna, and is still a stock piece in Berlin. In 1763-'5 Gluck composed *Enzio*, text by Metastasio; *La rencontre imprévue*, text by L. H. Dancovot (afterward very popular in a German translation with the title *Die Pilgrime von Mekka*); and *Il Parnasso confuso*, a dramatic poem by Metastasio, performed in the palace at Schönbrunn by the four daughters of Maria Theresa, sisters of Marie Antoinette, their brother, the future emperor Joseph, playing the harpsichord; revised *Telemacco* for the Vienna stage, and composed *La corona* for the archduchesses. The last piece was never performed, owing to the sudden death of the emperor Francis. The dramatic form of none of these works, although they gave Gluck opportunity to prove his inexhaustible fund of melodic and harmonic beauty, enabled him to follow the path struck out in the *Orfeo*. In the mean time Calzabigi prepared another libretto for him, founded upon the "Alcestis" of Euripides, and it was successful. In 1769 it was printed in score, with the celebrated dedicatory epistle to the grand duke of Tuscany. "When I undertook to set the opera *Alceste* to music," he writes, "I purposed carefully to avoid all those abuses which the mistaken vanity of the singers, and the too great good nature of composers, had introduced into the Italian opera; abuses which reduced one of the noblest and most beautiful forms of the drama to the most tedious and ridiculous. I sought therefore to bring back music to its true sphere, that is, to add to the force of the poetry, to strengthen the expression of the emotions and the interest of the situations, without interrupting the action or deforming the music by useless ornamentation. I was of opinion that

the music must be to the poetry what liveliness of color and a happy mixture of light and shade are for a faultless and well arranged drawing, which serve only to add life to the figures without injuring the outlines. I have therefore taken care not to interrupt the actor in the fire of his dialogue, and compel him to wait for the performance of some long tedious *ritornello*, or in the midst of a phrase suddenly hold him fast at some favorable vowel sound, that he may have opportunity by some long passage to exhibit his voice, or to make him wait while the orchestra gives him time to get breath for some long *fermate*. Nor have I thought myself at liberty to hurry over the second part of an aria, when perhaps this is just the most passionate and important part of the text, and this only to allow the customary repetition of the words four times; and just as little have I allowed myself to bring the aria to an end where there was no pause in the sense, just to gain an opportunity for the singer to show his skill in varying a passage. Enough; I wished to banish all those abuses against which sound common sense and true taste have so long contended in vain. I am of opinion that the overture should prepare the auditors for the character of the action which is to be presented, and hint at the progress of the same; that the instruments must be ever employed in proportion only to the degree of interest and passion; and the composer should avoid too marked a disparity in the dialogue between air and recitative, in order not to break the sense of a period, or interrupt in a wrong place the energy of the action. Further, I considered myself bound to devote a great share of my pains to the attainment of a noble simplicity; therefore I also avoided an ostentatious heaping up of difficulties at the expense of clearness; I have not valued in the least a new thought if it was not awakened by the situation and did not give the proper expression. Finally, I have even felt compelled to sacrifice rules to the improvement of the effect." In 1769 Gluck produced a third opera in the new style, *Paride ed Elena*, but it became popular only with musicians, and has in late years never been revived. In that year he was called to Parma to compose festival music for the marriage of the grand duke to Maria Amalia, daughter of Maria Theresa. Instead of a long opera, divided into acts, four short one-act pieces were prepared, *Le feste di Apollo*, *L'Atto di Bauco e Filemone*, *L'Atto d'Aristeo*, and for the fourth the *Orfeo* given in seven scenes, with the greatest success. For several years afterward he remained in Vienna, enjoying great social distinction, but composing nothing for the stage. His next great effort was the *Iphigénie en Aulide*, which after many struggles and the removal of innumerable obstacles was finally, through the influence of Marie Antoinette, produced on April 19, 1774, at the royal opera in Paris, whither Gluck had gone in the previous summer. It was followed by an embittered warfare between the adhe-

rents of the old school, then chiefly represented at Paris by Piccini, and the converts to the new ideas of Gluck. A catalogue of the writings of the Gluckists and Piccinists on the two sides of this question would fill one of our pages. The final result was the complete victory of Gluck. The composer followed up the *Iphigénie* with the *Orfeo ed Euridice*, adapted to the French stage, with the very material alteration of changing the part of Orpheus to that of a tenor, to suit the voice of Legros, there being no contralto adequate to it. The success of the work was as striking in Paris as in Vienna and Turin. In February, 1775, Gluck produced *L'Arbre enchanté*, in one act, at Versailles, a work of no great importance, and written merely for a festival given by Marie Antoinette to her young brother Maximilian. In August his *Cythère assiégée* was produced at the academy, but met with no distinguished success. Meantime he was zealously engaged upon three works, an adaptation of *Alceste* to the Prussian stage, and the operas *Roland* and *Armide*, texts by Quinault. *Roland* he laid aside on hearing that it had also been intrusted to Piccini, and wrote a sharp letter to Bailly du Rollet, which, without the consent of the writer, was printed in the *Année littéraire*, and enraged the Piccinists. Early in 1776 Gluck was again in Paris with his *Alceste*. It was produced, and hissed off the stage. The unlucky composer, who had been behind the scenes, rushed from the opera house, and meeting a friend threw himself into his arms in tears. As this ill success was mostly owing to cabals among the singers and the personal efforts of Gluck's opponents, and as the composer had influence enough to insure its repetition, it made its way with the public, and soon took its place only below the *Iphigénie* and the *Orfeo*. The war of the wits and critics was, however, more bitter than ever. Gluck himself seems to have been not a little embittered, and his polemical writings are often excessively keen. In the midst of his ill success with the *Alceste* came the news that his niece Marianne, whose ill health had caused him this time to visit Paris alone, had been carried off at the age of 16 with the smallpox. Upon her the childless musician had lavished all a father's love. She had been a pupil of Millico, and when but a child, as Burney records, was already a songstress of wonderful powers. It was not until Sept. 23, 1777, that the *Armide*, text by Quinault, from Tasso, was produced. It was rather coldly received, but is by many considered the greatest composition of Gluck, and by others only inferior to his later work, the *Iphigénie en Tauride*. Gluck returned to Vienna to work upon a new text, *Iphigénie en Tauride*, by a young poet named Guilbard. In November, 1778, he was so far advanced with it that he returned to Paris, where on May 18, 1779, it was produced. Like Haydn's "Creation," written when he was nearly 70 years of age, this opera of Gluck, written at

the age of 64, ranks among the highest efforts of the composer; with many, as before stated, it ranks the first. It is still, in a German translation, one of the favorite pieces on the Berlin stage. It was the crowning triumph of Gluck's system of operatic writing, and ended the series of works which gave direction to the genius of Mehul and Cherubini in Paris, Mozart and Beethoven in Germany, in their works for the stage. Another piece brought by Gluck to Paris at this time, the *Écho et Narcisse*, met with no great success. He returned to Vienna, and in 1783 had an attack of apoplexy, which caused him to decline the text of *Les Danaïdes*, sent him from Paris. To his dramatic compositions Gluck added only for the church a *De Profundis*, a psalm, *Domine Dominus noster*, and a part of the sacred cantata, finished by Salieri, *Le jugement dernier*. For months before his decease, Gluck had been obliged to use the greatest precautions to prevent a return of apoplexy. One day he invited two old Parisian friends to dine with him. After the meal, coffee and spirits were placed upon the table, and Mme. Gluck went out to order the carriage for the daily drive prescribed by the physician. One of the friends excusing himself from emptying his glass, the host at last seized it, swallowed its contents, and laughingly told them not to let his wife know of it, as everything of the kind was forbidden to him. The coach being ready, Mme. Gluck invited the guests to amuse themselves in the garden for a short time. Gluck took leave of them at the coach door. Fifteen minutes afterward he had another stroke; the coachman hurried home; his master had already lost all consciousness, and soon breathed his last.—See *Gluck et Piccine*, by Gustave Desnoiresterres (Paris, 1872).

**GLÜCKSTADT**, a town of Prussia, in the province of Schleswig-Holstein, on the right bank of the Elbe, 27 m. N. W. of Altona; pop. in 1871, 5,073. The inhabitants are chiefly engaged in commerce and the whale fishery. The town was fortified in 1620 by Christian IV. It was unsuccessfully attacked by Wallenstein in 1627, by Tilly in 1628, by Torstenson in 1644, and yielded to the allies in 1814. The fortifications were demolished in 1815, and it was declared a free town in 1830. It passed into the possession of Prussia in 1866. The town has a gymnasium, and is connected by rail with Altona, Kiel, and Rendsburg. The royal line of the dukes of Holstein assumed the name of Holstein-Glückstadt, while the ducal line bore that of Holstein-Gottorp.

**GLUCOSE**. See supplement.

**GLUE** (Lat. *gluere*, to draw together), an impure variety of gelatine, used in the arts for uniting substances through its adhesive quality. It is obtained much in the same manner from the same substances as gelatine, but usually from the more refuse portions, as damaged hides and other tissues undergoing putrefaction. Glue obtained from bones by the use of acids is preferred to that which is obtained by steam,

the latter being more soluble in cold water. The strongest glue is made from the parings of ox hides, which yield over 50 per cent. They are steeped for several days in milk of lime to remove the hair, blood, and other impurities; then washed in cold water, drained on an inclined plane, and again washed. Exposure to the air converts the lime into carbonate, so that in boiling the caustic action of the lime is prevented. The material is then enclosed in a coarse cloth and put into a copper boiler, which is two thirds filled with rain water, and the whole is boiled. The dissolved glue mingles with the water outside of the cloth, and when the liquid sets into a firm jelly on cooling it is run into a deep vessel or settling back and kept warm for impurities to subside. Water is again added to the boiler, and the material in the cloth subjected to a second boiling, by which an inferior glue is obtained. The liquid in the settling back is drawn into coolers, where it solidifies, and is then cut into slices with a wire frame. The slices are laid upon netting in a drying room, in which there is a free circulation of air. The operation of drying is a critical one. Too much heat will cause liquefaction; a fog may cause mouldiness, and frost will split the slices. Good glue is of a pale brown color, hard and brittle, and breaks with a glassy fracture. Its other chemical and physical properties are like those of gelatine. The quality of glue may be judged of by the quantity of water which the dry glue will absorb in 24 hours. The best glue kept immersed in water of the temperature of 60° F. has absorbed 12 times its weight. Other qualities, it is said, take up a proportionally less quantity. Besides its use for cementing wood and hard substances, glue is employed in preparing the felt bodies of hats, and as an ingredient in the composition of inking rollers, to give them flexibility.—Several varieties of glue are employed in the arts, some of which may properly be noticed here, although they are not all preparations of gelatine. If glue is treated with a small proportion of nitric acid, it loses its property of gelatinizing when cold, though not that of causing substances to adhere together. With acetic acid a similar effect is produced. What is called liquid glue is made by slowly adding nitric acid to the ordinary preparation of glue in the proportion of 10 oz. of strong acid to 2 lbs. of dry glue dissolved in a quart of water. The product is a strong glue, which remains in a liquid state, and may be thus kept for years always ready for use. Marine glue is a preparation of caoutchouc dissolved in naphtha or oil of turpentine, with the addition of shell lac after the solution has by standing several days acquired the consistency of cream; two or three parts by weight of shell lac are used for one of the solution. The composition is then heated and run into plates, and when used it is heated to the temperature of about 250° F. It possesses extraordinary adhesive properties, and being

quite insoluble in water, it has been recommended as a material for fastening together the timbers of ships; so securely are these held by its application that it is said they will sooner break across the fibres than separate at the joint.

**GLUKHOV**, a town of Russia, in the government and 108 m. E. by N. of the city of Tchernigov, on the Yesmana; pop. in 1867, 10,747. It has eight churches and several schools, and was formerly the seat of the governor general of Little Russia.

**GLUTEN**, or **Vegetable Fibrine**, a tough elastic substance, named from its adhesive glue-like property, an ingredient in wheat especially, and in smaller proportion in most of the cerealia and in some leguminous plants. When wheat flour is well kneaded upon a sieve under a stream of water, the starch is removed in suspension in the water, and the soluble dextrine and sugar are washed away, and the gluten remains behind. This was supposed by Beccaria, who first noticed it, to be a distinct principle; but it is found still to retain a little starch, and other ingredients are separated from it according to their different reactions when treated with boiling alcohol. The pure vegetable fibrine is then found to constitute about 72 per cent. of the original gluten, while an albuminous substance called gliadine, vegetable caseine, and a vegetable oil make up the remainder. Gluten from rye flour contains very little of the tenacious ingredient, gliadine; and other grains furnish gluten of variable proportions of its ingredients. It is gluten which gives to the dough of wheat flour its peculiar tenacity, and it is owing to this that the escape of carbonic acid gas is arrested in the fermentation of wheat bread, and the product is consequently lighter and more spongy than other bread. Macaroni and vermicelli are preparations of gluten, and the flour of the south of Europe is said to be peculiarly adapted for this manufacture, as it generally contains a considerably larger proportion of gluten than that grown further north. But the proportion is variable in wheat of the same vicinity, and it may be increased by the use of animal manures, especially those richest in nitrogen. Liebig noticed that wheat manured with cow dung (which contains but little nitrogen) produced 11.95 per cent. of gluten; while another portion manured with human urine yielded the maximum of gluten, 35.1 per cent. Summer wheat grown in the *jardin des plantes* at Paris was found to contain 26.7 per cent. of gluten, while a sample of winter wheat gave but 3.33 per cent. As gluten is the most nutritious ingredient in the grains, its proportion has been carefully estimated by chemists. Vauquelin found it in wheat averaging 11.18 per cent.; Dumas 12.50 per cent.; and Dr. Lewis C. Beck, from 33 samples gathered from different parts of the United States, found an average of 11.72, the range being from 9.85 to 15.25 per cent. Prof. Horsford, by ultimate analysis of the wheat, in-

stead of separation of the gluten by mechanical washing, obtained an average of 15.14 per cent. from six samples. Payen found the proportions of gluten and other nitrogenous matters in wheat to range from 11.20 to 22.75 per cent.; in rye, 13.15; barley, 13.96; oats, 14.39; corn meal, 12.50; rice, 7.05. Prof. Johnston found in English fine wheat flour 10, in bran of the same flour 18, in Scotch oatmeal 18, and in corn meal 12 per cent. of gluten. It is found by very careful and repeated analyses that the bran of wheat and of most other cereals is richer in gluten, and consequently more nutritious, than the rest of the grain. Hence the preference for flour that by thorough bolting has been most completely deprived of bran is unwise; and the whitest flour is less valuable for its nutritive qualities than that made from the whole grain. The bran sometimes constitutes one quarter or more of the grain, and, according to the analyses of Prof. Johnston, contains 14 to 18 per cent. of gluten, while the fine flour contains only 10 per cent. Gluten is readily reduced in quantity, and its tenacity is diminished by injury to the grain. Flour dealers and bakers judge of the quality of flour by the tenacity of the dough made from a few grains of it.—The subject is further treated under ALIMENT.

**GLUTTON**, a carnivorous mammal, belonging to the family *mustelida*, subfamily *martinae*, and genus *gulo* (Storr). The dental formula is that of the true martens, viz.: incisors  $\frac{3}{1}-\frac{3}{1}$ , canines  $\frac{1}{1}-\frac{1}{1}$ , premolars  $\frac{4}{2}-\frac{4}{2}$ , molars  $\frac{1}{1}-\frac{1}{1}=\frac{1}{1}$ , in all 38; the first three molars in the upper and the first four in the lower jaw are small, succeeded by a larger carnivorous tooth. In dentition and general structure the glutton resembles the

Glutton or Wolverine (*Gulo luscus*).

martens; but in its shape, and partially plantigrade feet, it so much resembles a small bear that many writers have placed it among the *ursida*. The head is rather pointed and bear-like, the eyes and ears very small, the body long and stout, the legs short and robust, the claws

large and sharp, the soles covered for the most part with bristly hairs, and the tail short and bushy. The glutton of Europe (*G. luscus*, Linn.) is about as large as a badger, of a deep brown, darkish on the back. The voracity of this animal, though great, has been much exaggerated. It is nocturnal, inhabits the coldest countries, as Russia and Siberia, and is active all winter. The American glutton, called also wolverene and carcajou, seems to be a paler variety of the *G. luscus*; the color is dark brown above, passing into black; a pale band runs on each side from the shoulder around the flanks, uniting on the hips; tail with long bushy hairs. The inner fur is soft and short, the outer long and coarse, like that of the black bear; across the forehead, on each side of the neck, and between the legs, are patches and tufts of white hairs. The average length to root of tail is 2½ ft., the tail from 10 to 12 in., and the height at shoulder about a foot; the width of the hind feet is nearly 5 in., so that their tracks in the snow are not unlike those of the bear. The wolverene is confined almost exclusively to the northern regions of the continent, being most abundant in the Rocky mountains near the arctic circle; it is occasionally seen in northern New York, and in the west has been found as far south as Great Salt lake. The strength, agility, cunning, and voracity attributed to the glutton by the older writers are mostly fabulous; it is by no means ferocious, is slow and heavy in its motions, not remarkably voracious, neither strong nor agile enough to pounce upon and kill deer and other large game, and avoids entering water in pursuit of prey. The wolverene generally hunts at night, spending the day in holes and caves; its food consists principally of mice, marmots, and other rodents, grouse and other birds which have plunged under the snow; there is no proof that it destroys the beaver, except occasionally; it may sometimes finish larger animals disabled by the hunter, by old age, or by accident, and when very hungry will eat carrion. It is notorious for following the traps of the hunter, and stealing therefrom both the bait and the captured animal, and for digging up and destroying *caches* of provisions. The wolverene is very suspicious, and rarely caught except in carefully concealed steel traps; it is very strong for its size, its weight being from 25 to 30 lbs. The young are produced once a year, two to four at a time. The fur of the wolverene is used for muff's and sleigh robes. The specific name *luscus* was given by Linnaeus to an American animal, which happened to have but one eye; should the European glutton be separated from the wolverene, it would be properly called *G. borealis* (Nilsson).

**GLYCERINE** (Gr. γλυκύς, sweet), the sweet principle of oils, a triatomic alcohol, the base of the compounds found in animal fats and also in some vegetable substances, discovered by Scheele in 1779. Its composition is represented by the formula  $C_3H_5O_3$ . It is a colorless, transparent, sweet sirup, without odor, of spe-

cific gravity 1.28; it is inflammable, mixes freely with water, taking it from the air, is also soluble in alcohol, sparingly in ether, and dissolves salts that are soluble in water; it does not become rancid by exposure, but with animal tissue may be made to ferment. At a temperature above 600° F. it is decomposed, being converted into acroleine, acetic acid, and inflammable gases. Between 500° and 600° it may be distilled with only partial decomposition. It may be cooled to -4° F. without freezing. Berthelot has succeeded in combining it with the fatty acids, and has thus produced the organic fatty substances, stearine, margarine, oleine, &c. This was effected by keeping the mixture of acids and glycerine at a temperature of 212° for several days in close vessels. At higher heat much less time is required.—Glycerine is a product of the process of saponification. As prepared by the pharmacutists, it is taken up with boiling water from its mixture in a free state with the plumbiferous soap called lead plaster. The plaster is made by boiling together litharge (oxide of lead), olive oil, and water. The oil is decomposed by the lead taking its acids, and the glycerine is thus liberated. When hot water is added in equal quantity to the plaster, the mixture is well stirred, and the liquid part is decanted; any lead that may be present is thrown down by a current of sulphuretted hydrogen, and is got rid of by filtering. The water is finally removed by evaporation at a temperature below 212°, leaving the glycerine. Various other methods of preparing it are in use. The mother liquor of the soap factories affords a convenient source of it. From this it is separated by adding a slight excess of sulphuric acid, heating the solution with carbonate of baryta, filtering, and, after the filtrate has been concentrated by evaporation, taking up the glycerine with alcohol, which is afterward to be distilled off. A hot solution of fat has been decomposed by injecting into it superheated steam. The fatty acids and glycerine, collected in a receiver, separate in two layers, the glycerine at the bottom. The acids can be drawn off, so as to leave the glycerine with no other mixture than water. The method of detecting the presence of glycerine when in small quantity is based on the marked qualities of the substance acroleine into which it is in part converted by heat. If the substance supposed to contain it be separated from foreign mixture as far as possible and rapidly heated, either alone or with a little anhydrous phosphoric acid, the acroleine generated, in case glycerine was present, will be detected by the pungent acrid odor, somewhat like that from the wick of a candle just extinguished. Glycerine is formed in small quantities during the process of alcoholic fermentation. C. Friedl and R. Silva have succeeded in preparing it artificially from the chloride of propylene, which in turn is made without the use of glycerine itself.—Owing to its property of long continuing moist,

and its strong affinity for water, it may be applied to the skin or to mucous surfaces, when it is desired to prevent dryness and to use a bland and soothing application, as in chapped hands or lips, many skin diseases, a parched and glazed condition of the mouth, &c. If applied undiluted, it withdraws water from the moister tissues under it. For external uses it may be advantageously combined with tannin, carbolic acid, or borax, all of which are readily dissolved by it. With starch a plasma of any required consistency may be formed, which takes the place of an ointment, and has the advantage of not being greasy, and being capable of easy removal by washing. Inferior varieties of glycerine may contain irritating impurities. Either alone or with a small proportion of carbolic acid, it is a very useful medium for the preservation of anatomical specimens in a condition of pliability, and is also of great value in microscopic anatomy. Glycerine is a powerful solvent, and may be used in pharmacy to prevent drying as well as decomposition. The vegetable alkaloids dissolve in it readily, and may be used in this form for subcutaneous injection. It has been suggested for internal use in diabetes, instead of sugar, and also as a substitute for cod-liver oil; but experience does not assign to it much value for these purposes. For use in cosmetics and perfumery it is largely manufactured, its soft agreeable qualities, without greasiness or liability to putrefy, rendering it an excellent ingredient in soaps for the toilet, pomade, hair tonics, &c. It is lately employed in the photographic art, and its use is extending for a variety of new purposes. A glycerine ointment of much repute for chapped hands and excoriations is made as follows:  $\frac{1}{2}$  oz. of spermaceti is melted together with a drachm of white wax and 2 fluid oz. of oil of almonds, by a moderate heat; the mixture is poured into a Wedgwood mortar, when a fluid ounce of glycerine is added to it and rubbed till the ingredients are thoroughly mixed and cold. The consumption of glycerine in the manufacture of beer amounts to more than 20,000 cwt. per annum. It also finds extensive use for the following purposes: mixed with water to fill wet gas metres; to lubricate the inside of moulds for plaster casts; to prevent the shrinkage of wooden vessels; to preserve meat, fruit, candies, medicines, mustard, and tobacco; as a hair wash; in soaps and cosmetics; for the extraction of perfumes; to impart elasticity to paper; in various photographic operations; as a solvent for certain aniline colors; in calico printing; in the preparation of leather; as a substitute for oil in delicate machinery; as a float to swimming compasses; in mercurial manometers; as a substitute for alcohol in the preservation of anatomical preparations; to prevent the rusting of instruments; in the artificial production of oil of mustard; to cure wounds, burns, and bites of venomous insects; in the preparation of cements; for throat diseases; in copying ink; in chemistry to prevent

the precipitations of the heavy metals; and very largely in the manufacture of the explosive compounds nitro-glycerine, dynamite, dualline, and lithofracteur. (See EXPLOSIVES.)

**GLYNN**, a S. E. county of Georgia, bordering on the Atlantic, and bounded N. by the Altamaha river; area, about 400 sq. m.; pop. in 1870, 5,376, of whom 3,450 were colored. It is traversed by the Macon and Brunswick and the Brunswick and Albany railroad. The surface is level and occupied partly by sandy pine barrens, partly by vast swamps, which when drained are productive. The sea island cotton grows here in perfection. Several islands on the coast, one of which is about 12 m. long, are included in the county. The chief productions in 1870 were 15,589 bushels of Indian corn, 6,774 of sweet potatoes, 167 bales of cotton, and 740,880 lbs. of rice. There were 2 manufactories of tin, copper, and sheet-iron ware, 1 iron foundry, and 4 saw mills. Capital, Brunswick.

**GLYPTODON**, a gigantic fossil mammal, belonging to the edentate order with the *megatherium* and *mylodon*, but to the family *dasyptidæ* or armadillos, found in the post-tertiary

*Glyptodon clavipes*.

deposits of the pampas of South America, and especially in the neighborhood of Buenos Ayres. This animal, with the fossil genera above mentioned, establishes the transition between the sloths and the armadillos, and also indicates some pachyderm affinities. Four species have been described by Prof. Owen, of which the largest is the *G. clavipes*; this species, in the structure of the foot and the articulation of the lower jaw, approaches the pachyderms; it resembles the megatherioids in the strong descending process of the zygomatic arch, compressed from before backward; the cranium was protected by dermal plates, and its well developed ridges indicate the existence of very powerful muscles. The teeth, eight on each side of each jaw, have a large proportion of hard dentine, and are characterized by two lateral sculptured grooves, whose wide and deep channels divide the grinding surface into three portions; hence the generic name applied by Owen, which means "sculptured tooth." The back and sides were covered by a carapace composed of thick polygonal bony plates, united by sutures, smooth on the inside, rough and sculptured externally, to the number of more than 2,000. The length of the largest living armadillo, covered with a flat-

tened shield, is about 3 ft.; the size of the glyptodon may be imagined from the measurement of its carapace in the museum of the royal college of surgeons: the length, following the curve of the back, is 5 ft. 7 in.—in a straight line, or the chord of the arc,  $4\frac{3}{8}$  ft.; the breadth, following the curve, is  $7\frac{1}{8}$  ft.—in a straight line,  $3\frac{1}{8}$  ft. The tail measured  $1\frac{1}{2}$  ft. in length, and 14 in. in circumference at the circular base; it was slightly depressed toward the apex, and gently curved, with the concavity upward; the caudal vertebrae were enclosed in an inflexible sheath of bony plates, terminated by two ossicles, like a bivalve shell, enabling it to pierce the soil if necessary. The feet were short and stout, armed with depressed nails. The glyptodon, in its firm, convex carapace, scale-covered tail and head, short limbs, and consequent slow motions, presents many external analogies to chelonian reptiles, and in its size and shape must have resembled rather the living Galápagos tortoise than the great armadillo. Like the living armadillo, the extinct glyptodon was confined to the warm parts of South America. Other species described by Owen are *G. ornatus*, *G. reticulatus*, and *G. tuberculatus*, all obtained from the vicinity of Buenos Ayres.

**GMELIN.** I. **Johann Georg**, a German naturalist, born in Tübingen, June 12, 1709, died there, May 20, 1755. In 1731 he became professor of chemistry and natural history in St. Petersburg. In 1733-'43 he made a scientific journey through Siberia. In 1747 he returned to Tübingen, and in 1749 was appointed professor of botany and chemistry there. His *Reisen durch Sibirien* (4 vols., Göttingen, 1751-'52) and *Flora Sibirica* (4 vols., St. Petersburg, 1749-'70) are his principal works. II. **Samuel Gottlieb**, a German botanist, nephew of the preceding, born in Tübingen about 1744, died at Akhmetkent, in the Caucasus, July 27, 1774. He was professor of botany in St. Petersburg, and travelled extensively through southern Russia and the adjacent countries. While on his way from Derbend to Kisliar, he was seized and imprisoned by the khan of the Kaitak tribe, and died of privation and ill treatment. His chief works are *Historia Fucorum* (1768), and *Reisen durch Russland zur Untersuchung der drei Naturreiche* (4 vols., 1770-'84), of which the concluding part is by Pallas. III. **Johann Friedrich**, nephew of Johann Georg, born in Tübingen, Aug. 8, 1748, died in Göttingen, Nov. 1, 1804. In 1771 he became professor of natural history and botany at Tübingen, and in 1778 professor of medicine and chemistry at Göttingen. He published, among other works, *Onomatologia Botanica completa* (10 vols., 1771-'8); *Allgemeine Geschichte der mineralischen Gifte* (1777); *Allgemeine Geschichte der Pflanzengifte* (1777); and *Geschichte der Chemie* (3 vols., 1797-'9). He was also the editor of the 13th edition of Linnaeus's *Systema Naturæ*. IV. **Leopold**, a German chemist, son of the preceding, born in Göttingen,

Aug. 2, 1788, died in Heidelberg, April 13, 1853. He was educated at Göttingen, Tübingen, and Vienna, and from 1817 to 1851 was professor of medicine and chemistry at Heidelberg. In 1820 he made with Tiedemann a series of experiments on digestion, the result of which was published in his *Die Verdauung* (2 vols., 1826-'7). His principal work is his *Handbuch der theoretischen Chemie* (3 vols., 1817-'19; 5th ed., completed by Schlossberger, List, and Liebig, 7 vols., 1853-'62). There is an English translation of this work, by Henry Watt (9 vols., London, 1848-'55).

**GMÜND**, or **Schwäbisch-Gmünd**, a town of Württemberg, in the circle of the Jaxt, on the Rems, 28 m. E. N. E. of Stuttgart; pop. in 1871, 10,739. It has a Latin school, a Catholic normal school, institutions for the blind and the deaf and dumb, an insane asylum, two hospitals, important manufactures of gold, silver, copper, and bronze ware, and considerable hop culture.

**GNAT**, a name commonly given to the family *culicida*, of the proboscidean division of the order *diptera* or two-winged insects; the cousin of the French, the mosquito of the

1. Female (greatly magnified). 2. Male.

United States. The gnats belong to the genus *Culex* (Linn.), which is characterized by a soft, elongated body; long legs; large head and eyes; long, many-jointed antennae, most plumose in the males; uniform and hairy palpi, longest in the males; a sucking proboscis, formed of a membranous sheath enclosing from two to six sharp bristles or lancets, which take the place of jaws, and whose punctures, therefore, are properly called bites; the side pieces of this apparatus serve not only as suction tubes, but as supporters and protectors of the lancets; wings horizontal, delicate, and many-veined; the winglets, two little scales behind the wings, and moving with them, are small; behind these are the knobbed balancers or poisers. The old genus *Culex* was divided by Meigen into three, and was by him restricted to such gnats as have the palpi in the males longer than the proboscis, and very short in the females; the other two were *Anopheles* (Meigen), in which the palpi of the males are as long as the proboscis, and *Aedes* (Hoffmannsegg), in which they are very short in both sexes; to these were afterward added *Sabethes*, with palpi shorter than proboscis; *Megarhinus*, with very long recurved proboscis and short palpi; and *Psorophora*, with a small

appendage on each side of the prothorax. Other genera, ill-characterized for the most part, have been added by modern systematists. The names gnat and mosquito are also given in some places to members of the family *tipulada*; and our own mosquitoes belong to several genera, among which is the genus *culex*, properly confined to the more northern regions of the continent. Dr. Harris mentions five species of *culex* and one of *anopheles* as found in New England; to these many species and several genera must be added. Some species are active by day, others only by night, but both are equally fond of human blood; the former are found principally in marshes and damp woods and rarely in houses, and are of more brilliant colors than the nocturnal species. The males with plumed antennæ do not annoy us by their bites, but simply flit from flower to flower, sipping the dew and sweet juices, requiring but little if any food, propagating their species, and soon after perishing. The female gnats are most persistent biters and annoying musicians, at almost all seasons of the year; from the tropics to Lapland and arctic America, man is obliged to adopt some contrivance to protect himself from their attacks, either the thick coat of grease of the northern regions, the sand bed of the tropics, the smoky smudge of the woods, or the mosquito bars and curtains of civilized life. Gnats have been known to appear in such swarms as to constitute an insect plague, darkening the air like clouds of smoke, arresting the progress of invading armies, and rendering whole districts for the time uninhabitable; attacking not only man but beasts, and, even when not biting, filling every crack and corner with their countless multitudes. When we consider the immense number of these insects, and the comparatively small proportion which can ever taste human blood, we must admit, what experiments with sweetened fluids have confirmed, that vegetable juices form the food of the greater number of females, and perhaps the natural food of all; many males probably do not eat at all. The sucking apparatus is admirably contrived for obtaining fluids, animal or vegetable, and these insects are provided with a sucking stomach independent of the proper digestive cavity. The sucker is well described and figured by Réaumur in his "Memoirs;" the flexible sheath gives support to the lancets while they penetrate the skin; the point of the combined lancets is sharper than the finest needle, so that the size of each of the several weapons must be very small; the wounds made by this instrument would be insignificant, were it not for an irritating secretion from the proboscis, which in some delicate skins produces obstinate itching, and, in rare instances, even irritable ulcers.—The metamorphoses which gnats and mosquitoes undergo are very curious. The eggs are deposited in almost any natural or artificial receptacle for fresh water, and are arranged in a boat-shaped form; fixing herself

by the four anterior legs to some object at the surface of the water, the female crosses her hind legs in the form of the letter X; bringing the latter close to the end of the body, on a level with the water, the first egg is received and retained in place by the crossed legs; as the eggs are extruded they are placed side by side vertically, adhering firmly together by the glutinous substance which covers them; when the stern of the egg raft is properly raised, it is pushed further from the body by the succeeding ova, always retained in place by the legs on the sides; when the raft is about half made and its shape is determined, the legs are uncrossed and placed parallel, and the prow of the boat is narrowed and raised like the stern. The boat is always of the same shape, containing from 250 to 350 eggs, and is abandoned by the mother to the mercy of the winds and waves, which can neither sink, wet, nor break it up; even a temperature below freezing cannot destroy the life within these eggs. The larvæ come out in a few days from the lower end of

1. Wing of gnat, showing nervures and small cells. 2. Termination of abdomen of male. 3. Termination of abdomen of female. 4, 5, 6. Modes of operation of gnat's sucker. 7. Gnat's eggs. 8. Boat of gnat's eggs.

the eggs, which are arranged somewhat like the seeds of the ripe sunflower, and the empty shell boat is soon destroyed by the weather. The larvæ of gnats and mosquitoes are the well known "wrigglers" seen in warm weather in almost every collection of standing water; they remain, as it were, suspended from the surface of the water, head downward, breathing air by means of a respiratory tube which goes off at an angle from near the end of the body, communicating with the tracheæ; the tube and the terminal joint are provided with radiating hairs; the head is round, distinct, with antennæ and ciliated organs which keep up a constant current of water toward the mouth, and bring within their reach the minute animalcules on which they feed; the thorax and ten-jointed abdomen are furnished with lateral pencils of hairs. If disturbed, these larvæ quickly wriggle to the bottom, but soon come again to the surface and suspend themselves by the respiratory tube. Some species are comparatively free from hairs in

this condition. After remaining in the larva state from five to fifteen days, according to the weather, and changing their skins two or three times, they are changed into pupæ, called tumblers from the manner in which they roll over and over in the water by means of the fin-like paddles at the end of the tail; they are very quick in their motions, and swim with the head upward; the respiratory openings are at the end of two tubes situated just behind the head, so that the little tumblers remain near the surface, head upward, to take in air; in this state, which lasts five or ten days, according to circumstances, the insect takes no food; the future gnat can be distinguished through the transparent covering of the pupa. When the perfect insect is ready to come forth, the pupa skin bursts open on the back toward noon on a warm, still, sunny day, and the head of the gnat makes its appearance, followed soon by the thorax; this is a process of great danger to the insect, as the slightest breeze would tip over the emerging form, and consign it to certain death in the water; after it has succeeded in raising its body except the tail, and stands erect like a mast in the pupa shell boat, it extricates the front pair of legs and places them for support on the surface of the water; the heavy and wet wings are now slowly unfolded, that the sun and air may dry them; this effected, the danger is over, and the other legs are drawn forth and extended on the edge of the pupa case, the body is stretched out, the antennæ and proboscis elevated; by this time the wings are dry and fully expanded, and the insect flies off to revel among the flowers or in search of blood, according to the sex. The source of the buzzing noise has been much discussed by naturalists, and is still the subject of dispute; it has been ascribed to the mouth by Mouffet, to the friction of the base of the wings against the chest by Kirby; the winglets, the poisers, the motion of the wings, the rapid passage of air through the thoracic stigmata, and the vibrations of the thorax from the contraction of the muscles of the wings, have been supposed to be the cause by other entomologists; by whatever organ it be produced, Siebold says it is always due to the action of voluntary muscles, and has no connection with the respiratory system. It is probable that the sound is produced by the combined action of the wings and by the thoracic vibrations consequent thereon. It has been estimated by Baron de la Tour that the gnat vibrates its wings 50 times in a second. This very rapid movement probably depends on a peculiar form of muscle which has been detected in the mosquito and other *diptera*; the fibrillæ are not bound together as in ordinary striated muscles, but are separate and parallel, formed by the aggregation in a linear series of little disks with regular interspaces; contraction of these independent fibrillæ takes place by the approximation of these disks to each other; some are contracting while others are

relaxed, so that a constant and rapid movement of the wings is secured. It is certainly a remarkable example of the extent of modern microscopic investigation, that the minute muscles of the wings and legs of the mosquito can be dissected and studied. Some of the biting *culicidæ* do not make a boat of eggs, but string their ova end to end; others deposit them in soft mud or in dry sand; but all require moisture in the larva state. As the eggs are developed into the perfect insects in about three weeks, many broods are hatched in the course of the warm season, fully explaining their occurrence in large numbers; fortunately only a small portion of the pupæ succeed in extricating themselves from their cases; thousands of them perish by drowning, and are devoured by fish, reptiles, and aquatic insects; the perfect gnats supply food for carnivorous insects, the great tribe of fly-catching birds, and the bats.—The family of *tipuladæ* are also called gnats; these are often seen performing their aerial dances during the summer, and in sheltered places even in mild days in winter, preferring the decline of day; these dancing companies are said always to consist exclusively of males; any attempt to intrude upon their sportive circles shows their quickness of vision and of motion, as the whole company is at once removed to a distance. These gnats sometimes crowd into houses in immense numbers.

**GNEISENAU, August**, count, a Prussian general, born at Schilda, Oct. 28, 1760, died in Posen, Aug. 24, 1831. He served in the Austrian army, and in that of the margrave of Anspach-Baireuth, with whose troops he served in America under the English, shortly before the close of the revolutionary war. He became captain in the Prussian army in 1789, and after the battle of Jena was appointed commander of the fortress of Colberg (1807), and held the place till the peace of Tilsit. The resentment of Napoleon caused his dismissal (1809), but he was sent on secret missions to various courts. Afterward he was attached to Blücher's army as quartermaster general, and as chief of the staff. (See BLÜCHER.) He took a leading part in the Silesian campaign of 1813, and after the battle of Leipsic was made lieutenant general. He rendered important services during the campaign of 1814 in France, and is said to have advised the march to Paris. After the peace he was made count and general, and received a large estate. After the return of Napoleon from Elba he again served with Blücher, and effected a skilful retreat from Ligny (June 16), enabling the Prussians to reappear at Waterloo (on the 18th), and to decide the fate of the campaign. He now took part in the negotiations for peace, was made commander of the Rhenish corps, and accompanied Blücher to England. Disappointed in his expectation of constitutional liberty, he tendered his resignation. In 1818 he was appointed governor of Berlin, and in 1825 field marshal; and in 1831, during the Polish insurrection, he commanded

the army of observation on the Polish borders, soon after which he died of cholera.

**GNEISS**, one of the metamorphic rocks, of the same composition with granite, from which it differs in presenting the three ingredients, quartz, mica, and feldspar, in tolerably distinct layers. The whole mass is often divided into distinct beds or strata, and these exhibit a tendency to cleave along the planes in which the mica is most largely distributed. By increased proportion of mica and loss of feldspar, it passes into micaceous slate. The name gneissic is sometimes given to the group of metamorphic rocks, including the micaceous and hornblende slates, quartz rocks, &c. They are also called hypozoic in reference to their position beneath the fossiliferous strata. The series is familiarly known in the eastern and middle states, ranging through Vermont, Massachusetts, the S. E. part of New York, northern New Jersey, eastern Pennsylvania, Maryland, and Virginia. The gold region lies in this group.

**GNEIST, Rudolf**, a German author, born in Berlin, Aug. 13, 1816. He is professor of jurisprudence in and pro-rector of the university of Berlin, has been a leading liberal member of the Prussian chamber, and is the author of *Das heutige englische Verfassungs- und Verwaltungsrecht* (2 vols., Berlin, 1857-'60), *Die Geschichte des Selbstgovernment in England* (1863), *Geschichte und heutige Gestalt der Aemter und des Verwaltungsrechts in England* (2 vols., 1866), *Freie Advokatur* (1867), *Die preussische Kreisordnung* (1870), *Der Rechtsstaat* (1872), and other works on Roman and German jurisprudence and British institutions.

**GNESEN** (Pol. *Gniezno*), a town of Prussia, in the province and 30 m. N. E. of the city of Posen; pop. in 1871, 9,910. It is surrounded by walls, has a fine cathedral and other churches, an ecclesiastical seminary, a monastery, and a nunnery, and is the seat of a cathedral chapter. Four annual fairs are held there. It was the capital of Poland till 1820, when it was superseded by Cracow. It has been many times besieged, taken, and pillaged. The archbishops of Gnesen were the primates of the state, and acted as vicars during the often disputed elections of the kings.

**GNOSSES**, or **GNOSIS**. See **CROSSUS**.

**GNOSTICS** (Gr. *γνώσις*, knowledge), a name given to various heretical sects in the early Christian church. We know them mainly through their opponents, almost nothing remaining of Gnostic writings except the fragmentary quotations found in orthodox authors. Gnosticism was a natural result of the contact of Christianity with oriental and Greek philosophy, and was the earliest attempt to construct a philosophical system of faith. It undertook to answer the most difficult questions, such as that of the origin of evil, and soon became extravagant, and met the opposition of the leading Christian writers. Gnosticism was now generally condemned as heretical, and, after having been most prosperous in the

2d century, declined in the 3d, and in the 6th came, with other heresies, under the ban of the Justinian code. It was a speculative system, and exercised little influence upon the masses of the people. It was also mainly confined to the eastern church, and had little to do with the development of the West.—There are three principal theories of the character of Gnosticism. Baur treats it as a philosophy of religion resulting from the comparison of various religious systems; Neander as a fusion of Christian ideas with oriental theosophy, caused by the prevalence of sensuous ideas within the church; Möhler as an intense and exaggerated Christian zeal, seeking some practical solution of the problems of sin and evil. All minor theories of the purpose and motives of Gnosticism can be comprehended in one of these; and these three agree in the general definition, that Gnosticism is an attempt to solve the great problems of theology by combining the elements of pagan mysticism with the Jewish and Christian traditions. It is impossible to make an accurate definition of a system of which the speculations are so vague, and the materials for judgment so scattered and fragmentary. Different writers vary widely in their method of classifying the various Gnostic schools. Some classify them by opinions, some by origin, and some by locality. The chief Gnostic ideas may be summed up under seven heads: 1. God is infinitely removed from the actual world, enclosed in the abyss (Gr. *βάθος*), with which he is in fact confounded; he is separate from every work of temporal creation, incomprehensible by any mortal, and communicates with the lower world only through the mediation of the æons (Gr. *ἄων*, age or era), whom he sends forth from the depths of his grand solitude. He has infinite development in the forces which he sends, but no personal or special providence. He is the sum of being, yet the extreme of abstraction, and is even called the Not Being (*ὄνκ ὄν*). 2. Below the abyss, in which God alone dwells, or surrounding this abyss, is the Pleroma (Gr. *πλήρωμα*, fullness), that world of light and glory which the æons inhabit. These æons are emanations from God's central fullness, are embodiments of his divine attributes, and fulfil the functions denoted by their several names. Among the higher æons are Mind, Reason, Power, Truth, and Life. All of these are styled æons, because they are in some way the representatives of the Eternal Being; but only one of them, Nous or Mind (*νους*, or in late authors *νοῦς*, intellect), proceeds directly from the Deity. The others emanate in descending succession from the first æon. One Gnostic writer compares the emanation of these æons from the Supreme Being to the tones of the voice lessening steadily to a faint echo. The number and characteristics of these æons are variously stated; according to Valentinus, there were 365 of them; but according to all, only the lowest of them has anything to do with the material world, occupying the point

where the spiritual and material worlds touch each other. The office of the higher æons is to people and take care of the spiritual world. 3. Matter is infinitely separated from God, and the material world is the antithesis of the spiritual world. Hyle (*ὕλη*, matter) is either absolute deadness and emptiness (*κένωμα*), or is a positively evil substance. The creator of this material universe is the Demiurge. He is himself a creature of the lowest of the æons, Achamoth. He not only creates and rules the terrestrial world, but has equal sovereignty over the planets and stars. He fulfils, or as some say usurps, the functions of the infinite God. He appears in Jewish history as Jehovah. Other names by which he is known are those of Archon and Jaldabaoth, the son of Chaos. The immediate work of the Demiurge is evil, and it takes the world of man and matter further away from God and the world of light. 4. Man has a threefold nature, of spirit, of body, and of soul. His soul-nature stands between the other two, and forms their connecting bond. Men are divided into three classes, according to the predominance of one or other of these three natures. The first of these classes enjoy a light from the world of æons; the second are left wholly to material and hyle influences; while the third are under the direction and influence of the Demiurge, who can save them from utter debasement, but cannot give them spiritual life. Historically, the Christians constitute the spiritual world; the pagan world forms the carnal class; and the Jews occupy the intermediate place. But in dividing the Christians of their own time, the Gnostics numbered two classes, the select few of their own number who were admitted to the divine secrets, and the large body of common believers, who were not able to rise above the psychical condition. Some of them maintained that though man as connected with matter is by nature sinful, and though the Demiurge wished to create man in his own image, yet unwittingly he reproduced in this work of his breath, not his own image, but a shadow of that divine original which moved before his imagination. Man is better than the intention of his creator. 5. Redemption reaches only the pneumatic and psychic classes; the carnal or hyle class are destined to annihilation when their material life shall close, and with them such of the psychic class as have not accepted the influence from the Pleroma. The instrument of redemption is the æon Christ. This æon came down from the spirit world, assumed bodily shape without being actually united to any material body, and walked among men in Judea as Jesus of Nazareth, not a real human person, but an optical illusion, the phantasm of a spiritual idea. Some of the Gnostics were willing, indeed, to speak of the human life of Christ; but all denied that his body was composed of the elements of corrupt and sinful matter; it was an ethereal body of more delicate fabric than the common human body. Hunger would not

impel him to eat, nor thirst to drink. Yet this ethereal body was too gross for the Pleroma, and was left in the sun at Christ's ascension. The advent of Christ upon the earth was not the birth of a prophet, or the coming merely of a promised Messiah, but a spiritual apparition to overthrow the work of the evil spirit—"an incarnation of the spirit of the sun." The presence of Christ anywhere made men conscious of this divine nature. They might doubt of the humanity of Christ, but not of his divinity. The process of redemption, in the Gnostic theory, is the communication through the æon Christ of a divine life to the world of man, the revelation of that life through this mediator. Christ redeems the world as he draws the spiritual in the world toward the heaven of God. His sufferings and death have no influence in the redeeming work, since, in the first place, they were illusory, and in the second place, sufferings do not redeem, but only punish. The manifestation by his acts and words of the spirit of God made Christ the redeemer. Some expressions in Gnostic writings might be interpreted as teaching views of redemption more in harmony with the church creeds; but nowhere was any doctrine of atonement stated, or any stress laid upon the crucifixion as its central point. Marcion extends the redemption into the world of Hades, and maintains that Christ descended into hell to lead back the virtuous and believing heathen to share salvation with the spiritual Christians. In regard to the means of profiting by the redemption of Christ, the Gnostic teachers were not agreed. Marcion taught a doctrine resembling that of Paul, making faith the means of justification and the ground of reconciliation. But most of the sect held that only "gnosis," the rare superior intelligence and comprehension of divine truth, could enable men to receive the gift of Christ. This spiritual knowledge was the evidence of salvation to believers. The actual manner of union between Christ and his redeemed ones is very vaguely described in the Gnostic writings, and their language in speaking of redemption and its issues is confused. 6. Although the Gnostics were charged with boasting that they had schools rather than churches, yet they held to a church which should have a twofold life, for the mass of believers, and for the initiated: for the first, common exoteric doctrines, and for the second, spiritual esoteric doctrines, revealed to a secret sacred society within the proper circle of the church. Practically they did little, and many of them were content to theorize about spiritual truth, while submitting to the recognized ecclesiastical order. Baptism was to them the important rite, since Jesus became Christ at his baptism, and through this rite the higher spirit was imparted to the sensuous soul. It was the sign of their emancipation from demiurgic rule. A few objected to baptism as too physical a rite, but most of them celebrated it with great show and solemnity.

The Lord's supper was to them of less importance, being only the sign of a material feast, on the reality of which their views of the nature of Christ threw doubt. Some of them kept the feast days of the church, and the followers of Carpocrates allowed the use of images both of Jesus and the saints. While the idea of the church was to a great extent discarded, much of its ritual and its splendor was retained. 7. In practical morals two tendencies are to be observed in the Gnostic schools. On one side is the ascetic tendency, which seeks a complete emancipation from matter and from bodily passion, as the seat of sin; on the other side the licentious tendency, which plunges into excess, on the plea that sensual passion is most surely overcome by satiety. Many of the charges brought against this latter class of Gnostics are, however, to be taken with large abatement. There is no evidence that their average morality was below that of the orthodox Christians, or that the ascetic tendency was carried to such extremes among them as among the Jewish Essenes or the later Christian hermits. Gnosticism, in the 2d century at least, was rather a speculative than a practical heresy, a system of intellectual vagaries rather than of moral corruptions.—In speaking of the principal Gnostic teachers, the geographical division may be adopted as most convenient, if not most philosophical. Of the precursors of Gnosticism before the formation of its principal schools are mentioned: Simon Magus, whose authentic history is related in the Acts, but of whom legends abound, and after whom the sect of the Simonians was named; Menander, said to have been a disciple of Simon; Cerinthus, who considered Judaism a preparation for Christianity; Nicolaus, of whom nothing is known except that he is reckoned as the founder of the sect of the Nicolaitans, noted for their lax morality, and mentioned in the Apocalypse. Of the Syrian school, the chief characteristic of which is dualism, the principal teachers were: 1. Saturninus, a follower of Menander, who lived at Antioch about the year 125, in the reign of Hadrian. He maintained that the lowest æon was formed from the spirits of the seven planets; that the evil spirit formed a race of hylic men to counteract the race formed by this æon; and that Christ was the æon Nous in a visible but not corporeal body. His school, never very numerous, was confined to the neighborhood of Antioch, and was hardly known in the succeeding century. 2. Bardesanes, who flourished at Edessa in the latter half of the 2d century. (See BARDESANES.) 3. Tatian, who lived in the 2d century, and is commonly reckoned among the Christian apologists. (See TATIAN.) In the Egyptian school, characterized by the emanation theory, the principal teachers were: 1. Basilides, who taught in Alexandria about the year 120, whose followers, the Basilidians, existed as late as the 4th century. (See BASILIDES.) 2. Valentinus,

an Alexandrian Jew, who taught in Rome about the middle of the 2d century, and died in Cyprus about the year 160. His system of æons is divided into three series of 15 pairs, an ogdoad, a decad, and a dodecad. They are male and female. His "threefold Christ" differs from that of Basilides. His elaboration of Gnostic ideas was more complete and ingenious than that of any other writer, and his influence was longer and wider in its extent. J. Matter numbers seven distinguished names among the successors of Valentinus, five of whom founded schools; these are Secundus, Ptolemy, Marcus, Colarbasus, Heracleon, Theodotus, and Alexander. 3. The Ophites, or Naasenes, a powerful sect, yet without any distinguished name among their teachers, who traced their doctrine to James, the brother of the Lord, and existed at a later period than the other Gnostic sects. As their name implies, the serpent was for them a sacred emblem. They regarded the fall of man as a progress rather than as a loss, named the Jewish Jehovah "Jaldabaoth," or the God of chaos, preferred Judas to the other disciples, affirming that he betrayed Christ to destroy the kingdom of God's enemy, and denied that the real Christ was ever crucified. The Sethites and Cainites were branches of this sect. The moral character of the Ophites was bad, and the sect came not only under the constant rebuke of the church teachers, but under the imperial ban. Of the Gnostics of Asia Minor, the one eminent name is that of Marcion, an austere moralist and a vigorous reasoner. He taught at Rome about the middle of the 2d century. His system is characterized by the constant antithesis between Christianity and Judaism, by a rejection of the Old Testament and of all apostolic authority except that of Paul, and by a rigid asceticism. His followers were numerous even to the time of Mohammed. Of the Gnostics not localized, but mostly related by their doctrines to the Gnostics of Egypt, may be mentioned the schools of Carpocrates and his son Epiphane, the Antitacts, the Bortonians, the Phibionites, the Archontics, the Adamites, and the Prodicians. Hermogenes of Carthage is also by some regarded as a Gnostic teacher.—While the particular sect and schools of the Gnostics had disappeared almost wholly in the 6th century, their opinions survived to a much later age, seriously affecting not only the orthodox faith, but appearing in many of the famous and troublesome heresies. Their earlier influence is to be noticed in the views of the Ebionites and the Docetæ, in the speculations of the Clementine Homilies, in the radical theories of Montanism, in the fantasies of the New Platonists, and above all in the powerful and wide-spread Manichæan heresy. Some have also endeavored to find traces of Gnosticism in the Sabellian, Arian, and Pelagian heresies. In the 7th century their doctrines were repeated by the Panlicians, in the 9th by the Athingianians or "chil-

dren of the sun," about the close of the 11th by the Catharists, and in the 12th by the Bogomiles of Byzantium. Some of the opinions of the knights templars and of the Waldenses seemed to be borrowed from this source, and the reveries of Spanish and German mystics are not unlike the hymns of Bardesanes. The sources from which our knowledge of Gnosticism is drawn are the single Gnostic work *Pistis Sophia*, translated from Coptic into Latin by M. G. Schwartze (edited by J. H. Petermann, Berlin, 1851); Irenæus's *Ελεγχος τῆς ψευδαγνίου γνώσεως* (edited by Stieren, Leipsic, 1853); fragments from Irenæus and Hippolytus (edited by Emanuel Miller, Oxford, 1851); and the works of Ignatius, Justin, Tertullian, Clement of Alexandria, Origen, Eusebius, Philastrius, Epiphanius, Theodoret, Augustine, Plotinus, and others. The more important modern works which treat of Gnosticism are: Neander, *Genetische Entwicklung der vornehmsten gnostischen Systeme* (Berlin, 1818); E. A. Lewald, *De Doctrina Gnostica* (Heidelberg, 1818); Möhler, *Ursprung des Gnosticismus* (Tübingen, 1831); Baur, *Die christliche Gnosis, oder die christliche Religionsphilosophie in ihrer geschichtlichen Entwicklung* (Tübingen, 1835); Matter, *Histoire critique du gnosticisme* (2d ed., 3 vols., Paris, 1843-44); the church histories of Mosheim, Neander, Gieseler, Hase, and Schaff; Beausobre's "History of Manichæism," Münster's "Ecclesiastical Antiquities," Ritter's "History of Philosophy," Dorner's "Christology," and Bunsen's "Hippolytus and his Age."

**GNU**, a hollow-horned ruminating animal, inhabiting the plains of southern and central Africa, generally classed with the *bovidæ* or ox family, of the genus *catoblepas* (H. Smith) or *connochetes* (Gray); the *wilde beest* of the Dutch colonists at the Cape. It is one of the most singular of animals, having the head and horns of a buffalo, the body and mane of a horse, and

in both sexes, above and behind the eyes, close together at their origin, descending at first downward and outward, then curving upward and backward, flattened at the base, cylindrical at the tip, rough and irregular. The hair on the brows and forehead is long and shaggy,

Brindled Gnu (*Catoblepas gorgon*).

giving a fierce expression to the face; the neck has a rigid mane above, and a long, hairy dewlap below; the shoulders are deep, and surmounted by a moderate hump; the body is rounded like that of a horse, and the limbs delicately formed; the tail is moderately long, with a brush at the end; the hair elsewhere on the body is short; the hoofs are rather large for the limbs, and the skin of the knees is bare and callous, from their habit of going on their knees in attack and defence. The general color of the common species (*C. gnu*, H. Smith) is yellowish tawny, darkest on the back and legs, with the tips of the long hair blackish. The gnu, though clumsy in appearance, is very swift and active, galloping over the plains like a horse, and feeding in large herds like wild cattle; when alarmed, it rarely takes to flight until it has examined into the cause of the danger, a curiosity of which the hunter is able to take advantage; it is very pugnacious, and is tamed with difficulty. The common species is about 3 ft. 10 in. high at the shoulders, and 6½ ft. long from nose to tail. A second and larger species is the *kokoon* or brindled gnu, *blauwe wilde beest* (*C. taurina et gorgon*, H. Smith), which measures about 5 ft. at the shoulders and 7½ ft. from nose to tail, the tail 1½ ft., and the horns about 2 ft. long. The face is blackish, the sides of the head and neck yellowish gray, the latter and the shoulders with vertical dark stripes; the body above and the sides glossy reddish gray; below, and the limbs, reddish brown. Both species inhabit the extensive grassy plains of central

White Gnu (*Catoblepas gnu*).

the limbs of an antelope. The form of the head, neck, and shoulders is decidedly bovine, robust, and clumsy; the forehead wide and flat, the muzzle broad, and covered with hair except the valvular opening of the nostrils; the eyes large; ears long, narrow, and pointed; horns present

Africa, advancing southward after the summer rains to the Orange river, south of which only the common and first named species ranges. Great numbers are killed every year by the Cape colonists, but their annual visitations still continue; the flesh is considered excellent.

**GOA. I.** A Portuguese colony in India, on the W. coast, between lat.  $14^{\circ} 54'$  and  $15^{\circ} 45' N.$ , and lon.  $73^{\circ} 45'$  and  $74^{\circ} 26' E.$ , bounded N. by Sawuntwarree, E. by N. Canara, and W. and S. by the Indian ocean; pop. about 418,000. With the exception of Damaun and Diu, it is the only Portuguese possession in India. It is well watered and fertile, producing rice, pepper, coconuts, betel nuts, and salt. The inhabitants, two thirds of whom are Roman Catholics, are chiefly descendants of Europeans by native women. **II. Old Goa**, a city of the above named colony, and formerly capital of the Portuguese possessions in India, on an island separated from the mainland by the river Mandova, 250 m. S. S. E. of Bombay; pop. about 4,000. The houses are built of stone in the European style, the streets are regular, and the public buildings far surpass everything else erected by Europeans in India, but are falling to decay, and the ruins of the ancient edifices have been used as quarries for building materials in the new town. During the 16th century it was one of the most flourishing European settlements in the East; its walls described a circuit of 6 m., and enclosed a population of 150,000 Christians and 50,000 Mohammedans; but the site is unhealthy, and was abandoned early in the 18th century. St. Francis Xavier was buried there, March 15, 1554; but his remains, with his magnificent tomb, covered with sculptures representing passages in his life, have been removed to the new town. Old Goa is now nearly deserted; but some pains are taken to keep the ancient churches and public buildings in repair. **III. New Goa, Panjim, or Pangann**, situated on the same island, 5 m. nearer to the sea than the old town, on a fine bay S. of a headland called Algoada point, with two lighthouses, is a fortified place, and since 1758 the Portuguese capital in the East; pop. about 24,000. It is the residence of the governor and principal Portuguese inhabitants, and the seat of an archbishop. The principal buildings are the cathedral, custom house, and the palaces of the archbishop and the governor. The trade, once the most important of any place in India, is now trifling, and is limited to the mother country and the Portuguese settlements on the coast of China and Africa. The revenue of the colony is about \$600,000 annually. Goa was taken from the Hindoos by the Mohammedan sovereign of the Deccan in 1469. In 1510 it was captured by the Portuguese, who made it the capital of their conquests in India; and it has ever since remained in their hands except during the period from 1807 to 1815, when it was held by the British. In no part of the world was the inquisition more vigorously maintained than in

Goa. A mutiny of the native troops took place here in November, 1871.

**GOA POWDER.** See supplement.

**GOALPARA**, or **N. E. Rungpoor**, a district of Bengal, British India, bounded N. by Bootan, E. by the district of Camroop, S. by Mymensing and the territory of the Garrow tribes, and W. by Rungpoor and Cooch Behar; area, 4,433 sq. m.; pop. in 1872, 442,761. It produces cotton, tobacco, sugar, and mustard. Though belonging properly to Bengal, of which it formed a part on the acquisition of that territory by the British in 1765, it is often regarded as a district of Assam, with which country it is naturally connected by similarity of climate, soil, &c.—The town of the same name, on the Brahmapootra, 280 m. N. E. of Calcutta, is the chief trading place of the region.

**GOAT** (*capra*, Linn.), a hollow-horned ruminant, of the subfamily *ovina*, which also contains the sheep. The genus is characterized by a convex forehead, nose for the most part straight in its upper outline, and the absence of lachrymal sinuses and secreting glands between the hoofs; the horns, present in both sexes, but larger and more angular in the males, are of a dull yellowish brown color, compressed and nodose, with a sharp edge behind and before, curving backward, but not completing a circle, and the tips never coming forward; their curve, unlike those of the sheep, forms part of a circle, whose diameter is much longer than the head; their osseous nucleus is porous or cellular, communicating with the frontal sinuses; the chin is bearded, the tail very short and naked below, the hoofs as high on the inner as on the outer side, and the mammae, generally two, forming an udder; the nose is covered with hair, except a narrow naked space between the nostrils; the limbs are strong, with a callosity on the carpus. The dental formula is: incisors  $\frac{2}{2}$ ; canines none; molars  $\frac{2}{2} \frac{2}{2} \frac{2}{2}$ ; in all 32 teeth. The hair is never very coarse, and sometimes remarkably fine, with a woolly down underneath. The period of gestation is five months, and the number of young generally two; the female is capable of propagating at seven months, and the male at a year old; the age of the goat may be extended to 15 years, though they are generally old at 6. The males emit a powerful odor, and are libidinous and pugnacious. They ascend giddy heights, and spring with great precision from rock to rock where there seems hardly a possibility of their obtaining a foothold; their sight and smell are acute. The hunting of the wild species is both difficult and dangerous. The goats include the ibex of Europe, Asia, and Africa (see IBEX); the wild *agagrus*, and the Jemlah goat or the jharal. There is no goat indigenous to America, the so-called Rocky mountain goat being in reality an antelope.—The common wild goat (*C. [hircus] agagrus*, Pallas) inhabits the mountains of the Caucasus, Asia Minor, and Persia, and according to some the European Alps. It is higher on the legs than the domestic goat,

and the horns are large in proportion to the size of the animal. The general color is grayish brown above, with a dark dorsal line and blackish tail; the colors are paler in the female. Another wild species is the Jemlah goat (*C. Jemlahica*, H. Smith), with depressed, knobby,

Domestic Goat (*Capra hircus*).

wrinkled horns, a solid, heavy skull, and robust limbs; the hair on the neck and back is abundant, long, and loose, and on the sides of the head very coarse; the tail is very short; the color is a dirty whitish fawn. It inhabits the district of Jemlah, in the elevated mountain chain of central Asia. The *C. corsus* and *C. imberbis* (De Blainville) are believed to be domesticated varieties of this species. The Jhalal of Hodgson is by Gray referred to the same species as the last, forming the genus *hemitragus* (Hodg.); they have four mammae. The domestic goat (*C. hircus*, Linn.) resembles the *C. aegagrus* more than any other wild species. The common goat of the mountainous countries of Europe much resembles the aegagrus, and has in some places become so wild as to be difficult of approach; the ears are small and upright; the size of the body is smaller, the hair coarser, the horns more vertical and turning outward, and the colors more varied. The Persian goat resembles a small aegagrus; the hair is long and coarse. The Welsh breed is large, generally white, with long fine hair, and with vertical horns about 3 ft. long. There are small hornless breeds of goats in South America, the West Indies, and the Pacific islands, supposed to have originated from Africa. The Angora has long soft hair, mostly white, long ears, upright yellowish horns, and a sheep-like look. The famous Cashmere (properly Thibet) breed have long, straight, silky hair, large pendent ears, and slender legs. The Nepal goat is black, of a high and slender figure, with an arched form of nose, and long, hanging,

whitish ears. The goat of upper Egypt is of a brownish color and high stature, with long shaggy hair, arched nose, ample pendent ears, and the upper jaw so much shorter than the under that the lower incisors and chin are exposed.—Goat skins were probably among the first materials used for clothing among the northern nations. The milk of the goat is used for making cheese, and is prescribed as a medicine in debilitated constitutions and pulmonary diseases. In the malarious regions of Asia cow's milk is regarded as a predisposing cause of bilious fevers and diseases of the liver, and goat's milk is therefore substituted. The flesh of the kid is esteemed as food; from the skin are made fine gloves, various garments, and the real Morocco leather; from the hair of one variety are manufactured the costly fabrics of Cashmere. (See CASHMERE.)—The Rocky mountain goat is referred to the genus *capra* by Desmoulins, Harlan, Sundevall, Richardson, Bachman, and Van der Hoeven; but recent examinations go to show that in all its essential features and affinities it is an antelope, and belongs to the genus *aplocerus* (H. Smith). It resembles the goat and merino sheep in its figure and size; the horns are small, conical, smooth, nearly erect, and jet black. The outer hair is long, straight, and white, as fine and soft as that of the Cashmere goat; the chin is bearded; the external fleece hangs down all over the body and upper part of the legs; the under hairs are soft and silky like wool. It inhabits the highest and most inaccessible peaks of the Rocky mountains between the parallels of 40° and 65° N., and is most abundant in Washington territory; it is very difficult to procure; the mountain sheep

Rocky Mountain Goat (*Aplocerus montanus*).

(*ovis montana*, Cuv.), or big-horn, has been often mistaken for it by travellers.—The goats are rarely found fossil, and belong nearly to the same epoch of creation as man, forming probably the first step by their domestication in his progress toward civilization. The goat

was one of the signs of the ancient zodiac (Capricorn); the mythological Pan, the god of shepherds and the supreme power over nature, was represented with the horns and legs of a goat; the *egis*, or shield of Jupiter, was covered with the skin of a goat; this animal was sacred to several ancient divinities, and even under the Jewish dispensation was emblematical of atonement.

**GOATSUCKER**, a nocturnal fissirostral bird, of the order *passeres* or *insessores*, suborder *strisores*, and the family *caprimulgidae*. The family are characterized by a short, very broad, depressed bill, with an immense gape extending beneath the eyes and rendered larger by numerous bristles for arresting their insect prey; the eyes are very large, and easily dazzled by the full light of day; the tarsi are short and weak, the toes long, the hind toe closely united to the base of the inner; the plumage is soft, enabling them to fly without noise. In the sombre colors and texture of the feathers, in the large head and eyes and nocturnal habits, they resemble the owls, but zoologically they come nearest to the swift family. The name goatsucker is derived from the Latinized Greek appellative *caprimulgus*, which originated in the idea that they suck the mamma of goats; the French call these birds *engoulevents*, or wind swallows, and *crapauds volants*, or flying toads, probably on account of the great capacity of the mouth. Like the owls, they hide themselves by day, coming out toward sunset, and pursuing insects on the wing with great rapidity during the twilight; they make no nests, but deposit their eggs on the bare ground or in slight concavities; they are found in all parts of the world, but most abundantly in South America. There are three subfamilies: *steatorniina*, or oil birds, found in the West and East Indies, Australia, Africa, and South America; *caprimulgina*, alone represented in the United States; and *podagerina*, in Africa and South America. In the first subfamily the genus *steatornis* (Humboldt) become so plump on the rich palm fruits of Guadeloupe and Trinidad in the breeding season that their fat is compared to that of olive oil, and as such is permitted to be used during Lent. Some species of the genus *nyctibius* (Vieill.) are as large as a short-eared owl. Among the *caprimulgina* are included the European goatsucker, the North American chuckwill's widow, whip-poorwill, and night hawk, and the South American scissors-tailed goatsucker. The European species (*caprimulgus Europæus*, Linn.) is as large as a thrush, of a gray brown color, undulated and spotted with blackish brown, with a band of white from the bill to the nape; it nestles in the furze, and lays two eggs. From the nature of its food and its method of taking it, and its manner of flying, it is often called the square-tailed swallow; it feeds on nocturnal insects like moths and beetles, and migrates during winter into southern Europe and northern Africa. The chuckwill's widow (*antrostomus Carolinensis*, Gould) is the largest of the

North American species, being about 13 in. long, with an extent of wings of 26 in.; it has very strong bristles at the base of the bill, each with lateral filaments; the wings are long, and the tail slightly rounded; the prevailing color

Chuckwill's Widow (*Antrostomus Carolinensis*).

is pale rufous, the top of the head reddish brown with longitudinal black streaks, the last two thirds of the tail feathers (except the four central) rufous white, with the outer webs of all mottled; the female has no white patch on the tail; it is found in the southern Atlantic and gulf states. The popular name of the bird is derived from the sounds which it utters very clearly and strongly six or seven times in quick succession in a melancholy tone; they are sel-

Leona Goatsucker (*Macrodipteryx longipennis*).

dom heard in cloudy weather, and never, according to Audubon, when it rains. The flight is rapid, graceful, and elevated. It makes its appearance from the south in the gulf states about the middle of March; no nest is made, but the eggs are laid among the dead leaves;

if the eggs be disturbed, the birds remove them in their mouths (according to Audubon, who witnessed the fact), and place them in another locality; they probably remove the young in the same manner. They manifest a great antipathy to all kinds of snakes. They leave the United States about the middle of August. The whippoorwill (*A. vociferus*, Wils.) and the night hawk (*Chordeiles Virginianus*, Briss.) will be described under their proper titles. The scissors-tailed species (*C. furcifer*, Vieill.) of Paraguay is remarkable for the length of the outer feathers of the tail, gradually diminishing to the tip. Among the *podagerinae* is the Leona goatsucker (*macrodipteryx longipennis*, Shaw), a native of Africa, having the innermost quill of the wings extremely prolonged and deficient in webs except at the end, and longer than the bird itself. The genus *podager* (Wagl.) has long wings and short even tail, and short and feathered tarsi; it is found in the warmer parts of South America, frequenting fields and moist places, usually in pairs, but occasionally in large flocks, chasing insects in the full light of day; it lays two eggs on the bare ground. Most of the goatsuckers have the inner edge of the middle claw pectinated, like a comb, for the purpose of cleansing the bristles of the bill from remains of insects and particles of dirt.

**GOBELINS, Manufactory of the**, an establishment in Paris belonging to the French government, devoted to the production of tapestry and carpets. It is situated in the faubourg St. Marcel, upon the Bièvre, being No. 254 rue Mouffetard. It derives its name from the brothers Jehan and Gilles Gobelin, who discovered an improvement in scarlet dye, and erected this building as they believed that the water of the little stream Bièvre possessed qualities advantageous to their art. Jehan, the head of the Gobelin family, died in 1476; some maintain that he was a native of Rheims, and others that he came from Holland. His scarlet dye soon rose into great repute. The establishment was purchased by Louis XIV., and transformed in 1667 into the *manufacture royale des meubles de la couronne*. The royal factory was not only a dye house and a manufactory of tapestry, but an immense workshop in which everything was executed that was needed for furnishing and decorating houses. Engravers in metal and gold and silversmiths produced chandeliers, torch-holders, candlesticks, and statuary bronzes, in keeping with the magnificent tapestry designs, which skilful weavers wrought after patterns furnished by the royal painters; cabinet makers carved, turned, and gilded the wood of the furniture; Florentine artists inlaid beautiful mosaics; and thus everything, even the knobs and locks of windows and doors, was executed in the highest style of art. The royal painter, Lebrun, was the director of this immense establishment. Mignard, who succeeded Lebrun, opened in it a school of design. Though the works were ready to execute private orders, their prosper-

ity was chiefly dependent on the patronage of Louis XIV.; and when, on account of the pecuniary embarrassments of the crown after the year 1694, this patronage was withdrawn, all the skilled workmen had to be dismissed. After the peace of Ryswick (1697) the Gobelins was opened again, but the operations were restricted to the manufacture of tapestry, which was generally made only for presentation to crowned heads and persons of distinction. The revolution threw the establishment into neglect, and Napoleon gave it little encouragement; but the Bourbons, who returned to the old custom of making gifts with the celebrated tapestry, brought it again into a flourishing condition, in which it remained, with slight interruptions, till it was partly burned by the communists, May 24, 1871.—The manufactory of the Gobelins is now divided into three distinct sections: the dye house, the tapestry workshop, and the carpet factory. The dye house produces not only all different colors, but from 20 to 30 shades of each. While many of the hangings worked 50 years ago are already faded, the factory is now able to produce any color perfectly fast. This great progress is due to the labors of the eminent chemist Chevreul, who was employed by the government to instruct the Gobelins dyers. Large rooms are devoted to the *hautes lisses*, or high warps, upon which the tapestries are suspended as the work goes on. The warp hangs from a horizontal cylinder, and as every yard or thereabout in length is completed, it is wound upon another cylinder in the lower part of the frame. The principal features of the design being traced with white chalk by the artist upon the stretched thread of the warp, he marks, with the aid of tracings from the picture, which he attaches to the warp, the exact positions of the light and dark shades. Then, with the pattern conveniently placed for reference, the artist stations himself against the back of the tapestry, and, with his worsteds and silks at hand, begins to work in the different colors. The vertical threads of the warp are divided by a heddle or cross stick which keeps half of them in advance of the rest; but those behind can be brought forward whenever required by means of small cords, one of which is attached to each warp thread. The left hand is introduced between the two sets of threads, taking up as many as need be, and through these the needle is passed from left to right. The thread when stretched is piled with the point of the needle, and is then passed back in the contrary direction through the space opened by shifting the position of the front and back threads. By ingeniously combining the woofs, the colors are made to blend perfectly, and effects are obtained like those of painting. The work is so slowly executed that an artist is not expected to average in a year a production of more than about 39 inches square.—In 1826 the manufactory of carpets, called *la savonnerie*, from an old soap factory in which the making

of carpets had been carried on from the year 1615, was connected with the tapestry establishment. The carpets are remarkable for smoothness and evenness of texture and their strength and fineness, excelling even the Persian in these respects. Some of them require from five to ten years for their completion, and cost 60,000 to 150,000 francs. All the carpets made during the reign of Napoleon III. were used for the decoration of the imperial palaces. The largest ever made was manufactured for the gallery of the Louvre. It consists of 72 pieces, the total length being more than 1,300 ft.—Among the celebrated pieces executed at this establishment is a picture, completed about the year 1844, of the "Massacre of the Mamelukes," after the celebrated work of Horace Vernet, which has been presented to the queen of England. The portrait of Louis XIV., by Rigaud, is considered the finest work of the Gobelins. Titian's "Assumption" was worked after a copy by Serrur into a magnificent tapestry 21 ft. high.

**GOBERT**, Napoléon, baron, a French philanthropist, born in 1807, died in Cairo, Egypt, in 1833. He was the son of a general, and godson of Napoleon. He served in the army without distinction. By his will the French academy and the academy of inscriptions were made his residuary legatees, on condition that the former should award nine tenths of the income of its share of the legacy as a prize to the author of the most eloquent work on French history that had appeared during the year preceding the distribution, and one tenth to the next in merit; and that the academy of inscriptions should award similar prizes to the authors of the first and second most learned and profound works on the history of France; this income to be paid annually to the recipients until better works of the same kind should appear. The heirs unsuccessfully contested the bequest, but the academies compounded with them, and secured an income of 10,000 francs each, which has since 1840 been disposed of in accordance with the will.

**GOBI** (Mongol, a desert), an immense tract of country in central Asia, occupying mainly the table land between the Altai mountains on the north and the Kuenlun on the south, between lat. 37° and 50° N., and lon. 80° and 120° E. It is about 1,800 m. long, with an average breadth of nearly 350 m., though in some parts it is much greater; area, about 600,000 sq. m. It is divided into two nearly equal parts, the western being comprehended in Turkistan, the eastern in Mongolia, a small part being in the Chinese province of Kansu, and reaching to the Chinese wall. Of the western part little is known; the surface consists mainly of fine loose sand, which is drifted about by the winds, and sand storms are of frequent occurrence. It is drained by the Yarkand or Daria, which falls into Lake Lob; this lake has no outlet, and is consequently brackish. Similar salt lakes are numerous

throughout the desert; and upon these and the rivers which flow into them the Tartars pitch their tents and raise their cattle. The eastern part is somewhat better known; there are a few fertile valleys and some towns; but a large part, called by the Chinese Shamo, or the Sand sea, is a plain 2,500 to 3,000 ft. above the sea, covered with gravel and small stones. Pasturage is the usual occupation of the Mongolians, who lead a nomadic life in the mountain fringes of E. Gobi. It is drained toward the east by the head waters of the Amoor, which falls into the sea of Okhotsk, and toward the north by the Selenga, which, bursting through the Altai range, falls into Lake Baikal. The climate of the entire desert is intensely cold during the winter, which lasts nine months.—See Atkinson's "Explorations in Siberia, Mongolia," &c. (1857).

**GOBY**, a spiny-rayed fish, of the genus *gobius* (Linn.), found on the rocky and sandy coasts of the old world. The black goby (*G. niger*, Linn.), the largest on the British coasts, is about 6 in. long; it has two dorsal fins, and the ventrals are united below the throat into a sucking disk by which it can attach itself to the rocks,

Goby (*Gobius niger*).

to which it retires to devour its living prey. Gobies, like the allied blennies, are very tenacious of life, and will live a considerable time out of the water. It was known to the ancients that the goby of the Mediterranean built in the spring a nest, well made of seaweeds, in which the female deposited her eggs, guarded by the male until they were hatched; other species make a similar nest. Gobies are sometimes found in very deep water.

**GODAVERY**, a large river of British India, rising in the Western Ghats, about 60 m. from the Indian ocean, lat. 19° 58' N., lon. 73° 30' E., and, after a S. E. course of 900 m. across the peninsula, flowing into the bay of Bengal by two principal channels. It receives in its course the Manjera from the south, and the Poorna and Wurdah from the north. After the junction of the Wurdah it is a mile wide, and after passing through the mountainous region it becomes 4 m. wide. The delta commences at Pechakalunka, in lat. 16° 57' N., lon. 81° 49' E., and contains an area of 500 sq. m. The banks of the river on each side are marked by ridges a few feet high, formed by deposits during the inundation. From Coringa, at its principal mouth, the navigation was until recently

practicable only for vessels drawing not more than 3 ft., and at Sinteral, about 140 m. up the river, were several barriers. A dam now stretches across the Godavery above one of these barriers, nearly a mile long, and from 10 to 12 ft. wide. A canal is thus formed about 26 m. long, which is provided with double locks 200 ft. long and 25 ft. wide. At Enchapully is a barrier of rocks, and the river becomes very tortuous; here another dam has been formed of loose stones, 3,600 ft. long and 12 to 24 ft. high, and a canal was made to connect it with the lower level. By these means the river is open for navigation up to the Wurdah, which can be ascended near to the cotton mart of Umrawutty. The completion of these works has given a strong impulse to the progress of the country. As early as 1846 the East India company began their construction, but the outbreak of the mutiny in 1857 checked the work for a long time. In 1863 the work was resumed, and the river, formerly navigable only for small craft and during the rainy season, now carries large ships and steamboats far inland.

**GODDARD, Arabella**, an English pianist, born at St. Servan, near St. Malo, Brittany, in January, 1836. She very early manifested great musical talent, and was instructed on the piano by Kalkbrenner in Paris, and, after the removal of her parents to London in 1848, by Mrs. Anderson, pianist to the queen, and Thalberg. Her first public appearance was at a concert in her father's residence, March 30, 1850; and in October she played at the grand national concerts, becoming known as a brilliant performer of the music of Thalberg and the modern romantic school. Subsequently she studied harmony with Macfarren, and has played more classical music. In 1854-'6 she gave concerts in the principal cities of France, Germany, and Italy. In 1860 she was married to Mr. Davison, a musical critic, but still retains professionally her maiden name. In 1872 she visited the United States and played at the great musical festival in Boston.

**GODERICH**, a town, port of entry, and the capital of Huron co., Ontario, Canada, on the E. shore of Lake Huron, at the mouth of the Maitland river, and at the terminus of the Buffalo and Goderich branch of the Grand Trunk railway, 118 m. W. of Toronto; pop. in 1871, 3,954. The surrounding country is fertile and picturesque, and the town is much frequented in summer for the cool air from the lake. It has a good harbor, protected by a pier, and is furnished with a lighthouse. Daily lines of steamers run to Sarnia, Detroit, and ports on the lake. The fisheries are valuable. The town is celebrated for its salt wells, of which eight are in operation. It also contains a large grain elevator, manufactories of woollens, iron castings, machinery, leather, boots and shoes, wooden ware, &c., several saw and grist mills, two branch banks, two weekly newspapers, and churches of four denominations.

**GODERICH, Viscount**. See RYON, earl of.

**GODFREY, Thomas**, an American mathematician, born in Philadelphia, died in December, 1749. He had but a common education, and followed the business of a glazier in his native city; but he mastered all the books on mathematics that he could obtain, and learned Latin to read mathematical works in that language. He borrowed a copy of Newton's *Principia* from James Logan, secretary of the commonwealth, and in 1730 communicated to him an improvement that he had made in Davis's quadrant. In 1732 Logan gave an account of the invention to Edmund Hadley of England, and Godfrey also prepared a description of it addressed to the royal society of London, but did not send it, awaiting the effect of the letter to Hadley. No answer was received after an interval of a year and a half, and then the invention of Godfrey was laid before the royal society by the botanist Peter Collinson. Meantime, in 1731, Mr. Hadley had presented a paper containing a full description of an improvement of the quadrant similar to that of Godfrey. The rival claims were investigated by the royal society, and it was decided that they were both entitled to the honor of the invention, and a reward of £200 was bestowed on Godfrey, in household furniture instead of money, on account of his intemperate habits. Godfrey's or Hadley's quadrant is the same in principle and application as the sextant.

**GODFREY OF BOUILLON**. See BOUILLON.

**GODIVA**. See COVENTRY.

**GODKIN, Edward Laurence**, an American journalist, born at Moyne, county Wicklow, Ireland, Oct. 2, 1831. He was educated at Queen's college, Belfast, and during the Crimean war (1854-'6) was correspondent in Turkey and Russia of the London "Daily News." In 1856 he came to the United States, and made a journey on horseback through the southern states, which he described in a series of letters to the "Daily News." He then studied law in New York, and was admitted to the bar in 1858, but has never practised. In 1862 he was again employed as correspondent of the "Daily News," and was also a writer of leading articles for the "New York Times." In July, 1865, he became editor of "The Nation," and since 1866 has also been its proprietor.

**GODMAN, John D.**, an American naturalist, born in Annapolis, Md., Dec. 20, 1794, died in Germantown, Pa., April 17, 1830. He was apprenticed to a printer in Baltimore, but at the age of 20 enlisted in the navy and was present at the defence of Fort M'Henry. After the war he studied medicine, and practised till 1821, when he became professor in the medical college of Ohio at Cincinnati, and commenced there the "Western Quarterly Reporter." In 1822 he removed to Philadelphia and devoted himself to the science of anatomy, of which in 1826 he became professor in Rutgers medical school, New York; but he soon resigned and went to the West Indies for his health, and on his return settled in German-

town. He prepared the zoölogical articles for the "Encyclopædia Americana" as far as the end of the letter C, and contributed to various scientific periodicals. His principal work is his "American Natural History" (3 vols. 8vo, Philadelphia, 1823-'8), besides which he published an "Account of some Irregularities of Structure and Morbid Anatomy," "Bell's Anatomy," with notes, "Anatomical Investigations," and "Rambles of a Naturalist."

**GODOLPHIN, Sidney**, earl of, an English statesman, born in Cornwall about 1635, died Sept. 5, 1712. Soon after the restoration of the monarchy he was made one of the grooms of the bedchamber to Charles II., was elected member of parliament in 1661, and became privy councillor in 1679. He voted for the exclusion of the duke of York from the throne in 1680, was made first commissioner of the treasury in 1684, and after the accession of James II. was retained in office as chamberlain to the queen, and became one of the chief royal advisers. He took office under William III., having become an almost indispensable part of the machinery of state, was placed at the head of the treasury, and on the accession of Queen Anne in 1702 was created lord high treasurer, being the first person who had held that office since the revolution. He was, however, led by Marlborough to doubt the stability of the government created by the revolution, and he served it for six years while at the same time sending professions of attachment and promises of service to James. In 1706 he was created Viscount Rialton and earl of Godolphin, attached himself to the whig party, and the final result of his struggle with Harley for the premiership was his sudden and rude dismissal from office in 1710. Godolphin was the most prudent and experienced of the financiers of his time. "Every government, therefore," says Macaulay, "found him a useful servant; and there was nothing in his opinions or in his character to prevent him from serving any government." He was a keen gambler and horse racer.

**GODOY, Manuel de**, a Spanish statesman, born in Badajoz, May 12, 1767, died in Paris in October, 1851. Descended from an old and noble family, yet poor, he went to Madrid at the age of 17 to seek his fortune. He entered the military service, and his handsome figure, amiable character, and elegant manners soon attracted the notice first of the ladies of the court, then of the queen, and next of the king. His talent for intrigue gained him rapid advancement, and he was successively created duke of Alcudia, generalissimo of the land forces, grand admiral of Spain and of the Indies, secretary of state, prime minister to succeed Aranda in 1792, knight of the golden fleece, and a grandee of Spain of the first class. When Louis XVI. was brought to trial by the convention, Godoy declared war against France; but by the treaty of Basel in 1795 Spain formed an alliance with the republic. For this service Charles IV. gave

him the title of "prince of the peace," and a domain which yielded him a large revenue. In 1797 he married Maria Theresa de Bourbon, niece of the king, although it is alleged that he was already secretly married to Josephine Tudo, the daughter of a military officer. Obligated in 1798 to resign his power for a time, he resumed it in 1801, when he signed the treaty of Badajoz, which proposed to partition Portugal between France and Spain, and which by a secret article gave to himself more than \$3,000,000. During his ministry the Spanish possession of Louisiana was transferred to France. In the height of his power, however, he incurred the enmity of the nobles by his preponderance in the government, of the priests by his opposition to the inquisition, and of the people, who attributed to him all the political evils they endured; and soon a strong party was formed against him under the patronage of the prince of Asturias, afterward Ferdinand VII. When Napoleon determined upon the dethronement of the Bourbons of Spain, and at the same time a criminal suit instigated by the prince of Asturias was pending against Godoy, the latter advised the royal family to take refuge in America. This project was not matured when an insurrection broke out against Godoy, who was seized by the populace in his hotel, and his life having been with difficulty saved, he was held prisoner to await the course of justice. Napoleon however, who wished to avail himself of his influence over Charles IV. to secure the renunciation of the crown of Spain by that monarch, obtained his freedom, and invited him to the conferences of Bayonne (1808). Godoy drew up the act of abdication signed by the king, whom he then accompanied in his exile to Rome; and his immense possessions in Spain were confiscated. Godoy lived in Paris after the death of Charles IV., and received a pension of 5,000 francs from Louis Philippe, although in 1842 he was reinstated in his dignities in Spain. His "Memoirs," of which he was only nominally the author, appeared in Madrid, Paris, and London in 1836.

**GODUNOFF, Boris Fedorovitch**, a czar of Russia, born in 1552, died in 1605. He was a brother-in-law of the czar Feodor I., whose infirmities of body and mind enabled Godunoff to obtain complete control of the government. He aspired to the throne, and had most of his rivals put to death or exiled. Among his victims was Demetrius, the younger brother of Feodor and heir to the crown, who was banished to Uglitch, where he died by violence in 1591. On the death of Feodor, in 1598, Godunoff succeeded to the throne, mainly through the aid of the patriarch of Moscow, the head of the national church. He sought to distinguish his reign by various reforms and by promoting education, and to dazzle the people by magnificent monuments. Great disaffection arose in the empire, and in 1604 a pretender claiming to be Demetrius appeared from Poland at the head of a consider-

able army. He won a battle at Novgorod, but was signally defeated at Dobrynitch. (See DEMETRIUS.) At this juncture Godunoff suddenly died, and his death was popularly ascribed to poison administered by himself. His son and successor, Feodor, perished soon after. Russian historians generally consider Godunoff as a usurper; but the house of Romanoff regard him as a legitimate sovereign.

**GODWIN**, earl of Wessex, a Saxon noble, born about the end of the 10th century, died in April, 1053. He was a cowherd, but having ingratiated himself with Ulfr, the brother-in-law of King Canute, he received in marriage the daughter of that chieftain, and became the most powerful nobleman in England. In the interest of Harold Harefoot he was believed to have procured the murder of Prince Alfred; but he was pardoned both by Hardicanute and Edward the Confessor, Alfred's brothers, and exerted himself to secure the crown for the latter. He afterward rebelled against Edward, by refusing to punish arbitrarily the men of Dover for the riot against Earl Eustace, and was obliged to flee the kingdom; but returning with a body of troops, he compelled the king to restore his possessions and dignities. Within a year after his restoration Godwin died. The Norman historians relate that he stood up at the king's banquet to aver his innocence of the death of Alfred, but fell speechless to the earth, and died soon after. He was the father of Harold, the last Saxon king.

**GODWIN, George**, an English architect and author, born at Brompton, Middlesex, Jan. 28, 1815. He was instrumental in founding the London art union in 1836-'7, of which in 1839 he was made chief honorary secretary; and to the "Art Union Magazine," now the "Art Journal," he became a constant contributor after its establishment in 1839. In 1844, having previously published "The Churches of London," he became editor of the "Builder." His chief architectural works are St. Mary's church, West Brompton, and the restoration of the church of St. Mary Redcliff, Bristol. He has published "Churches of London" (1838), "Facts and Fancies" (1844), "History in Ruins" (1853), "London Shadows" (1854), "Buildings and Monuments," "Town Swamps and London Bridges" (1859), "Memorials for Workers," and "Another Blow for Life" (1864). He has also written several dramas.

**GODWIN, Parke**, an American journalist, born in Paterson, N. J., Feb. 25, 1816. He graduated at Princeton college in 1834, studied law, and was admitted to the bar in Kentucky, but did not practise. From 1837 to 1843 he was an editorial contributor to the New York "Evening Post," edited by his father-in-law, William Cullen Bryant; and in February, 1843, he began a literary and political weekly journal, "The Pathfinder," which he continued three months, when he resumed his connection with the "Evening Post." In February, 1843, he advocated free trade in a public de-

bate in New York with Horace Greeley and others. In 1844 he published "A Popular View of the Doctrines of Charles Fourier," and a treatise on Fourier's ideas of industrial association, entitled "Democracy, Pacific and Constructive." In 1845 he was appointed a deputy collector in the New York custom house. For some years he was a frequent contributor to the "Democratic Review," several of his papers advocating important reforms which were subsequently carried out in the revision of the constitution and code of the state of New York. In 1852 he made an extended tour in Europe. In 1853 he became one of the editors of "Putnam's Monthly Magazine," to both the first and second series of which (1853-'7 and 1867-'70) he was a frequent contributor; and two collections of his articles have been reprinted in volumes, "Political Essays" (12mo, 1856), and "Out of the Past," critical and literary papers (1870). In 1860 he published the first volume of a "History of France," embracing ancient Gaul, and terminating with the era of Charlemagne. Since 1860 Mr. Godwin has made two protracted visits to Europe, during which he prosecuted his researches in French history. In addition to the publications above enumerated, he has written "Vala, a Mythological Tale," founded upon incidents in the life of Jenny Lind (1851); translated a part of Goethe's autobiography and a volume of Zschokke's tales, and compiled a "Handbook of Universal Biography" (1851; new ed., "Cyclopædia of Biography," 1865). He is now (1874) preparing "The History and Organization of Labor," a volume on "The Nineteenth Century, with its Leading Men and Movements," and "A Winter Harvest," a book of European travels. Until recently he was managing editor of the "Evening Post."

**GODWIN, I. William**, an English author, born at Wisbeach, Cambridgeshire, March 3, 1756, died in London, April 7, 1836. He was the son of a dissenting clergyman, was educated in the dissenting college at Hoxton, and in 1778 became minister of a congregation at Stowmarket, Suffolk. At the end of five years the incompatibility of this occupation with the new moral and political theories he had begun to entertain induced him to sever his connection with the ministry, and going to London he thenceforth devoted himself to literature. He soon began to promulgate doctrines which, if carried out, would have subverted the whole structure of society. Having already acquired some reputation by his "Sketches of History" (London, 1784) and contributions to the "Annual Register," of which he was at one time the principal conductor, he published the "Inquiry concerning Political Justice, and its Influence on General Virtue and Happiness" (2 vols. 4to, 1793), in which an intellectual republic, founded upon universal benevolence, is advocated with persuasive eloquence. In 1794 he appeared in the political arena as the champion of Horne Tooke, Thelwall, Hardy, and

others, who had been brought to trial on a charge of treason. In the same year appeared his most remarkable work, "Caleb Williams," a novel designed to illustrate some of the peculiar views put forth in the "Inquiry concerning Political Justice;" but the interest of the story is so predominant that the social object of the author was entirely overlooked. In 1796 he made the acquaintance of Mary Wollstonecraft, author of the "Vindication of the Rights of Woman," and, in accordance with the views held by both of them respecting marriage, cohabited with her for six months, when for prudential reasons they were married. His wife died after giving birth to a daughter, who became the second wife of the poet Shelley. His "Memoirs of the Author of the Vindication of the Rights of Woman" (1798) is a feeling tribute to her memory, but describes the details of her life with a minuteness which subjected him to considerable censure. In 1799 appeared "St. Leon," containing many incredible situations, but also many passages of splendid description and true pathos; it purports to be the autobiography of a philosopher who has become immortal by the discovery of the elixir of life. On this and "Caleb Williams" his reputation chiefly rests. His other novels are "Fleetwood" (1805), "Mandeville" (1817), "Cloudesley" (1830), and "Deloraine" (1833). Among his other works were the tragedies "Antonio" (1800), and "Faulkner" (1807-'8); a "Life of Chaucer" (2 vols. 4to, 1803); "Lives of John and Edward Phillips, Nephews of Milton" (4to, 1815); and a "History of the Commonwealth" (4 vols. 8vo, 1824-'8), written with great impartiality, and valuable as a repository of facts. His last important work, "Thoughts on Man, his Nature, Productions, and Discoveries" (1831), was a series of essays in the style of his earlier writings. A posthumous work by him, "The Genius of Christianity Unveiled," was published in 1873. For some years he carried on business as a bookseller, and under the name of Edward Baldwin published a number of children's books, small histories, and other compilations, some of which were by himself. In the latter part of his life he obtained a clerkship in the record office. His "Autobiography, Memoirs, and Correspondence" was published in 1874. **II. Mary Wollstonecraft**, an English authoress, wife of the preceding, born in Beverley, Yorkshire, April 27, 1759, died in London, Sept. 10, 1797. Her father, a man of ungovernable temper, embittered her childhood by the cruelty with which he treated his family. A natural independence of character induced her to sever herself from such a parent, and upon the death of her mother she established a school at Islington, in the direction of which she was assisted by two of her sisters. The illness of a friend in Lisbon called her thither for a while, and upon her return to England she found her school ruined by mismanagement. After a short experience as a governess in the family of Lord Kingsborough,

she determined to devote herself to a literary life. Having acquired considerable reputation by her "Thoughts on the Education of Daughters," and some works of fiction, as also by translations of Lavater's "Physiognomy" and Salzmann's "Elements of Morality," she ventured in 1791 upon a reply to Burke's "Reflections on the French Revolution," and soon after published her celebrated "Vindication of the Rights of Woman" (1791), in which the claim of woman to share with man the functions he has exclusively exercised is argued with boldness and ability. Full of enthusiasm for the new ideas which the French revolution had inaugurated, she went to Paris, only to find her hopes crushed by the overthrow of the Girondists. She here also formed a connection with an American named Imlay, who deserted her. Giving birth to a child, she endeavored to put an end to her existence, and afterward sought relief from her troubles in writing her "Letters from Sweden, Norway, and Denmark" (1796), which she had visited while she had her home in Paris. In 1797 she was married to William Godwin, and she died in childbirth. Her posthumous works were published by her husband (4 vols. 12mo, 1798).

**GODWIT**, a bird belonging to the *scolopacidae*, or snipe family, and subfamily *limosinae*, which includes also the curlew. It forms the genus *limosa* (Briss.), characterized by a long slender bill, inclined a little upward and slightly thickened at the tip, with sides compressed and grooved on both mandibles for nearly the whole length; the upper mandible a little the longer, and the gape moderate; wings long and pointed, the first quill the longest; tail short and even; tarsi slender, longer than the middle toe; toes long, the outer united to the middle by a membrane as far as the first joint; hind toe partly resting on the ground; claws short and obtuse. The shape is more slender and the bill and legs longer than those of the snipes. They are shy birds, frequenting the seashore, living chiefly on worms which they draw from the mud; they are found in most parts of the world, though most abundantly in cold climates, and their habits and manners are like those of the curlew; the flesh is excellent eating. The marbled godwit of the United States (*L. fedoa*, Linn.) is, in the female, about 20 in. long to the end of the tail, the bill  $4\frac{1}{2}$ , tarsus 3, and wing 9 in.; the male is somewhat smaller. The general color above is brownish black variegated with pale reddish, the former in bands and the latter in spots; below pale rufous, with transverse brownish black lines on the breast and sides; primaries dark brown on their outer webs, light rufous on the inner; tail light rufous, with brownish black bars; bill dark at the end, dull flesh color toward the base. It is found over the temperate regions of North America, and in South America; it is abundant in Florida during the winter, going to the north to breed in spring, and returning about the last of Au-

gust within the limits of the United States. It is a shore bird, rarely seen many miles inland; when feeding it probes the mud with its long bill, plunging it in often for its whole length, in search of marine worms and small crustaceans. Its flight is quick and regular, in long and fre-

Marbled Godwit (*Limosa fedoa*).

quently changing lines.—The Hudsonian godwit, a smaller and much rarer American species (*L. Hudsonica*, Lath.), is about 15 in. long, with an extent of wings of 28 in., tail 3, bill a little over 3, and tarsus  $2\frac{1}{2}$  in.; weight about 9 oz. In the adults, the prevailing color above is brownish black, with spots and transverse bars of pale reddish; upper tail coverts white; beneath, yellowish red, with transverse bars of brownish black, and sometimes the feathers tipped with white on the abdomen; tail black, white at the base and tipped with the same; under wing coverts black; shafts of primaries white. The young are cinereous above, with irregular brownish black marks, dull yellowish

Hudsonian Godwit (*Limosa Hudsonica*).

white below, upper tail coverts white, tail as in adult. It is abundant in the northern parts of this continent, but rare in the United States, and scarcely seen south of New Jersey except in winter; it breeds in the far north; the females are somewhat larger than the males.—

The common godwit of Europe (*L. Lapponica*, Linn.), in its winter plumage, is deep brownish gray, the feathers edged with whitish; the breast brown gray, whitish underneath; rump white, radiated with brown; in summer the prevailing color is reddish.

**GOENTOER**, a volcano of Java, about 100 m. S. E. of Batavia, nearly 7,000 ft. high. It is active, and produces considerable damage by periodical eruptions, four of which (1818-'41) were especially violent, destroying a vast number of coffee trees, and covering large tracts with heaps of stones, ashes, and sand.

**GOERTZ**. See GÖRTZ.

**GOES**, a town of Holland, on the island of S. Beveland, 15 m. W. of Bergen-op-Zoom; pop. in 1867, 6,313. It is surrounded by walls, and contains a number of squares, of which the Groote Markt, the largest, is planted with trees. The public buildings are the town hall, a Roman Catholic and a Protestant church, a new corn exchange, and many schools and charitable institutions. Both the old and new harbors are defended by forts, and there is an active commerce.

**GOES, Hugo van der**, a Flemish painter, pupil and successor of Van Eyck, flourished in the second half of the 15th century. His paintings are all of religious subjects, and their chief excellence is the grace and dignity of the countenances. His masterpiece is a "Crucifixion" in the church of St. James at Bruges. This picture was preserved from the general destruction of church ornaments in the 16th century by being coated with dark clay on which the ten commandments were inscribed.

**GOETHE, Johann Wolfgang von**, a German author, born in Frankfurt-on-the-Main, Aug. 28, 1749, died in Weimar, March 22, 1832. His father, Johann Kaspar Goethe, the son of a tailor of Frankfurt, had raised himself to the dignity of an imperial councillor, and in 1748 had married Katharina Elisabeth, daughter of Johann Wolfgang Textor, the chief magistrate of the city. Their first offspring, the subject of this article, inherited the best qualities of both parents. The father, a cold, stern, formal, and pedantic man, was a person of vigorous mind and of rigid will; and the mother was a simple-hearted, genial, vivacious, and affectionate woman, who loved poetry and the romantic lore of the nursery. In one of his poems Goethe afterward said: "From my father I derive my frame and the steady guidance of my life, and from my dear little mother my happy disposition and love of story-telling." But he derived a great deal more from both; for the father, rigid disciplinarian as he was, early indoctrinated him in the knowledge of the classics and modern languages, and in the love of fine art; while the mother gave him, besides her vivacity and animal spirits, that large and instinctive wisdom which comes of broad human sympathies. Goethe was a precocious child, handsome, lively, and sensitive. His early education was wholly domestic, in the

company of his only sister Cornelia, to whom he was passionately attached. Before he was ten years of age he wrote several languages, meditated poems, invented stories, and had a considerable familiarity with works of art. Frankfort was a mediæval city, full of old associations and the remains of antique customs, but just beginning to stir with the quick movements of a more modern trade and industry. None of its influences, old or new, were lost upon the child, whose position in middle life, while it brought him in contact with the most cultivated men of society, did not exempt him from occasional mixture with the lower orders, or from the ruder experiences of life. His first love for Gretchen, a girl in the humblest ranks, began amid a circle of forgers and delinquents. In October, 1765, at the age of 16, he was sent to Leipsic to begin his collegiate studies. His autobiography passes over this part of his life with a few words, but other evidences show that it was a time not of hard and varied study merely, but of much wild and frolicsome adventure. While he mastered with an easy grace the manifold sciences and arts of a German university, jurisprudence, medicine, logic, rhetoric, philosophy, morals, drawing, &c., he was no less at home in those wayward and capricious sports, in the love-makings and the merry-makings, which are natural to this period of life. No criminal indulgences are charged upon him, but he lived freely and buoyantly, preferring often the society of jovial companions, free thinkers and actors, to that of the more accepted respectabilities of a staid literary metropolis. He had already fallen into the habit of turning his inward feelings into verse, and two dramas, *Die Lärne des Verliebten* and *Die Mitschuldigen*, grew out of his more erratic impulses. After a brief interval passed in sickness at home, during which he read the books of the alchemists, he was transferred in 1770 to the university of Strasburg, where he renewed his studies of jurisprudence and the natural sciences, enlarged the number of his acquaintances, including Herder and Jung-Stilling, and fell in love with the daughter of a dancing master. Herder's friendship was of the greatest use to him, as it introduced him to the reading of Shakespeare, Goldsmith, and other English classics, and awakened within him a profounder sense of the grand poetry of the Hebrew Scriptures. He had fallen in with the family of a clergyman at Sesenheim, where there were two daughters, with one of whom, Frederika, he became enamored, and they were finally betrothed; but in leaving the university in 1771, he tore himself away from the bond and the attachment. Impetuous and headlong as he was, there was already a tendency in him to value external objects, human and others, as they assisted in that deep and varied culture which he began to make the principal aim of his existence. In 1772 he went to Wetzlar to practise law, and in the following year published a play destined to attract public atten-

tion toward him, and to give the world its earliest glimpses of his extraordinary genius. This was *Götz von Berlichingen*, a dramatic version of the story of Götz of the Iron Hand, an old predatory burgrave of the 16th century, who made war upon his fellow barons, sometimes to increase his own store, and sometimes in defence of the poor. His lawless career represented the sturdy struggle of feudalism against an advancing civilization, and Goethe seized the incidents to present them in a clear, powerful, picturesque, and dramatic whole. This work was the outbreak of a genius as rude and stalwart almost as Götz himself, asserting its freedom against the fetters of an artificial literary spirit; one of the earliest throes in that period of intellectual convulsion in Germany which has taken the name of the *Sturm- und Drangperiode*, or storm and pressure period. It excited the greatest enthusiasm in the literary world, and romantic dramas for a time became the fashion. In the interval Goethe had passed the time in wandering through the Rhine country. At Wetzlar he again fell in love, but as the object of his love, Charlotte Buff, was betrothed to one Kestner, to whom she was soon after married, the affection was not returned. A young student named Jerusalem, with whom Goethe was intimate, having committed suicide because of a similar unhappy passion for the wife of one of his friends, Goethe wove the incidents of the two cases into a novel, which he called *Die Leiden des jungen Werther* (1774), known in English as "The Sorrows of Werther." The sensation produced by it was prodigious. The most distinguished literary men praised it as a profoundly philosophic romance, while the common people were carried away by its eloquence and pathos. Its chief success, however, arose from the fact that it expressed a certain sad longing and discontent which was then a characteristic of the age. The same year he wrote *Clavijo*, a drama founded on Beaumarchais's memoir on Clavijo, projected a drama on Mohammed, another on Prometheus, only a few lines of either of which were written, and already revolved in his mind the drama of *Faust*. Two love engagements, one with Anna Sibylla Münch, and the other with Anna Elisabeth Schönmann, immortalized in his works under the name of Lili, diversified the experiences of this period. The fame acquired by *Werther* brought Goethe under the notice of Charles Augustus, grand duke of Saxe-Weimar, who in 1775 invited the poet to spend a few weeks at his court. Goethe went there, and the result of the friendship thus contracted was that Goethe thereafter made Weimar his permanent residence. He was created a *Geheimer Legationsrath*, or privy councillor of legation, at a salary of 1,200 thalers per annum; but his principal public occupation seems to have been to superintend the artistic pleasures of the court. Weimar was a small city, without trade or manufactures, but made up for its want of

commercial activity by its varied literary culture. It was filled with notabilities, among whom are to be noticed particularly Wieland, Herder, Musäus, Knebel, Seckendorf, Corona Schröter, the dowager duchess Amalia, Frau von Stein, and afterward Schiller. In this circle Goethe at once took his place as the presiding deity. "He rose like a star in the heavens," says Knebel; "everybody worshipped him, and especially the women." His first years there were spent in wild and tumultuous enjoyments, in which "affairs of the heart" did not always end with the heart. But Goethe's nature was too profound, his intellectual activity too great, to be long beguiled by the frivolities of masking, hunting, drinking, dancing, and dicing, and he resumed his more serious pursuits. The first fruit of his return (1779) was *Iphigenie auf Tauris*, a prose drama, which he afterward turned into a beautiful drama in verse. After a visit to Switzerland the same year, described in his *Briefe aus der Schweiz*, he composed a little opera, called *Jery und Bätely*, full of Swiss inspirations. He also began to devote himself strenuously to the study of natural science, in which he became a proficient. The novel of *Wilhelm Meister* was at the same time in progress, and many of his best small poems were produced at this period (1780-'83). In 1786 he made a journey to Italy, where he passed nearly two years in the most laborious study of its antiquities and arts, and in the composition of *Torquato Tasso*, a drama suggested by the life of that poet at the court of Ferrara. He was so absorbed in the past of Italy that he paid little attention to its present condition or people. The narrative of his travels, *Die italienische Reise*, contains the most charming descriptions of the scenes through which he passed. On his return to Weimar in 1788, he published *Egmont*, a romantic drama, full of passion and interest, representing a sombre and tragic episode in the revolution of the Netherlands, but in which he has not confined himself at all to the incidents of actual history; the character of Clärchen is by many regarded as one of his most successful female creations. A relation with Frau von Stein, which Goethe had long maintained, was now broken off, but he soon formed another with Christiane Vulpius. She was uneducated, and lived in some domestic capacity in his house; but Goethe afterward married her, to legitimate his son (born Dec. 25, 1788, died Oct. 27, 1830). In 1792 he accompanied the army of the king of Prussia and the duke of Brunswick in their campaign into France, of which he wrote an account. Soon after appeared his metrical version of *Reinecke Fuchs*. The results of his scientific studies appeared in his *Beiträge zur Optik* and his *Farbenlehre*, in the latter of which he had the hardihood to question the correctness of the Newtonian theory of colors. He wrote also on the metamorphosis of plants, and on topics of comparative anatomy. In all these he displayed a re-

markable penetration and sagacity, and his remarks on the morphology of plants are now reckoned among the earlier enunciations of the theory of evolution. His acquaintance with Schiller, who divided with him the suffrages of the poetic German world, began at Jena in 1794; and though their intercourse was cold at first, it ripened into one of the most enduring and beautiful friendships recorded in literary annals. Schiller's influence upon him was both stimulating and ennobling, and from this time forth we find him engaged in producing his grandest works. The first part of *Wilhelm Meister* (the *Lehrjahre*) appeared in 1795. *Hermann und Dorothea*, a pastoral poem in hexameters, the most perfect of his minor productions, was written in 1797; the *Achilleis* was executed the same year; and he engaged in friendly rivalry with Schiller in bringing forth a series of ballads, of which Goethe's part, *Die Braut von Corinth*, *Der Zauberlehrling*, *Der Gott und die Bajadere*, and *Die Schatzgräber*, are among the masterpieces of German literature. Even these, however, were only the preludes of what he was destined to do; for the *Faust* was still revolving itself in his thoughts, and the *Wilhelm Meister* went steadily forward. At last, in 1805, the great work of his life saw the light. The legend of Faust had been familiar to him as a child, he had thought of it and labored upon it during the whole of his youth, and now in the ripeness of his manhood it had taken its final shape. "It appeals to all minds with the irresistible fascination of an eternal problem, and with the charm of endless variety. It has every element—wit, pathos, wisdom, buffoonery, mystery, melody, reverence, doubt, magic, and irony; not a chord of the lyre is unstrung, not a fibre of the heart untouched." This work raised Goethe to the highest pinnacle of fame, and he was universally acknowledged to be the first poet of his age. If Goethe had died in 1806, he would have achieved a greater renown than any other modern man of letters; but he was destined to live 26 years longer, years of contentment, labor, productiveness, and honor. The stormy and errant impulses of his youth had been subdued; he had mastered himself and his circumstances; the great problem of life, which had filled him with strife and impatience, lay clear before him; his circumstances were easy; and his position at the head of German literature, which he had himself brought out of chaos or formalism into orderly vigor, gained him the homage of Europe. Schiller and other friends were dead; others again, friends of earlier days, were separated from him in sympathy by the large strides which his intellect had made in various paths of thought; and a sombre hue fell upon, without clouding, the serenity of his later years. Moreover, the external events of the world were full of trouble and agitation. It was the era of Napoleon's conquests. Germany palpitated with the rest of Europe in throbs of

war; and the grand duke of Weimar was drawn into the very vortex of commotion. On Oct. 14, 1806, the battle of Jena was fought, and Goethe heard in his calm home the reports of the cannonades. Soon that home was invaded; the French troops entered his house, ransacked his cellars, penetrated even to his bedchamber, and, though they treated him with respect, filled his soul with indignation and wrath. Goethe had all his life been averse to the disturbing influence of politics. His impassiveness under the tempestuous influences of the time had brought upon him the reproach of want of patriotism and of indifference to the welfare of humanity. But when the French approached Weimar, and Napoleon exhibited his spite against Charles Augustus for his active sympathy with his countrymen and allies, the long-pent feeling of the poet burst forth. "Misfortune!" he exclaimed to Falk; "what is misfortune? This is misfortune, that a prince should be compelled to endure such things from foreigners. And if it came to the same pass with him as with his ancestor, Duke John, if his ruin were certain and irretrievable, let not this dismay us; we will take our staff in our hand and accompany our master in adversity as old Lucas Cranach did; we will never forsake him. The women and the children, when they meet us in the villages, will cast down their eyes and weep, and say to one another, 'That is old Goethe and the former duke of Weimar, whom the French emperor drove from his throne because he was so true to his friends in misfortune; because he visited his uncle on his deathbed; because he would not let his old comrades and brothers in arms starve.'" "At this," adds Falk, "the tears rolled in streams down his cheeks. After a pause, having recovered himself a little, he continued: 'I will sing for bread! I will turn strolling ballad-singer, and put our misfortunes into verse! I will wander into every village and every school wherever the name of Goethe is known; I will chant the dishonor of Germany, and the children shall learn the song of our shame till they are men; and thus they shall sing my master on to his throne again, and yours off his!'" But as the noise of the French cannon withdrew from Weimar, he began to pipe once more in his old peaceful strain. All through the revolutionary tumult, in fact, he took refuge in his studies and scientific experiments. On occasion of an interview with Napoleon he scarcely remembered the enthusiasm with which he had spoken to Falk. Napoleon is reported to have said, *Vous êtes un homme*, and fell to criticising his works, especially *Werther*, which he had read, he said, seven times. Goethe was flattered by the appreciative words of the emperor, was invited to Paris, and afterward was decorated with the cross of the legion of honor. In 1809 Goethe printed the most exceptionable of his novels, the *Wahlverwandtschaften* ("Elective Affinities"), in which the charms and graces of his style are employed in

the description of the impulses which spring from the collision of passion and duty in the relations of marriage. By the title of the book, and in the whole spirit of it, he would represent that sexual affinities follow the same inevitable law as chemical affinities, and that humanity struggles impotently against the dictates of nature. Like all his productions, this was suggested by circumstances in his own experience. The work shocked the moral world, in spite of the beauty with which it was written, and to this day tasks the ingenuity of those of his admirers who seek to defend it from attack. His next volumes were of a less doubtful kind: the ballads *Der Todtenkranz*, *Der getreue Eckart*, and *Die wandelnde Glocke*, the *Dichtung und Wahrheit*, an autobiography, and the *Westöstlicher Divan*, a collection of oriental songs and poems. His studies of science and contemporary literature were meantime never remitted. In 1816 he published an art journal, *Kunst und Alterthum*, to which he contributed largely; and in 1818 the second part of *Wilhelm Meister*, the *Wanderjahre*. In 1825 the jubilee or 50th year of his residence in Weimar was celebrated in a grand public festival. In 1831 the second part of *Faust* appeared, a continuation of the first part, obscure and mystical, but full of passages of rare splendor, profound thought, grotesque humor, and bewitching melody. He supposed himself, and many critics supposed, that under the motley garb of the poem there is a deep significance, although few have succeeded in detecting it, while Goethe's own explanations are arid and unsatisfactory to the last degree. As a dramatic poem it cannot be denied that it was a failure, even if we admit that as an enigma, covering some recondite philosophy, it deserves the closest study. The songs at least, and the lyrical parts, are excellent. The old man had lost vigor, but his feelings were still exuberant, and the singer remained. "If Goethe," said an admirer of his, "everywhere great, is anywhere greatest, it is in his songs and ballads. They are the spontaneous outpourings of his mind in all its moods; a melodious diary of his daily and almost hourly fluctuations of feeling; the breathings of his inward life; the sparkling perennial jets of his momentary affections and thoughts. There is the perpetual freshness and bloom about them of new spring flowers. Even when they seem most trivial, they ring through us like snatches of music. So perfect is the correspondence of form and substance that their charm as a whole defies analysis. It is felt, but cannot be detected. Then, again, how diversified they are! Some as simple as the whimpers of a child; others wild, grotesque, weird, and unearthly; and others again lofty, proud, defiant, like the words of a Titan heaping his scorn upon the gods." One year after the completion of *Faust* Goethe was taken ill of a cold, which turned into a fatal fever. Up to the hour of his death, however, he prosecuted his intellectual pursuits. His last writing was

an essay on the dispute between Geoffroy Saint-Hilaire and Cuvier, on the question of unity of composition in the animal kingdom; and his last words were, "More light." He was then in the 83d year of his age. A seal, with an inscription from one of his own poems, *Ohne Hast, ohne Rast*, sent to him on his birthday in 1831, by 15 Englishmen, had given him great delight, for among the Englishmen who participated in the homage were Wordsworth, Scott, Southey, Wilson, Lockhart, and Carlyle. Goethe was the master spirit, the spokesman, as Carlyle says, of his age, the artist *par excellence* of the 19th century.—The letters of Goethe are among the best illustrations of his character. They are, in the chronological order of the periods covered by their dates, those to friends in Leipsic (published in 1849), to Merck (1835-'47), to Jacobi (1846), to Lavater (1833), to Herder (1858), to Knebel (1851), to Klopstock (1833), to the countess Augusta of Stolberg (1839), to Frau von Stein (1848-'51); his correspondence with Schiller (6 vols., 1828-'9; 2d ed., 1856; translated into English by G. H. Calvert, Boston, 1845), with Zelter (6 vols., 1833-'4), with A. W. von Schlegel (1846), with the baron von Stein (1846), with Nikolaus Meyer (1856), with Döbereiner (1856), with Reinhard (1850), with Grüner (1853), with C. F. L. Schultz (1836), and with the councillor Schultz (1853); *Goethe's Briefe und Aufsätze aus den Jahren 1766-'86* (Weimar, 1856); "Goethe's Correspondence with the Brothers Humboldt, 1795 to 1832," edited by Prof. Brataneck (3 vols., Cracow, 1873); and his *Naturwissenschaftliche Correspondenz* (2 vols., Leipsic, 1874). His "Correspondence with a Child" (Elisabeth or Bettina von Arnim) is not genuine. (See Lewes's "Life of Goethe.") The most important notices by his contemporaries are those of Eckermann, *Gespräche mit Goethe* (Leipsic, 1836; translated into English by Margaret Fuller, Boston, 1839), and Falk, *Goethe aus persönlichem Umgang dargestellt* (Leipsic, 1832). The best biographies are by Viehoff (4 vols., Stuttgart, 1854; 3d ed., 1873), Schäfer (2 vols., Bremen, 1851; 2d ed., 1858), and G. H. Lewes (2 vols., London, 1855; translated into German, Berlin, 1857-'8; new ed., abridged, 1873). Among recent works relating to Goethe are: "Goethe and Mendelssohn," by Karl Mendelssohn (English translation, London, 1872); *Gœthe: ses œuvres expliquées par sa vie*, by A. Mézières (Paris, 1872); and *Les maîtresses de Goethe*, by Henri Blase de Bury (Paris, 1873). Bayard Taylor and Karl Goedike have lives of Goethe in preparation. The oldest complete edition of his works is that of Stuttgart and Tübingen (40 vols., 1827-'31, to which his posthumous works were added, 15 vols., 1833-'4). Subsequent editions are numerous; the best are the latest, published by Cotta (30 vols. 12mo, and 12 vols. 8vo, Stuttgart and Tübingen, 1856-'60). Many of his works have been translated into different languages. Among the best into English are "Götz von Berlichingen," by Walter Scott

(1799); "Wilhelm Meister," by Thomas Carlyle (1824); "Truth and Poetry," by Parke Godwin (1847); and "Hermann and Dorothea," by Miss Ellen Frothingham (1870). Of "Faust" there have been many translations; the best are those of Charles T. Brooks (Boston, 1857), and Bayard Taylor (Boston, 1870-'72). A monument to Goethe, to be executed by Schäfer, and erected in the Thiergarten, Berlin, was commenced in 1873.

**GOFFE, William**, an English regicide, born about 1605, died in Hadley, Mass., in 1679. He was one of the most fervent of the Puritans, was a devoted adherent of Cromwell, one of the best officers of the parliamentary army, and one of the judges who tried Charles I. After the death of the protector and the restoration of the Stuarts he escaped to America, and was in 1660, with his father-in-law Edward Whalley, received with courtesy by Gov. Endicott at Boston. Warrants soon after arrived for their arrest, a price was set on their heads, and Indians as well as English were sent in pursuit of them. They removed from house to house, living in mills, in the clefts of rocks on the seashore, and in caves in the forests. They hid themselves for months in a cavern near New Haven, from which they issued only by night. This retreat was discovered, and they fled successively to Milford, Derby, and Branford. At length they found an asylum in the house of a clergyman at Hadley, where Goffe passed the remaining 15 years of his life. In 1675 the town of Hadley was surprised during a religious service by the Pokanoket Indians under their celebrated chieftain Philip. The inhabitants were about to fall beneath the tomahawk when an old man with a long white beard appeared in the church, rallied the disheartened colonists, disposed them for a charge upon the Indians which he himself led, and put the savages to flight. This was Goffe, who in the moment of victory disappeared again for ever, leaving the colonists in the persuasion that a heavenly messenger had fought for them.

**GOG AND MAGOG.** These names occur unconnected in Genesis and 1 Chronicles as the names of several persons; Magog, in the ethnological table of the former book (ch. x.), being the second son of Japheth, and brother of Gomer and Madai, who are generally considered to represent the Cimmerians and Medes respectively. In Ezekiel Gog and Magog are connectedly used to designate a prince and a people of the north, apparently of the Scythian race. In the book of Revelations the words denote the enemies of Christianity who were doomed to destruction. The two famous effigies in Guildhall, London, known as Gog and Magog, have been from time immemorial the pride of the city. There are various legends relating to them. According to one, they represent the last survivors of a race of giants who infested Britain, and were extirpated by the Trojans who came there soon after the destruction of Troy. They were chained as

porters before the palace gates, and when they died their effigies took their place. Another legend says that one of the giants is Gogmagog, and the other Corineus, a British giant who killed him. The effigies, originally of wickerwork and pasteboard, were borne about in public shows and processions as early as 1415, and probably long before. The present ones, carved in wood, and hollow, were set up in 1708. They stand upon octagonal pedestals, and are 14 ft. high.

**GOGOL, Nikolai**, a Russian author, born about 1809, died in Moscow, March 4, 1852. He is said to have failed as an actor, and afterward to have attempted in vain to obtain a position under the government. Subsequently he published "Evenings at a Farmhouse," a collection of tales and sketches, which met with much favor. His first drama was "The Inspector," in which the corruption and venality of the officials was severely satirized. About 1834 he was appointed professor of history in the university of St. Petersburg. In 1842 he published a novel, "Dead Souls," which has been translated into English under the title of "Home Life in Russia" (London, 1854). It narrates the adventures of a rogue who goes about purchasing the rights of the proprietors to serfs recently dead, whose names have not yet been taken from the rolls, in order to obtain advances from government. This work attained great popularity. He went abroad soon after, and in his "Correspondence" (published in 1847) he eulogized the abuses which he had before satirized. By this he lost the favor which he had won from the liberals. He fell into a state of religious melancholy, and destroyed all his unpublished manuscripts, some of which he said were written under the inspiration of the devil. His complete works, comprising tales, dramas, and poems, have been published in 4 vols. (Moscow, 1862).

**GOGRA**, or *Goghra* (Hindoo, *Gharghara*; the *Sareyu* of Hindoo mythology, and, according to Rennell, the *Agoranis* of Arrian), a river of India, which rises on the frontiers of Thibet, in the Himalayas, at an altitude of about 18,000 ft., flows S. and then S. E., and falls into the Ganges near Chupra, 115 m. below Benares. It is at first a vast torrent, having a descent of 15,500 ft. in 75 m.; but after receiving several affluents, it becomes navigable for vessels of considerable size, the descent diminishing to 12 ft. per mile. Its whole length is about 600 m. At its junction with the Ganges it exceeds that river in depth, breadth, and volume of water.

**GOITACAZES**, an Indian tribe of Brazil, long masters of the region lying between the Rio Capapana or Itapapana and Cape São Thomé, whence they repeatedly repulsed the Portuguese who attempted to settle in those parts. Their only weapon was the bow and arrow, in the use of which they were very skilful. They usually took up their abode in places surrounded by water, their dwellings being cabins made of palm leaves suspended from tree

trunks, serving at the same time as a sort of ambuscade. Father Vasconcellos, a writer of the 17th century, reports that they were a ferocious and cruel people, addicted to eating human flesh. Many of these Indians had nevertheless before his time been baptized as Christians, and lived in villages where their descendants are still found, in the northern portion of the province of Rio de Janeiro, rarely mingling with the whites. Their numbers are considerable, and they are ingenious, skilful, sprightly, and frank when kindly treated, but vindictive, improvident, and intemperate.

**GOITRE**, an elastic swelling on the front and sides of the neck, arising from a hypertrophy of the thyroid gland; it is also called bronchocele and Derbyshire neck. It is generally soft and yielding, and varies in size from that of a nut to a mass surrounding the greater part of the neck, sometimes descending far upon the chest; it is usually slow in its growth, and may increase in either lateral lobe or in the median isthmus; it is accompanied by neither tenderness nor discoloration of the skin, and is generally definitely circumscribed. When of small size it occasions no inconvenience; but when large its weight and pressure upon the trachea, œsophagus, vessels, and nerves cause headache, difficulty of breathing and swallowing, congestion of the brain, with dizziness, lividity of the face, protrusion of the eyes, alteration of the voice, dulness of hearing, obstinate cough, ending in pulmonary disease, and threatening even apoplexy and suffocation. The anatomical character of the disease is the enlargement of the cells of the gland, which are filled with a viscid fluid or with blood; in old cases the tumor may become hard and partly bony. All ages are subject to goitre, but young persons and the female sex are most liable to it; it is also hereditary. Though occasionally sporadic, it is essentially an endemic disease in cold and damp countries, as in the deep valleys of the Alps, where the air is moist, cold, and stagnant; it is most common in mountain valleys of the Alps, the Pyrenees, the Himalaya chain in Asia, the Cordilleras in America, the high regions of Scotland, and the chalky districts of Derbyshire and Nottingham in England. Though often connected with cretinism, it does not appear to be a scrofulous disease; neither is it confined to persons living in poverty and uncleanness, for it is the sad inheritance of many wealthy families. Various causes have been assigned for goitre, but none of them are entirely satisfactory; the most probable are the insufficient illumination by the sun, moisture, and stillness of deep valleys; deleterious emanations from clayey soils; the use of snow water, or that from springs, arising from calcareous formations; the deoxygenation of water from great elevation, or its contact with metallic and organic matters eagerly absorbing oxygen. It seems to be connected rather with the geological than with any other character of a region. Goitre may be distinguished from oth-

er tumors in the neck by its shape, consistence, and general development on both sides. The prognosis in a person advanced in life is unfavorable, but in early life it may be cured. The chief remedy for this disease is iodine, both internally and externally, either alone or combined with potash and iron; the patient should be removed from the infected district to the seashore, and a tonic regimen be pursued. When suffocation is imminent from the pressure of the tumor, relief may be obtained for the time by puncture, the seton, ligatures of the supplying arteries, or by extirpation of the gland; the last three are dangerous to life, and have proved fatal, and the first three may fail even if the patient survive the operations. The usual treatment is simply palliative, iodine with tonics and narcotics. There is a form of goitre not uncommon in anæmic females in the United States and in England, with the symptoms of the Alpine disease, though milder, and relieved by the tonic treatment of anæmia.

**GOLCONDA**, an ancient city and fortress of India, in the native state of Hyderabad or the

Nizam's dominions, 7 m. N. W. of Hyderabad. The fortress stands on a rocky eminence, and is a large and strong edifice. It is now chiefly used as a prison, and as a depository for the treasures of the Nizam. The principal inhabitants and bankers of Hyderabad are also permitted to retain houses in it, to which on any alarm they retire with their money and other valuables. About 600 yards from the fortress are the tombs of the ancient kings of Golconda. Each mausoleum occupies the centre of a large quadrangular platform, which is approached on every side by granite stairs. They are mostly constructed of gray stone, ornamented with stucco and Indian porcelain, whose colors retain all their pristine brilliancy, and on which are engraved in white characters various extracts from the Koran. These mausolea are very numerous, and have a striking and impressive appearance when viewed from a distance. Golconda was formerly renowned for its diamonds, but they were merely cut and polished here, being generally brought from Partcall in the S. part of the Nizam's domin-

Tombs of the Kings, Golconda.

ions. It was anciently the capital of a powerful kingdom of the same name, which arose on the overthrow of the Bahmani empire; but it was taken by Aurungzebe and annexed to that of Delhi.

**GOLD**, a precious metal, ranking the first in beauty and value among useful metals from the earliest times to the present day; distinguished for being the only metal of a yellow color, and for possessing in the highest degree the properties of ductility and malleability. In chemistry its symbol is Au, from the Latin *aurum*, gold; its equivalent number 98.5, or, in the usage of many chemists, the double of this, 197. Its density varies according as the metal is more or less compressed; it is rated when hammered at from 19.258 to 19.4. In a finely

divided state, precipitated from its solution by sulphate of iron, it has proved of specific gravity 20.72. When pure the metal is nearly as soft as lead, and is then susceptible of its greatest extension by beating or wire-drawing. (See **GOLD BEATING**.) In thin leaf it is transparent, and the transmitted light is of a green color; by heat the color is changed to ruby red, and this color the metal finely divided imparts under certain conditions to glass. Its melting point is variously given as 2016° F., 2192°, 2518°, and 2590°. In the heat of furnaces it is not volatilized; but gold wire is dispersed in vapor by the oxyhydrogen blowpipe, by the heat of the sun's rays concentrated by a powerful convex lens, or by the electric battery. As the current traverses it, the vapors pro-

duced may be collected upon a sheet of paper placed beneath the wire; the paper is stained a purplish brown by the deposit of finely divided gold, and a sheet of silver may be thus gilded. When gold is fused in large quantity and allowed to cool slowly, cubical crystals are sometimes observed to form, and crystals of native gold have been found in the form of the regular octahedron. Gold is not acted upon by alkalies or simple acids, except selenic, nor by the oxygen of the air even when long exposed in a fused state. Neither does sulphur affect it; but it is dissolved by bromine and chlorine, or by any combination of acids or other substances in which free chlorine is present. This element, as it is generated in mixtures, is a powerful solvent of gold; and to it is due this property of the compound called *aqua regia*, formed of 4 parts of hydrochloric and 1 part of nitric acid. Gold forms alloys with most of the metals. Silver or copper increases its hardness and renders it better adapted for wear when used for coins, jewelry, or plate. Such compounds are also more fusible than pure gold. The solder for gold trinkets is 1 part of copper to 5 of gold, or to 4 of gold and 1 of silver. With mercury gold unites to form an amalgam. Mercurial fumes even, coming in contact with gold, instantly combine with and whiten it. The mercury may be driven off by heat. (See AMALGAM.) Gold is obtained from its solutions in various forms. The precipitate by sulphate of iron is a dull brown powder, which by pressure acquires the metallic lustre and color. The precipitate by oxalic acid is yellower and more metallic in appearance. The metallic gold which is left on evaporating a solution of its compound with chlorine and heating the residue is of a spongy character and dull hue; by annealing it becomes more dense and yellow, and by percussion is readily welded together. (For modes of preparing sponge gold and its uses, see DENTISTRY.)—Gold is very widely distributed in nature, and late researches have shown that it is present in appreciable quantities in the waters of the ocean, where it is associated with silver. According to Sonstadt, a ton of sea water yields by a simple chemical process a grain of gold; so that the quantity of the precious metal thus held in solution must be vastly greater than all the gold ever yet extracted from the earth. Gold is very generally diffused throughout the solid rocks, though only here and there accumulated in sufficient quantities to be economically available. The workable deposits of this metal are in stratified rocks of different formations, from the oldest crystallines to the postpliocene sands and gravels, and also in veins traversing rocks of various geological periods. The most common vein-stone of gold is quartz, but it is also found in bitter spar and disseminated in metallic sulphides, such as iron pyrites, which very often contains sufficient quantities of the metal to be extracted with profit. In this as well as in the

quartzose gangues the gold is sometimes in large grains or crystalline threads or masses, and sometimes disseminated in particles invisible to the eye. The opinion is entertained by many that in pyrites and in other sulphuretted ores the gold is sometimes chemically combined with the other metals and with sulphur. It has been found that the lead of commerce, from whatever source derived, is seldom or never without a trace of gold. Gold is not, as has been erroneously supposed, confined to rocks of any one geological period. The gold of Colorado is found in veins with metallic sulphurets traversing crystalline rocks of eozoic age, and the same is the case in Ontario; while the gold-bearing strata of the Appalachians are in large part if not wholly of pre-paleozoic age, as are those of the Alps and the Ural mountains. In Nova Scotia, on the contrary, the gold-bearing rocks are slates and sandstones, supposed to be of lower Cambrian age; and the auriferous strata of Wales as well as those of Australia are of that period. The gold-bearing veins extensively worked in Pennsylvania traverse sandstones of eocene or early tertiary age, and the gold-bearing quartz of California is said to be found in strata of the Jurassic formation. It is probable, however, that a part of the auriferous rocks of that country will be found to be eozoic, while on the other hand it appears that the silicious deposits now forming from the thermal waters in Nevada contain not only metallic sulphurets but small portions of gold; so that the processes which in former times gave rise to gold-bearing veins in that region are still in operation.—By the disintegration and crumbling away of the rocks which contain the auriferous veins, the contents of these are swept down to lower levels, and the gold by its density always seeks the lowest places among the moving materials. Thus are produced the auriferous gravel deposits in alluvial formations, the golden sands of the rivers; and so have they been gathering for long ages past and forming deposits, some of which are now seen in situations apparently out of reach of such agencies. In these deposits, when stripped of the clay and sands which cover the lower and richer layers, there are found in the irregular-shaped cavities of the surface of the rock, in pockets and in piles against the projecting strata, the accumulated riches of ancient veins, it may be, of vast extent. By washing away the intermixed earthy and stony matters, the metal is obtained in dust, flattened scales, small lumps, and nuggets of all sizes and shapes, the larger pieces rounded by attrition, or ragged from the irregular forms they held in their original hard quartz matrix. Their size is commonly greater than that of gold found in the veins near by; a fact first explained by the late Oscar Lieber of South Carolina to be due to the solution of gold and its subsequent aggregation. Later observations of Genth and Selwyn go to confirm this view. In these deposits the largest lumps

of gold ever met with were discovered, as that of Cabarrus co., N. C., of 28 lbs. avoirdupois, or 37 lbs. troy, found in 1810; the mass weighing 96 lbs. troy in Zlatoust, a district of the southern Ural, in 1842, and now in the imperial school of mines at St. Petersburg; a mass from Victoria in Australia, which was exhibited in London, and weighed 146 lbs. 3 dwts. troy, of which 6 oz. only were estimated as matrix; and the still larger mass found at Ballarat in that region, and weighing 2,217 oz. 16 dwts., or about 185 lbs. troy. According to Phillips, the largest piece of gold ever found was probably the great Australian nugget, known as the "Sarah Sands," which weighed 233 lbs. 4 oz. troy. Though in a metallic state, gold is never obtained pure; silver is always alloyed with it, but in no definite proportions. The purest specimen is probably one from the Ural, near Yekaterinburg, analyzed by Rose, which gave, in 100 parts, gold 98.96, silver 0.16, copper 0.35; its specific gravity was 19.099. The product of California is much of it very near the richness of gold of the American and French gold coins, which is 900 parts in 1,000. Its average, however, is stated to be  $\frac{87.5}{1000}$  to  $\frac{88.5}{1000}$ , and that of Australia  $\frac{86.0}{1000}$  to  $\frac{86.6}{1000}$ . A specimen of California gold, containing gold 90.70, silver 8.80, and iron 0.38, was of specific gravity only 14.6, and by fusing this was increased to 17.48. Gold from the Chaudière, Canada, of specific gravity 17.60, analyzed by T. Sterry Hunt, gave gold 87.77, silver 12.23; another specimen in fine scales, of specific gravity 16.57, produced gold 89.24, silver 10.76. Copper, palladium, and rhodium are also met with as alloys of gold. In Transylvania veins are worked producing an alloy of tellurium, gold, silver, and antimony; the tellurium commonly constitutes from 55 to 60 per cent., and the gold from 25 to 30 per cent. The same compound has been recognized at Gold Hill, N. C. Gold occurs in a few other combinations also with tellurium.—In the oldest records of the human race mention is made of gold, and like silver it was enumerated as an element of riches. Throughout the Old Testament there are frequent allusions to gold and to fine gold. It was beaten into thin plates, cut into wires, and even woven with threads of linen for the sacerdotal robe of Aaron. It was fashioned into breastplates with chains at the ends of wreathen work of pure gold; and it was used as the setting of precious stones. By other nations it was made into gods and idols, some of gigantic size. Aaron prepared a golden calf for the children of Israel, which Moses burned with fire and reduced to powder; an operation that might have been effected by first melting and beating it out into plates. In building the temple of Jerusalem the quantities of gold lavishly employed by Solomon for its furniture and decorations implied that it was largely collected, and that the ancients had access to mines of great extent and richness. Atahualpa, the

captured inca of Peru, agreed to bring together for his ransom, in the space of two months, articles of gold which should fill a room 22 ft. long and 17 broad to the height of 9 ft. When this was done and the gold melted, it was found to amount to 1,326,539 *pesos de oro*. The commercial value of the *peso*, according to Prescott, was equivalent to \$11 67, making the sum total \$15,480,710. The source whence the Phœnicians and Israelites derived their immense supplies of gold was the land of Ophir, a region still of uncertain locality. Once in three years the fleet of Solomon completed a voyage to it and back. Its other products besides gold brought back to Palestine (1 Kings x. 11 and 22), as ivory, spices, precious stones, ebony, peacocks, apes, and the almgug or sandal wood, indicate that it was in the tropics. It is generally presumed to have been either the East Indies or that part of the S. E. coast of Africa called Sofala by the Arabs. The auriferous character of the desert steppes of Gobi was known in the time of Herodotus to the inhabitants about the sources of the Indus; and to this day are to be seen along the southern Ural the works of ancient mining operations, supposed to be those of the nomadic Scythians. Ethiopia and Nubia also were largely productive of gold; and the ancient mines discovered by Belzoni in the Zabarah mountains are supposed to have furnished to the Pharaohs of Egypt their abundant supplies. Thus many auriferous regions appear to have been known at different times, as productive as those of the present period. While the gold of the deposits continued abundant they were vigorously wrought, and each district furnished in its turn the principal share of the production of the world. In the time of the Romans the precious metals were not so abundant, though rich deposits were worked along the foot of the Pyrenees, and in some of the provinces bordering the Alps. Strabo (B. iv. ch. 6, sec. 12) refers to the statement of Polybius that in his time the gold mines near Apulia were so productive that the value of gold was reduced one third in Rome. Spain, too, had its deposits worked in ancient times along the Tagus; and the Athenians gathered their supplies of the metals from Thessaly and the island of Thasos. In the middle ages the art of working gold appears to have been little practised. The richness of the known mines was comparatively exhausted, and previous to the opening of the new fields following the discovery of America, the attention of metallurgists was directed to vain attempts to transmute the baser into the precious metals. It was estimated that at the time of the discovery of America the gold and silver in the old world, exclusive of the more or less unknown regions of the East, was reduced to about £34,000,000, and that the supply no more than met the loss by wear. The enormous importation of gold and silver from the new world soon made up the deficiencies of the old mining regions, and, reducing the value

of the metals in comparison with other products, caused mines which had before been successfully worked to be abandoned as unprofitable. From 1492 to 1500 the annual amount of gold brought into Europe from America is rated by Humboldt at £52,000; till 1519 gold only was obtained. The same proportion may safely be extended to the year 1521, when Mexico was conquered, and the precious metals, but more especially silver, were obtained in vastly larger quantities. The mines of Potosi, discovered in 1545, gave a still greater preponderance to the production of silver, and no data are afforded for afterward distinguishing the relative proportions of the two metals. But in the first 300 years succeeding the discovery, the receipts of American gold were estimated at  $3\frac{1}{2}$  times the product of the mines of the old continent, and those of silver at 12 times the product of this metal. In the time of Queen Elizabeth gold was obtained at Leadhills in the south of Scotland; and toward the close of the last century, in the county of Wicklow in Ireland, about \$50,000 worth of gold was collected in two months. These deposits soon, however, proved unprofitable. The metal was in ancient times collected in Cornwall, and is known to exist in Devonshire. The largest portion of British gold has been the product of Wales, the principal gold-bearing district of which is confined to an area of about 25 sq. m. in North Wales. The mines are still worked, but there has been a great decrease in the production. Upon various rivers of Europe, as the Rhine, the Rhône, the Danube, the Reuss, and the Aar of Switzerland, the sands were known to be auriferous in places, but too poor to pay the expenses of working. In Hungary veins containing gold disseminated in ores of sulphuret of silver are worked in a partially decomposed feldspar of the trachytic formation, and also in syenite and porphyritic greenstone; and gold is also extracted from auriferous pyrites of trap rocks of the most recent formation. The mines of Nagy-Ág and Zalutna in S. W. Transylvania produce the alloy of tellurium and gold before referred to. Besides gold, the Hungarian mines, worked by the Austrian government, produce copper, silver, mercury, antimony, lead, iron, and cobalt. In the Austrian provinces of Salzburg and Tyrol, at Bockstein and at Zell, gold is extracted from poorer ores than are elsewhere ever found profitable to work. The quartz gangue of the veins and the argillaceous slates of the walls contain auriferous pyrites, argentiferous mispickel, gray argentiferous copper, and sulphuret of silver. From these the gold is profitably extracted when it amounts to only from 6 to 15 parts in 1,000,000. At Zell it has been stated that the annual product of 50,000 quintals of ore has been only 35 marks of gold, or 4 parts in 1,000,000. The silver, though obtained in six or seven times the quantity of the gold, is still less than half its value. The total production of the Austrian mines for several years past

has averaged from 5,500 to 5,800 oz. per annum. In Italy various localities were known to the ancients as producing gold. At present the only mines of consequence are in Piedmont, in the valleys of Anzasca, Toppa, and Antrona, and to a less extent in those of Alagna, Sesia, and Novara. In Lombardy the chief mines are at Peschiera and Minerva di Sotto. The ore is an auriferous pyrites containing about 12 dwts. of gold per ton. The total yield of all the mines does not exceed \$100,000 per annum. In France a small amount of gold is produced, chiefly from auriferous galena; and there are deposits in Savoy. Gold mines have been worked in Spain from very remote periods, but the present annual production does not exceed about \$10,000. The mines of the Asiatic slopes of the Ural extend along the secondary ridges of the chain in a N. and S. direction more than 400 m. The crystalline rocks here contain veins, one of which is successfully worked at Berezov, near Yekaterinburg, by shafts and levels. The gangue is pyritiferous quartz with oxide of iron resulting from its decomposition, and the rock is a partially decayed granite, the quartz remaining in angular grains; the adjoining formations are talcose and chloritic slates. All the other workings of Russia are alluvial mines. These are not only in the Ural district, where they have been worked for more than a century, but during the reign of Nicholas a region of southern and eastern Siberia, estimated to be as large as all of France, was found to be more rich in gold than that of the Ural. From the great E. and W. chain of the Altai mountains, which lie between Siberia and Mongolia, low ridges are directed toward the north into the governments of Tomsk and Yeniseisk, and these ridges of crystalline rocks are the repositories of the precious metals. In 1843 this region produced the value of about \$11,000,000, while the product of the Ural districts for the same year was only about \$2,500,000. Until the discovery of the mines of California it made Russia the greatest gold-producing country of the world. The average production of the Russian mines amounts to about \$15,000,000 annually; and their total production from their discovery about 1745 to 1874 may be stated in round numbers at \$600,000,000. The product in 1865 was given by Phillips at 69,500 lbs. troy.—Little is known of the other gold regions of the continent of Asia. The metal is possessed, and its deposits are no doubt worked to considerable extent, by all the principal nations; but except from the islands of the Indian archipelago little of it falls into the general circulation of the world. The river Pactolus of Asia Minor is supposed to have furnished from its golden sands the foundation of the wealth of Cræsus. According to Pumpelly, who made geological researches in China, Mongolia, and Japan during 1862-'5, gold exists in numerous localities in no fewer than 14 of the 19 provinces of China. The richest regions appear

to be in the province of Szechuen and along the branches of the Kuenlun mountain range, which, extending in a general E. and W. direction, penetrate far into central China, between Szechuen and the Wei river. There are also numerous washings at the base of the watershed between Kweichow and Hunan, and through the centre of Shantung from S. W. to N. E. In these localities placer gold is found, and some of them are mentioned as furnishing nuggets; but little is known of the production of these washings. It is said that extensive sources of gold have long been known in China, but that the working of the mines has been discontinued by the government in accordance with some of their financial theories. The gold-bearing formations of eastern Siberia are believed to extend into Chinese Tartary, and to connect with those of central and southern China. For several centuries Japan has ranked high for its production of gold, which constituted a chief article of the commerce carried on by the Portuguese and Dutch traders. According to a Japanese authority, the value of the gold exported from Nagasaki from 1611 to 1706 amounted to \$68,000,000, and of silver to \$157,000,000; while Hildreth states that the value of the precious metals exported from Japan during the two centuries beginning with 1540 could not have been less than \$200,000,000. But little is known concerning the present production of gold in the empire, or the localities where it exists. The gold regions on the island of Yesso were surveyed in 1862 by Blake and Pumpelly, while in the service of the tycoon's government. According to Blake, the gold region extends along the Kunui and Pusibets rivers and in the range of mountains dividing Volcano bay from the west coast. Deposits are also supposed to exist in the northern and interior portions of the island. No veins have yet been found, the gold being obtained from washings. It is in fine scales, and occurs in the gravel along the streams; it is also found in high terrace deposits on the hillsides. The annual product of the island does not probably exceed \$25,000. There are also extensive mines upon a large vein of mixed silver and gold ore on the island of Sado, off the N. W. coast, which is supposed to have furnished a large amount, but the facts regarding it are jealously guarded by the Japanese. Gold is largely used in Japan for gilding, for inlaying and overlaying metals, and for alloys with copper and silver of various colors and degrees of fineness. Gold has long been found in abundance in Borneo; according to Kloos, the metal occurs in varying quantities throughout the entire island. Placer gold is found on the river Kapola, associated with iron ores, sulphuret of antimony, and diamonds. The production of gold has also been reported in India, Thibet, Ceylon, Sumatra, Celebes, and the Philippine islands.—Africa is believed to have been the source of a large proportion of

the gold possessed by the ancients, and is reported by modern travellers to be still rich in it. The unmanufactured gold obtained from that country is in the form of dust, evidently obtained from alluvial washings. Russegger, who travelled through Nubia in 1838, reported the mountain chain extending across the interior of Africa from E. N. E. to W. S. W., and the streams flowing from it, to be auriferous. In Sennaar and southern Abyssinia gold occurs in placer deposits and in quartz veins traversing granite, gneiss, and chloritic slates. The greatest portion of the gold brought to the coast is from the fields of Bambook, south of the Senegal, the most important mines in Africa. There is a gold district in Kordofan on the upper Nile, between Darfoor and Abyssinia, and it is obtained in small quantities opposite Madagascar. A few years ago the annual production of Africa was estimated by Birkmyre at 4,000 lbs., valued at about \$900,000. In 1866 the existence of extensive gold fields in south Africa, between lat. 17° and 21° 30' S., was discovered by Hartley, an elephant hunter, and a German scientific traveller named Mauch. The gold fields occupy the interior region between the Zambesi, W. of Tete, and the middle course of the Limpopo river. The distance to them from the Portuguese settlement of Sofala is about 350 m. The region containing the gold is an elevated table land about 7,000 ft. above the sea; it is chiefly occupied by the Matabele section of the Caffres, a warlike tribe. The travellers above named found beds of glistening white quartz rock extending over this table land, which were found upon examination to contain gold. Particles of gold were also found along the sandy margins of rivulets. It is supposed by some that these mines were known to the Portuguese as early as the 17th century, and by others that here was the Ophir of Solomon. Although the discovery of the south African gold fields attracted considerable attention, the production hitherto seems to have been unimportant.—The first known discovery of gold in Australia was made by Count Strzelecki in 1839, and by him communicated to Sir George Gipps, then governor of the colony of New South Wales. In deference to the wishes of the latter, who was of opinion that a widely spread knowledge of the existence of gold would prevent the maintenance of discipline among the 45,000 convicts there collected, the discovery was not proclaimed to the world. It was rediscovered in 1841 by the Rev. W. B. Clarke, a geologist, upon whom also silence seems to have been enjoined by Governor Gipps. Without knowledge of these discoveries, it is said, Sir Roderick Murchison in 1844 publicly asserted the high probability of the existence of gold in Australia. It is also said that gold was found at Clunes, Victoria, in 1850. The discovery, however, which led to the extensive working of the mines was made in 1851 by Mr. E. H. Hargreaves, who had just returned from Cali-

fornia, and at once began prospecting near Bathurst on the Macquarie river, New South Wales, where gold was found in considerable quantities. The announcement of this fact caused much excitement and a sudden immigration of great magnitude to this region. (See EMIGRATION). The government at once laid claim to the land and began to grant licenses to dig for gold. The gold region was soon traced along the range of hills N. and S., and new discoveries were made of deposits surpassing all the rest in richness in the colony of Victoria, near the southern coast, 70 m. N. W. of Melbourne. In October there were 7,000 persons engaged in the new diggings at Ballarat near Mt. Buninyong, occupying less than a square mile in extent. The next month many of these were drawn off to the still richer deposits about Mt. Alexander in the same region, where it was estimated that 10,000 persons were then employed. In December 63,300 oz. were transported to Melbourne from this locality, which was then valued at £3 19s. 6d. per oz. The whole amount conveyed from the two localities from Sept. 30 to Dec. 31 was 124,835 oz.; the whole product of the colony was 345,146 oz. The immigration the next year of 104,000 more than doubled the population of Victoria; still richer diggings were discovered at Bendigo, and the total product of the colony for the year 1852 was estimated at 4,263,042 oz. The estimates made in London of the whole amount of gold exported from Victoria and New South Wales up to the close of 1852 gave for the former a total value of £16,000,000, and for the latter £3,500,000; or for 15 months nearly four times what the annual production of the world was supposed to be five years previously. The richest and most extensive gold fields of Australia are in the colony of Victoria, where the area of the mining region is about 725 sq. m. This is divided into the mining districts of Ballarat, Beechworth, Sandhurst, Maryborough, Castlemaine, and Ararat. In Australia, as in California, gold is directly obtained from three distinct sources, viz.: shallow placers, deep diggings, and quartz veins. The estimated number of quartz veins in Victoria is about 2,000. According to Selwyn, "these veins, traversing lower palæozoic strata and associated with granitic and igneous rocks, are, so far as at present known, the primary source of the whole of the gold raised in Victoria. The thickest and most persistent veins, or lines of reef, are found on the lower or older portions of the series; but the average yield of gold per ton of stone has, I believe, been greater from the thinner veins of the upper beds." The thickness of these veins, which are described as "dikes or reefs," varies from that of a thread to 130 ft. They have a general meridional direction, and are inclined either east or west at angles varying from horizontal to vertical. Frequently they occur in the planes of cleavage, occasionally between those of the strata, and they often

intersect both. These veins have been worked to a depth exceeding 600 ft., and it has been found that the yield does not decrease with increase of depth. Mr. Selwyn has reached the conclusion that at least two distinct sets of quartz veins exist in Australia, one of which is entirely barren, and that they have been formed at two different and remote periods, the barren being the older one. This view is corroborated by the fact, well known to experienced quartz miners in Australia, that in many districts barren and rich quartz ledges are found in close proximity. As this same phenomenon has been noticed in California and the Appalachian gold field, it suggests, according to Blake, the probable existence of quartz lodes of two or more distinct periods in America as in Australia. The greater portion of the gold obtained in Australia is from gravel deposits or placers similar to those in California. They occur in beds of streams, along the banks, and in ancient channels running transversely to the existing drainage of the country. Rich deposits are found under heavy accumulations of stratified tuffs and lavas overlaid with table mountains of basalt. The thickness of the placer deposits varies greatly in different places, ranging from 100 to 400 ft. The ratio of gold obtained from quartz mines to that of placers is indicated by the production of the two kinds in Victoria in 1866, viz., 521,017 oz. of quartz and 958,177 oz. of placer gold. The most productive gold fields of Victoria have been those of Ballarat and Bendigo. The general description of the gold fields of Victoria will apply to those of New South Wales. The alluvial deposits, however, are not so extensive as in Victoria, and the production of the colony has been less. South Australia and Queensland are also gold-producing, but the amount obtained is small. The Australian gold has a higher color and is finer than that from California. Its fineness ranges from 20 to 23.5 carats, the Ballarat gold being of the highest standard. The Ballarat nugget mentioned above, found in 1858, and weighing 2,217 oz. 16 dwts., was exhibited at the Paris exposition of 1867, and valued at nearly £10,000. Gold was first discovered in New Zealand in 1842; further discoveries were made there in 1851, and in 1856 mining operations on an extensive scale were begun. The rock formations and alluvial deposits, which are deep and extensive, are similar to those in Australia.—In the United States there are two extensive auriferous regions or gold belts, one on the Atlantic slope, known as the Appalachian gold field, and the other on the Pacific coast, embracing California and the neighboring states and territories. The Appalachian gold field extends southwesterly from Virginia through North Carolina, South Carolina, and Georgia, and also includes portions of Alabama and Tennessee. The width of the gold range varies greatly; in some places it exceeds 75 m. The metal does not exist in a continuous belt

extending through this region; but there are numerous auriferous tracts, occurring at intervals and generally parallel with each other, though often many miles distant. In North Carolina, from which the greatest amounts of gold have been obtained, there are two principal belts extending across the state in a S. W. and N. E. direction; one through Mecklenburg, Cabarrus, Rowan, Davidson, Guilford, and Caswell counties, and the other through Rutherford, McDowell, and Burke counties. The latter is the more westerly of the two, being from 10 to 20 m. distant from the base of the Blue Ridge; it is also more elevated, while the placer deposits are richer and more extensive than in the E. belt. In Georgia also the range appears to be divided into two belts, which are separated by unproductive rocks. Quartz veins closely resembling those of California are found in these regions. The gold is either free in coarse grains, or in fine particles disseminated in sulphuret of iron or copper. The gold veins of Virginia extend through Fauquier, Culpeper, Louisa, Fluvanna, Buckingham, and a few other adjoining counties. The production at times has been very large, but the veins have been extremely fluctuating in their yield; and though some of these still continue to be worked, their history on the whole is by no means favorable. Though gold has been found in Maryland, Pennsylvania, and Vermont, on the range of the Appalachian chain, it has proved insufficient to justify mining explorations, except over a limited area in Vermont during the year 1859. The veins of the southern gold region are found in various rocks of a granitic character, and in the hornblende rock called diorite, all of which are often in a decomposed condition to the depth of 200 ft. or more. They are also met with in a variety of slates, as talcose, micaceous, chloritic, and hornblende. In North Carolina a belt of such crystalline slates several miles wide is traced through several counties on the E. side of another belt of granite and W. of one of hornblende rock, in all of which the veins are found. In South Carolina the geognostical relations of the gold are very similar. Steatitic strata are met with near the mines, and dikes of intrusive rocks are often found cutting the veins and sometimes disturbing their regularity. The course of the veins is by no means uniform; they run in various directions, and are often tortuous as well as displaced by faults. Their most common general bearing is N. E. and S. W., with a dip toward the N. W. Veins in which the quartz gangue is highly crystalline commonly abound in iron pyrites; as they are explored, pyritous copper is generally met with at some depth. In most instances the gold diminishes with the increase of copper, and the latter metal not proving abundant enough to pay expenses, the mines are at last abandoned. Gold is said to have been discovered in Cabarrus co. in 1799, but until the early part of the present century the gold region of the southern

states attracted no attention. Gold had been gathered to a small extent in various places along the ranges of hills on the E. side of the Appalachian chain, between the Potomac and the Coosa river of Alabama; but there was no regular market for its sale, and no account was kept of the quantities collected. These were altogether of placer gold. In 1825 a gold vein was discovered by Mr. Barringer in Montgomery co., N. C., and attention was directed to this source, which in some instances proved highly productive; but this branch of mining was afterward most successfully prosecuted in Virginia, the coarse gold disseminated through the white quartz being more conspicuous than in the North Carolina veins. In the more broken country of the Carolinas and Georgia also the deposits of the streams were more attractive. In 1824 native gold began to appear in the mint at Philadelphia, and the receipts increased rapidly, so that in five or six years it constituted the chief portion of the supplies of this metal. Up to 1827 North Carolina had been the only state producing gold in notable quantities, and the aggregate amount from 1804 is estimated at about \$110,000. The first mint deposits from South Carolina were \$3,500 in 1829, and from Virginia \$2,500 in the same year. The first deposits of Georgia gold were in 1830 to the amount of \$212,000. In 1837 the production had become so great that a branch mint was established by the government at Charlotte, N. C., and another at Dahlonega, Lumpkin co., Ga., both of which commenced operations the next year. They were suspended in 1861, but in 1869 that at Charlotte was reestablished as an assay office. When the discoveries of gold in California were announced, the placer deposits and many of the veins in the south were abandoned. The total amount of southern gold deposited at the mints and assay offices of the United States, from the opening of the mines to June 30, 1873, was \$1,631,612 from Virginia, \$9,983,585 from North Carolina, \$1,378,180 from South Carolina, \$7,267,784 from Georgia, \$79,018 from Tennessee, and \$211,827 from Alabama; total, \$20,052,006. Of the deposits in 1873, \$2,423 came from Virginia, \$120,332 from North Carolina, \$160 from South Carolina, \$35,437 from Georgia, and \$599 from Alabama.—The existence of gold in California had been known from the time of the expedition of Drake, 1577–9, being particularly noticed by Hakluyt in his account of the region. The occurrence of gold upon the placers was noticed in a work upon Upper California published in Spain in 1690, by Loyola Cavello, at that time a priest at the mission of San José, bay of San Francisco. Capt. Shelvocke in 1721 speaks favorably of the appearance of the soil for gold, and of the probable richness of the country in metals. The "Historico-Geographical Dictionary" of Antonio de Alcedo, 1786–9, positively affirms the abundance of gold, even in lumps of 5 to 8 lbs. The favorable appearance of the country for

gold, and of Oregon also, was noticed by Prof. J. D. Dana, and recorded in his geological report of the country. In Hunt's "Merchants' Magazine" for April, 1847, is a very decided statement by Mr. Sloat respecting the richness of the country in gold, made from his observations there the two preceding years; and he confidently predicts that its mineral developments will greatly exceed in richness and variety the most sanguine expectations. In these years the Mormons connected with the army were known to have gathered some gold upon the banks of the streams, and the Mexicans and Indians also. A party of three Americans, two of them Mormons, were on Feb. 9, 1848, at Sutter's mill on the American fork of the Sacramento, near the town of Coloma in El Dorado co., engaged in repairing the race, which had been damaged by the spring freshets, when the little daughter of the overseer, named Marshall, picked up in the race a lump of gold and showed it to her father as a pretty stone. The discovery did not immediately attract much attention; and the Mormons particularly sought to prevent the facts from being made public. The Rev. C. S. Lyman, in a letter to the "American Journal of Science," of March, 1848, says: "Gold has been found recently on the Sacramento near Sutter's fort. It occurs in small masses in the sands of a new mill race, and is said to promise well." The news spread rapidly, and caused an unparalleled tide of emigration to pour in from Mexico, South America, the Atlantic states, and even from Europe and China. (See CALIFORNIA.) In August of that year Governor Mason reported 4,000 men engaged in working gold, and a daily product of the value of \$30,000 to \$50,000. The earlier diggings were mostly deposits resting upon the upturned edges of argillaceous slates, the gold being found entangled in these under the sand and gravel, and also more or less mixed through the superficial layers. A large proportion was picked out by hand at many of the diggings, so abundant were the coarse pieces. Attention was early directed to the gold veins, and in 1851 regular quartz mining was commenced at Spring Hill in Amador co. In 1857 numerous mills, most complete and thorough in their construction, were in operation over a great part of the country; and mines were opened at greater depths than gold is often worked in other countries. A shaft of the Mount Hope mining company in Grass Valley was carried to the depth of 241 ft., reaching the vein at 350 ft. following its slope, and the richness of the veinstone at this depth gave full encouragement to the belief that these repositories were permanent and inexhaustible. Many other mines were worked from 150 to 200 ft. in depth. In California, though gold is found E. of the Sierra Nevada, among the mountains of the coast, and in various other localities, the great gold region is on the W. slope of the Sierra, and extends from about lat. 35° N. northerly

to Oregon, a distance of about 500 m. The average breadth of this gold belt is about 40 m. The principal mining operations have been confined to a central area extending N. and S. about 220 m., between the parallels of 37° and 40°, and embracing Mariposa, Tuolumne, Calaveras, Amador, El Dorado, Placer, Nevada, Sierra, Yuba, Butte, and Plumas counties. According to William P. Blake, gold-bearing veins on the W. slope of the Sierra Nevada occur in or are closely associated with clay states, sandstones, and conglomerates of the secondary period; also in hard and compact granite, in greenstone or dioritic rocks, and in dolomite and metamorphic limestones. In the Coast mountains they are found even in the partially metamorphosed stratified formations of the cretaceous period. The largest and most extensive veins exist in the region of the metamorphosed secondary rocks, varying in width from a few inches to 20 or 30 ft., and generally conforming to the dip and strike of the strata. "The most extensive vein of the state," says Mr. Blake, "and perhaps in the world, is known among the miners as the 'mother vein,' and extends, but with some considerable breaks and interruptions, from Mariposa northwestward for 80 or 100 m., following a zone or belt of Jurassic slates and sandstones, and closely associated with a stratum of dolomite or magnesian rock, often a magnesite, filled with reticulations of quartz veins and charged with pyrites." The chief production of California gold has been obtained from placers. The great placer region extends over the central counties from Mariposa to Butte. The deposits occur not only in the beds of the streams, but also upon the hillsides and tops, where ancient watercourses are supposed to have been. Sometimes they are found under enormous accumulations of sand, clay, gravel, and even of tufa and lava; the smoothly worn stones are thoroughly cemented together, and form a solid conglomerate or "cement;" the auriferous deposits consist of gravel and boulders, varying in size from a grain of wheat to masses weighing many tons. These hills on the W. slope of the Sierra Nevada cover a tract of country in places 50 to 60 m. in width, and rise sometimes to the height of 4,000 ft. They are traversed by numerous streams, whose sources are in the Sierra Nevada. Subject to sudden and extreme freshets from the melting of the snows and from the long continued rains of the wet season, these streams excavate and sweep down the loosely aggregated rocks, and wear deep cañons and gulches, which extend toward the valleys of the Sacramento and San Joaquin. Thus it was the same agency which impressed this peculiar feature upon the topography of the region, and spread the gold from the veins in the hills through the ravines and down into the valleys. Even upon the elevated plains quite to the west of the hills gold is collected in strata of sand and clayey deposits, which cover the surface to the depth of 15 to

30 ft. or more. The clay is often seen to be but partially decomposed slate, still retaining the structure of this rock, which was evidently the matrix of the gold.—The general gold formation of California is found in the neighboring states and territories, the entire territories of the United States west of the Rocky mountains being more or less productive. In many parts of this region valuable mines are already worked, and there is little doubt that some of them may in the future contribute more than California to the general gold production of the country. In Nevada gold has been obtained from the quartz and from placers, but the product of the state has been chiefly derived from the auriferous silver ores of the great Comstock vein, discovered in 1859, which yields about one third gold and two thirds silver. Gold has been obtained from Oregon since 1850, and the recent production has been roughly estimated at about \$2,000,000 annually. It was first discovered in Washington territory on the E. slope of the Cascade mountains in 1858. The gold region was traced along the upper Columbia and its tributaries, and in 1860 it was found on the W. slope of the Bitter Root mountains, now in Idaho. There are gold washings in almost all parts of Idaho; the gold contains more silver than that of California, and averages about .760. In Montana there are extensive placers and quartz veins, on the E. slopes of the Bitter Root mountains, and on both sides of the Rocky mountain chain, at the sources of the Missouri river. In Colorado gold occurs in lodes or fissure veins, in a belt about 50 m. wide, extending over the central portion of the territory N. and S. (See COLORADO.) Gold is also obtained from Utah and Arizona, and is known to exist in Dakota. The auriferous belt of Oregon, and of Idaho, Montana, and Washington territories, extends N. along the slopes of the Rocky mountain chain into British Columbia. The mining of gold in this latter country dates from 1858, though the existence of the metal had been announced in 1856. Gold has been found on the Fraser river from a point about 45 m. from its mouth to its source in the Rocky mountains, a distance of upward of 700 m. by the meanderings of the river. It is also found on many tributaries of the Fraser and on Vancouver island. The fields which have been most extensively worked are in the Caribou district, which lies in the N. bend of the Fraser. N. of this district placers have been discovered on Peace river, and still further N. on the Stickeen, which empties into the Pacific S. of Sitka, near lat. 55°. The metal has also been found above that point, but in small quantities. The greater part of the gold from British Columbia is obtained from shallow placers. The production is sent to San Francisco; it amounted in 1873 to \$1,250,035. (See BRITISH COLUMBIA.)—In the province of Ontario, Canada, gold has been found in small irregular deposits of considerable richness in Madoc. The gangue of the gold was in part a ferriferous bitter spar,

and in part a peculiar hydrocarbonaceous coaly matter, the two being associated in the same veins, and alike penetrated by crystalline gold of great purity. The adjacent township of Marmora has since been found to contain gold in quartz veins with mispickel. Though not rich, the ore is abundant, and the deposits there are now worked on a considerable scale. The rocks of this region are crystalline schists, probably of Huronian age; and rich gold-bearing veins have recently been discovered in rocks of the same period N. of Lake Superior, on Lake Shebandowan. For many years the gold-bearing alluvions of the Chaudière and the adjacent region in the province of Quebec have attracted attention, and have yielded more or less gold. It is distributed over a large area, but the official returns in 1869 show a production of only 1,050 oz. from the Chaudière valley, although small quantities are extracted in various other localities in the region. The source of the gold appears to be in part in the adjacent crystalline rocks of Huronian age, and in part in some argillites and sandstones which are perhaps of the lower Cambrian period, but may be more recent. In both of these formations, native gold accompanied with sulphurets occurs in quartz veins, which have not however as yet been systematically worked. In Nova Scotia the auriferous quartz occurs in uncrystalline slates and sandstones, for the most part in interbedded veins. The workings have been on a small scale and very irregular, but the quartz is often of great richness. The official returns from 1860 to 1872 show a yield of 215,871 oz., with a value of £863,484. The produce in 1867 was 27,314 oz., but in 1872 only 13,094 oz.—The gold-producing districts of South America are in Brazil, Chili, and all those countries which lie north of the latter on the line of the Andes. As in Europe and Asia, it is the N. and S. ranges of hills of micaceous and talcose slates, quartz rocks, and granites, which produce this metal. In some instances, as in Peru and Chili, it is obtained from veins commonly worked for other metals as well as gold; but almost universally it is a product of alluvial mines. The yield since the early working of the mines has greatly fallen off, and especially since the commencement of the present century; and South America, from having been the first of the gold-producing countries in the world, has now fallen among those of least importance in this respect. Still it is well known that there are districts of great richness yet comparatively unworked, and which are likely long to continue so from their extreme unhealthiness and the want of means of comfortable subsistence. Such is the country about the head waters of the Atrato, the Magdalena, and the Cauca. Similar causes, as well as the political condition of the countries of Central America, have prevented the development of their resources in this metal, which it is well known follows the Cordilleras northward. On the isthmus of Panama discoveries of images

of gold in the graves of the aborigines point to the existence of productive mines in Chiriqui, the localities of which are not now known. The gold is very generally alloyed with copper; some of it indeed is only 8-carat gold, while in other samples the proportion is 23 carats. The gold of Mexico has been rather a secondary product of its argentiferous veins; but in Oajaca are true gold veins in the micaceous slates and gneiss. The silver ores which contain the gold are often argentiferous galena, the lead being the prevailing metal. A small quantity of gold is annually obtained from Central America, and gold placers are known to exist in Cuba and Santo Domingo. Although gold has been found in many places in Brazil, the most productive mines have been worked in the province of Minas Geraes in the vicinity of Ouro Preto, and in the district of Turayassu, in the province of Maranhão. The large production of Brazilian gold in the 18th century was obtained almost exclusively from the alluvial washings of Minas Geraes; but these became exhausted, and the metal is now obtained from the veins or beds worked by English capital. The gold found in Brazil, instead of being enclosed in regular veins, is disseminated in metalliferous beds. The rock formations are supposed to belong to the palæozoic period.—The total production of gold in the world has never been determined with more than an approximate degree of accuracy. There are no statistics showing the exact annual yield of the different gold-producing countries, and the amount produced has been subject to computations by different authorities, whose results have presented no little variance. It is true that in each country an accurate record is kept of the amount coined, and of the exports and imports, but these results only indicate approximately the extent of the production. In 1830 it was estimated that for the preceding 19 years the average annual production of the precious metals had fallen off about \$31,000,000 from what it had been before that time, the estimated product being as follows:

COUNTRIES.	Before 1810.	After 1810.
Europe and Asia .....	\$4,000,000	\$5,000,000
Indian archipelago .....	2,980,000	2,980,000
Africa .....	1,000,000	1,000,000
America .....	47,000,000	15,000,000
Total .....	\$54,980,000	\$23,980,000

By the estimate of M. Chevalier, in his work on money, the total amount of gold and silver existing in various forms in 1848 appears to have been £1,727,000,000, or \$8,500,000,000, of which one third was supposed to be gold. The annual product of this metal from 1800 to 1850 had been £3,258,000. By other authorities the whole amount of gold coin and bullion in Europe in 1847 was estimated to be about £250,000,000, and in the world in 1850 £600,000,000. According to Phillips, the annual production at the beginning of the century was

about 53,940 lbs. troy, of which New Granada furnished 23 per cent., Brazil and southern Asia 18 per cent. each, Chili 13, Mexico 8, Austria 6, and Peru 4 per cent. In 1860 the production had increased to 585,370 lbs. troy, of which the chief countries contributed in the following ratio per cent.: Australia, 37; California and neighboring states and territories, 31·9; Russia, 11·3. In 1865 the yield amounted to 559,587 lbs. troy, of which 37·5 per cent. was the product of California and the neighboring states and territories, 27·9 of Australia, and 12·4 of Russia. The following approximate statement of the value of the gold produced in the principal gold-producing countries in 1867 is given by Blake in his "Production of the Precious Metals:"

COUNTRIES.	Production.	Ratio per cent.
California .....	\$25,000,000	
Nevada .....	6,000,000	
Oregon and Washington .....	8,000,000	
Idaho .....	5,000,000	
Montana .....	12,000,000	
Arizona .....	500,000	
New Mexico .....	800,000	
Colorado .....	2,000,000	
Utah, Appalachians, and other sources.	2,700,000	
Total United States .....	\$56,500,000	43·23
British Columbia .....	2,000,000	1·96
Canada and Nova Scotia .....	560,000	
Mexico .....	1,000,000	·76
Brazil .....	1,000,000	
Chili .....	500,000	4·05
Bolivia .....	300,000	
Peru .....	500,000	
Venezuela, Colombia, Central America, Cuba, and Santo Domingo .....	8,000,000	
Australia .....	31,550,000	24·14
New Zealand .....	6,000,000	4·59
Russia .....	15,500,000	11·87
Austria .....	1,175,000	1·74
Spain .....	8,000	
Italy .....	95,000	
France .....	80,000	
Great Britain .....	12,000	
Africa .....	900,000	
Borneo and East Indies .....	5,000,000	3·83
China, Japan, Central Asia, Roumania, and other unenumerated sources ..	5,000,000	3·83
Total .....	\$130,650,000	100·00

The production of Australia above given is thus distributed by Blake: Victoria, \$26,510,000; New South Wales, \$4,500,000; Queensland, \$400,000; South Australia, \$140,000. Since about 1850, by far the greater portion of all the gold obtained in the world has been the product of the Australian mines and those on the Pacific coast of the United States. The extent of the Australian production is indicated by the following table, from the official "Statistical Abstract of the several Colonial and other Possessions of the United Kingdom," giving the value of the exports of bullion and coin from New South Wales and Victoria, from the opening of the mines. It should be observed, however, that it does not represent the exact production of each colony. The coin was issued from the branch of the royal mint at Sydney, New South Wales. A branch mint was established at Melbourne, Victoria, in 1872.

The exports from New Zealand began in 1857, and to the beginning of 1872 had amounted to £24,492,149. They increased from £40,084 in 1857 to £2,897,412 in 1866, then gradually decreased till 1870, when they amounted to £2,163,910, but in 1871 increased again to £2,788,368. The accurate determination of the amount of gold produced in the United States since the discovery of this metal in California is not practicable. As J. Ross Browne, W. P. Blake, R. W. Raymond, and others have shown, neither the manifests of export, nor the mint receipts, nor the bullion shipments of the express companies, nor any direct combination of these data, will give the required amount. This is particularly the case with regard to earlier years. The following table, compiled by R. W. Raymond, United States commissioner of mining statistics, is offered as an approximate estimate, the result of careful study of numerous treatises and partial statistics, in the light of much personal observation of the principal producing districts. Down to 1862 it follows the table compiled by J. Arthur Phillips, and published in his "Gold and Silver." From 1862 to 1866 the production of California is calculated by deducting from the express receipts of uncoined treasure at San Francisco, from "the northern and southern mines," the receipts from Nevada, and adding 10 per cent. to the remainder, to cover amount shipped in private hands. From 1866 to 1872 inclusive the reports of the United States mining commissioner have been followed as a general authority; but as these do not separate the product of gold from that of silver, the division has been made by estimate, based on the known conditions and relations of the industry of different localities. The figures for 1873 are based on the express shipments, with arbitrary allowances for product otherwise transported. Under the head of "Other States and Territories" is included the product of gold

from Oregon, Washington, Idaho, Montana, Colorado, &c., and one third the product of the Comstock lode in Nevada, that being the average proportion of gold by value in the Comstock bullion. The values are given in United States gold coin.

ESTIMATE OF GOLD PRODUCT OF THE UNITED STATES SINCE 1847.

1873.....	17,000,000	19,000,000	36,000,000
Total.....	\$955,500,000	\$254,950,000	\$1,240,750,000

Other authorities have made the production of California in recent years somewhat larger, as will appear by reference to the article CALIFORNIA.—It is estimated that about three fourths of the gold produced is used for coinage, and about one fourth in the arts. Thus, estimating the entire product of the world in 1873 at \$100,000,000, it is supposed that the consumption in the arts, which has greatly increased in recent years, approximated \$25,000,000. There has also been a recent increasing demand for gold for coinage, attributed to the fact that several countries which formerly used gold and silver as the double or alternate standard of value, have reformed their monetary laws, and adopted the gold standard, that metal being less variable than silver. Among the countries which have recently made this change are the United States, Germany, Denmark, Sweden and Norway, and Japan. Great Britain adopted the gold standard in 1816. France, Belgium, Italy, Switzerland, and Greece still adhere to the double standard. The total gold coinage of the world from 1848 to 1872 has been stated in round numbers at £602,116,000. Of this amount France coined £259,801,000, the United States £185,579,000, England £123,608,000, and Australia £32,128,000. According to the latest report of the director of the mint, the entire gold coinage of the United States to June 30, 1873, amounted to \$816,905,878, in addition to \$285,358,663 manufactured into bars, making the total issue from the

mints and assay offices \$1,102,264,541. (See COINS.) Of this amount coinage to the value of \$35,249,337 and bars valued at \$20,495,616 were issued during the year ending June 30, 1873. The amount of gold of domestic production, exclusive of coins, deposited at the various mints and assay offices of the United States from their establishment to June 30, 1873, with the sources of production, has been as follows:

SOURCE.	VALUE.	SOURCE.	VALUE.
Virginia.....	\$1,631,612 73	Washington territory....	\$71,662 41
North Carolina.....	9,983,585 88	Idaho.....	18,839,785 84

		Total.....	\$341,529,129 23

The localities given in this table are merely those from which the mint deposits were declared or inferred to come; hence they do not represent correctly the actual origin of production. A considerable amount, for example, is attributed to Kansas, which really produces no gold. The gold coinage of Great Britain and Australia for 10 years has been as follows:

YEARS.	England.		Sydney, Australia.	
	£	s. d.	£	s. d.
1863.....	6,607,456	5 4	1,876,962	9 10

The exports of domestic gold from the United States during the year ending Dec. 31, 1873, amounted to \$55,178,229 in coin, and \$12,754,257 in bullion.—GOLD MINING. Gold occurs principally in metallic form, as threads, scales, spangles, films, grains, monometric crystals, nuggets, &c. Such native gold always contains from 1 to 40 per cent. silver, and often also small quantities of iron, copper, mercury, palladium, platinum, or iridium. Gold ores proper are rare; the undoubted species are tellurides. More commonly gold occurs associated with other minerals, chiefly (in decomposed ores) the oxides of iron, and (in solid ores) iron and copper pyrites, galena, blende, mispickel (all of which may be auriferous), bismuth, stibnite, magnetite, hematite, various spars, and quartz. It is believed by many that auriferous pyrites often contains its gold in chemical combination with antimony, arsenic, or sulphur; but this is probably not the case with all py-

rites, or with all the gold in any variety of pyrites. Gold is classified further as quartz gold (found in veins, &c.), and wash gold (found in placers, gravel and cement deposits, &c.). The methods of extraction are mechanical, chemical, or both, according to circumstances. Mechanical methods involve the agency of air or water. Air separation is the rude process of winnowing, occasionally practised in localities where water is wanting. The dry pulverized material is repeatedly thrown into the air, allowing the wind to carry off the lighter portions, the remainder being caught as it falls in a hide or blanket, or a shallow wooden basin called a *batea*. The process is concluded by blowing the last residuum with the mouth. Washing is the almost universal method of mechanical separation. In exploring for gold, the earth or pulverized rock suspected to contain it is washed on the blade of a shovel, or in an iron pan, wooden *batea*, or horn scoop. The operation is commonly called panning. It consists essentially in stirring and shaking under water the contents of the vessels employed in such a way as to suspend the finer earthy particles and allow them to escape over the edge, while the gold, with the larger stones or lumps of clay, remains behind. The stones are removed with the fingers, and the lumps of clay are rubbed between the hands and reduced to a slime, the process being skillfully continued until nothing is left except gold and heavy black sand, usually titaniferous iron, which accompanies native gold in most localities and cannot be separated by washing. When perfectly dry, a part of it can be removed by blowing and a part by the magnet. It is common to melt the finer dust with fluxes and collect it in buttons. Quicksilver may also be introduced in panning, to take up and secure the fine gold. The cradle, or rocker, is an apparatus somewhat resembling a child's cradle. The box is usually about 40 in. long and 20 wide, and from 15 in. to 2 ft. high at the upper end, upon which is set a hopper or riddle, a box 20 in. square and 6 in. deep, having a bottom of sheet iron perforated with half-inch holes. Under the riddle is placed an inclined apron of canvas, and across the bottom of the main box are nailed two bars or riffles, about three fourths of an inch high. In washing, the dirt is shovelled into the hopper, and the workman ladles water upon it with one hand, rocking the cradle with the other. The sheet-iron bottom retains the larger stones; the disintegrated earth, passing through the riddle, falls upon the apron, which carries it to the head of the cradle box, whence it flows along the bottom and escapes at the lower end, leaving behind the riffle bars the gold, black sand, and heavier particles of gravel, which are cleaned up two or three times a day. This apparatus is both slow and wasteful in operation; but it is cheap and portable, and requires little water, since the same water can be used in it over and over again. The long tom is a wood-

en trough, about 12 ft. long, 20 in. wide at its upper end, and 30 in. at the other. It terminates below with an inclined riddle of punched sheet iron, through which the material is carried by a stream of water entering at the other end, and falls upon a riffle box below. A fresh supply of dirt is continually shovelled in at the head of the trough. This arrangement works faster than the rocker, and is not so liable to become packed with sand; but the sluice, which has now generally superseded it, is capable of washing still greater quantities and with less loss of gold. This is generally a long inclined wooden trough, into which the dirt is shovelled, and through which a rapid stream of water continually flows. The ordinary sluice is a series of rough wooden boxes, each 12 ft. long, 16 by 20 in. wide, and 10 in. to a foot deep. The grade is commonly 10 to 18 in. on each box. False bottoms are employed to retain the gold and prevent the wearing out of the boxes. Sluices are sometimes paved with stones or wooden blocks, in the crevices of which the gold is caught and retained. Riffles are also inserted, and quicksilver is very generally employed to assist in catching the gold. The dirt or gravel containing gold is shovelled into the sluices at the head of the series. Mercury is usually poured, an hour or two after the commencement of sluicing, into the head of the apparatus, and smaller quantities are also introduced at various places along the boxes. When the gold is exceedingly fine, amalgamated copper plates are sometimes set in the sluices, and are considered as effective for saving fine gold as an equal surface of pure mercury, while they are both cheaper and more easily managed. Another arrangement for obtaining fine gold consists in allowing a current carrying suspended gold, sand, &c., to pass over tanned hides, laid with the hairs directed against the course of the stream, or over rough baize or blanket, such as is now manufactured for the purpose in California. The blankets are frequently removed and washed in tanks. Where skins are used, as in Brazil, they may be dried and beaten over a cloth, placed to receive the fallen particles. Sluice washing is generally carried on during the day only; but when water is abundant and cheap, the work may be continued throughout the whole twenty-four hours. The sluices are cleaned up once a week, or more seldom, according to the rate at which gold and amalgam accumulate. The amalgam and mercury taken from the sluice are panned, to separate them from sand, &c., and then strained through buckskin or canvas to remove the liquid quicksilver. The auriferous amalgam is removed from copper plates by first warming and then scraping them. This, together with the solid amalgam from the strainers, is retorted; the quicksilver passing over from the retort is condensed in water and thus recovered; while the gold is left in the form of a light yellow porous mass, called retort gold, and usually constitu-

ting 35 to 40 per cent. of the weight of amalgam retorted. The length of the sluices employed in this process is limited only by the cost of their construction and maintenance, and the control of the necessary grade. Ground sluices are natural gullies, answering the purpose of wooden sluices in localities where water is abundant for short periods only, and the construction of permanent sluices would not be judicious. In river mining, the current of a stream is turned aside, and sluices are erected in its bed for washing the dirt there accumulated. In beach mining, as carried on along the northern part of the California coast and the southern part of the Oregon coast, the sands on the seashore are explored, and certain portions of them, which are found to be sufficiently auriferous, are transported to some neighboring stream and washed. The origin of this gold is the natural concentration by tides and currents of a bluff of auriferous sand, which in stormy weather is undermined by the waves. The position of the deposits is frequently changed, and mining must therefore be carried on in a new place every day.—Hill diggings and bank diggings are names which explain themselves. Many deposits of auriferous clay and gravel have been subsequently overlaid by barren alluvium; and the ordinary operations of shovelling or blasting would be too expensive for the removal of such enormous masses of unprofitable material. Tunnels and drifts are frequently employed for the purpose of extracting the richer strata. They are particularly necessary in those deep placers in which the drift materials are united by silicious or calcareous matter, constituting a hard, solid cement. This material is usually mined by drifting, and, if too hard for sluicing, is subjected to a treatment similar to that employed for quartz gold. Water for sluicing operations is frequently brought from great distances through canals, ditches, or flumes, the proprietors of which sell the water to miners at so much the miners' inch, a miners' inch being in most localities the quantity flowing in a given time through an aperture one inch square under a head of six inches.—The celebrated hydraulic process, invented in Placer co., Cal., in 1852, consists in washing down the whole surface and underlying mass of auriferous deposits, preparatory to sluicing. This is effected by streams of water under great hydraulic pressure. The first apparatus of the kind had a head of 40 ft. From a barrel situated this distance above the mining claim the water was drawn through a hose 6 in. in diameter, made of common cowhide and ending in a four-foot tin tube, the nozzle of which was one inch in diameter. From this simple beginning has grown in 20 years one of the most remarkable mechanical industries of mining. Hundreds of miles of ditches, canals, and flumes are now employed in conducting water for these operations from the high streams of the Sierra; canvas and iron hose have replaced the original

cowhide; blasts of from 5 to 50 tons of powder at a time are fired, to prepare the ground for the action of water; nitro-glycerine and the diamond drill are used in running preparatory tunnels for drainage; chasms of 1,000 ft. in vertical depth are successfully crossed by huge iron pipes, to convey water to isolated points, thus obviating the ancient high, costly, and perishable flumes; and from ingeniously contrived and regulated nozzles streams as much as 6 in. in diameter are discharged under pressures sometimes exceeding 400 ft. of hydraulic head, with a velocity of 140 ft. and upward per second, delivering more than 1,600 lbs. of water in that unit of time. The water issuing from the nozzle seems to the touch as rigid as a bar of steel, and strikes the gravel bank in the same cylindrical, condensed shape, boring into it with immense power. The heavy bowlders are thrown about like pebbles; and the clay, earth, and gravel, disintegrated by the torrent, are swept along into the system of sluices. It has been estimated that, taking the miners' wages in California at \$4 per day, the cost of handling a cubic yard of gravel would be nearly as follows: in the pan, \$20; in the rocker, \$5; with the long tom, \$1; by hydraulic process and sluices, 5 cts. This method has rendered valuable many California placers that were esteemed worthless or exhausted; and its employment would doubtless revive the importance of abandoned gold fields in other parts of the world.—Quartz gold (that is, gold contained in veins, whether native in the quartzose or other gangue, or associated more or less intimately with metalliferous minerals) is extracted in most cases by first pulverizing the material, and then washing and amalgamating. Stamp mills, iron rollers, revolving plates, drums containing iron balls, Chilian mills, arrastras, and jaw crushers are among the machines employed in pulverizing rock. The arrastra consists of a circular pavement of stone, about 12 ft. in diameter, surrounded by a rough curb and forming a kind of tub about 2 ft. in depth. An upright shaft, working on a pivot in the centre of this circle, carries arms to which large stones or mullers are attached by chains or thongs. The arms, being revolved by horse or mule power, drag the mullers over the pavement, upon which the ore, previously broken into pieces of about the size of pigeons' eggs, is distributed. Water is added from time to time, until the quartz has become reduced to a finely divided state, and the contents of the arrastra assume the consistency of thick cream. Quicksilver is then sprinkled over the surface, and the grinding is continued until amalgamation is complete. An ordinary twelve-foot arrastra will grind and amalgamate 450 lbs. of quartz in about seven or eight hours. The amalgam is obtained by diluting and agitating the mixture, and allowing the turbid liquid to run off. The arrastra is slow in operation and wasteful of power, but an excellent amalgamator. Hence the

principle has been very generally adopted in amalgamating, while the preliminary pulverization is effected by other machinery. The Chilian mill consists of a stone or iron basin, around which one or two vertical wheels or runners, frequently of granite, are made to travel. It is generally considered less efficient for amalgamation and scarcely more so for crushing, while it is more expensive to construct than the arrastra. Jaw crushers, of which Blake's well known stone breaker is the type, are widely employed for the preliminary reduction of rock to a size suitable for rollers or stamp mills. Stamping is usually regarded as the most economical and efficient means of pulverizing the ore. The mills constructed for this purpose are run by steam or water power, with the exception of occasional rude contrivances in which single stamps have been operated by horse power, and of the experiment now making, it is believed for the first time, in the island of Arruba, where wind is to be employed as a motive power. The best stamp mills in the world are believed to be those of California and Nevada. These are made up of batteries containing three, four, five, or six stamps each; five is the usual number. Each battery works in a cast-iron box or mortar, in the bottom of which are laid blocks of hardened iron, called dies, to receive the shock of the falling stamps. The broken rock is fed in suitable quantities into the mortar, and crushed between the dies and the stamps. Each stamp consists of a stem, a collar, a stamp head, and a shoe. The stem was formerly made of ash or other hard straight-grained wood, about 6 in. square, to the lower end of which a square iron stamp head was fastened. At present, in California, stems of 3 or 3½ inch round iron, some 12 ft. in length, are universally employed. The collar is secured upon the upper part of the stem, and forms a projection 3 or 4 in. wide, under which the cam of the horizontal driving shaft catches and lifts, and at the same time turns, the stamp. The stem fits below into the stamp head, a cylinder of tough cast iron, furnished on its lower face with a hard iron shoe, which can be replaced when worn out. The stamps are dropped 6 to 12 in., at the rate of from 25 to 90 drops per minute. Water flows into the mortar with the ore; and the finely divided product is splashed by the stamps through screens of wire cloth or perforated sheet iron, set in the walls of the mortar. Loose quicksilver and amalgamated copper plates are sometimes used inside the mortar. The mixture of crushed ore and water is differently treated in different places for the extraction of gold. Sometimes it is run over amalgamated copper plates; sometimes it is first concentrated by means of blankets; sometimes it is introduced into pans, somewhat on the principle of the arrastra, or into various other ingenious forms of apparatus, for the purpose of amalgamation. In the most suc-

cessful establishments, the current conveying the sediments is led through a succession of apparatus, each machine, sluice, or other contrivance being intended to catch a portion of the gold carried past the preceding one. The refuse finally escaping is called tailings, and usually contains: native gold, so finely divided that it has been swept by the current through all the apparatus employed; minute particles of amalgam and "floured" quicksilver, carried off in the same way; coarser particles of gold adhering to fragments of rock; and, finally, gold associated mechanically or chemically with iron or copper pyrites, blende, galena, and mispickel. The tailings are usually run into reservoirs, allowed to settle, and then stored in heaps. Sometimes these heaps are again amalgamated, with or without a preceding concentration by washing. It has been found in many instances that some kinds of pyrites slowly decompose by exposure and thus set free fine gold. The metallic sulphurets are, however, in many cases, separated from other tailings by washing immediately after the first amalgamation of the ore, and various devices have been employed for the treatment of such concentrated pyrites, which is often the richest in gold of all the constituents of the vein stuff. Following the analogy of natural decomposition, it has been repeatedly attempted, by roasting the pyrites in reverberatory furnaces, to drive off the sulphur and oxidize the metallic bases, so as to obtain a product containing fine particles of free gold. The objection brought against this treatment, that the vapors of roasting carry off mechanically fine particles of gold, seems to be ill-founded. More serious objections are the cost of the roasting process, and the circumstance that the roasted product does not contain the gold in a condition suitable for amalgamation. It is supposed that the particles when thus artificially and rapidly reduced become coated with a film of oxide of iron, preventing the intimate contact with quicksilver upon which amalgamation depends. Very careful roasting in cylinders, with the addition of salt, is said to have obviated this difficulty; but the question of expense remains.—The present methods of treatment for pyritous gold ores are: 1, the extremely fine pulverization of the ore, liberating, as far as this is mechanically possible, the particles of gold; 2, the amalgamation of the pyritous residues in pans, with the addition of chemicals intended to facilitate decomposition; 3, chlorination; 4, smelting. The chlorination process was introduced by Prof. Plattner of Freiberg, Saxony, for the treatment of auriferous residues in Silesia. As improved by Deetken, it has been employed in this country for about 15 years. The principle involved is the transformation of metallic gold by means of chlorine gas into soluble chloride of gold (the *aurum potable* of the alchemists), which can be dissolved in cold water and precipitated in the metallic state by

sulphate of iron. This precipitate may then be filtered, dried, and melted with suitable fluxes, to obtain a regulus of malleable gold. It is necessary that all the gold, and if possible nothing else, shall be obtained in the final solution. If this is secured, the precipitation and melting are easy. To render the gold in the ore accessible in a metallic state to the chlorine gas, and at the same time to convert the base metals into oxides which will not unite with the chlorine, the raw ore is finely pulverized and (if sulphurets or arseniurets are present) roasted. The cost of this treatment, amounting in the Pacific states and territories to from \$12 to \$25 a ton, excludes its use for low grade ores; and hence it cannot supersede the stamp mill and amalgamation process, though it is acknowledged to be metallurgically the most complete method of gold extraction on a large scale. Ores containing iron, copper, gold, and silver may be roasted and deprived of their copper and iron by leaching with dilute sulphuric acid, of their silver by boiling with concentrated sulphuric acid, and of their gold by treating the auriferous residuum with aqua regia. If lead is present, the whole residuum after the removal of copper must be melted with lead and cupelled. This process is not now used in the United States, though it is recommended by high authority. Telluric ores are treated in Transylvania in a somewhat similar way. The smelting processes for the extraction of gold are the same as those for silver. Since the two minerals always occur in nature together, the final result of smelting is argentiferous gold or auriferous silver. The separation of the two metals is effected: 1, by dissolving the silver in nitric acid or boiling sulphuric acid, which leaves behind a brown powder of gold; 2, by treating the alloy with aqua regia, in which gold is dissolved as chloride, while the chloride of silver is but slightly soluble; or 3, by passing a current of chlorine gas through the alloy while in a melted state. For separation with nitric acid, the alloy should contain  $2\frac{1}{2}$  parts of silver to 1 part of gold. For the separation with sulphuric acid, the best results are obtained with alloys containing not much less than 3 or more than 4 parts of gold in 16 parts, the remainder being silver and copper. It is usually necessary in treating native gold to melt it with at least  $2\frac{1}{2}$  times its own weight of silver, and then to separate by the action of acids the silver thus added, and also that originally contained in the gold. It is said that the chlorine process effects a complete separation of the silver in one operation, at the time the gold is melted, and thus saves much time, material, machinery, and interest on capital. Nitric acid and sulphuric acid processes are used in the mints of the United States, and the chlorine process is employed in some of the British colonial mints.—Among the most recent authorities on this subject are: Phillips, "The Mining and Metallurgy of Gold and Silver"

(London, 1867); J. Ross Browne, "Mineral Resources of the Pacific Slope" (New York, 1868); Blake, "Production of the Precious Metals" (New York, 1869); R. W. Raymond, "Silver and Gold" (New York, 1873). See also Selwyn's "Notes on the Physical Geography, Geology, and Mineralogy of Victoria" (Melbourne, 1866), and the reports on the geology of California by J. D. Whitney.

**GOLD-BEATING**, the process of hammering gold into thin leaves. It is not known what were the methods in use by the Egyptians, Greeks, and Romans for obtaining the thin leaves they manufactured; but it is probable that they did not differ essentially from the simple processes now practised, which were brought to their present perfection by continued experience and the application of a moderate degree of skill. The earliest recorded notice of the mode of preparing gold leaf is that of the German monk Theophilus, in or before the 12th century, from which it appears that parchment was used as a covering to the gold during the hammering, and the leaves were prevented from sticking by the application of red ochre or chalk. When the substance called gold-beaters' skin (French, *baudruche*) was first used for the production of the finest qualities of gold leaf is not known. This material, essential to the manufacture, is derived from the cæcum of the ox, which, being well cleaned, is doubled together, the two mucous surfaces face to face, in which state they unite firmly. The membrane is then treated with solutions of alum, isinglass, white of eggs, &c., and sometimes with creosote, and, being beaten between folds of paper to expel the grease, is finally pressed and dried. The leaves thus obtained, each  $5\frac{1}{2}$  in. square, are made up into moulds, each composed of 850 leaves. The cæca of 500 oxen are required for a single mould.—Various qualities of gold are employed for gold leaf. The common coin answers a very good purpose, and different shades of color are obtained, according to the proportions of silver and copper in the alloy. Chemically pure gold makes leaves well adapted for gilding which is to be exposed to the weather, as they are less liable to tarnish or change color; these are remarkable for their property of adhering as they touch each other. Deep red colors are obtained by alloys of 12 to 16 grains of copper to the ounce of gold; silver, if added when too much copper is present, lessens the malleability of the alloy. Medium colors, as orange, lemon, &c., result from the alloy of 12 to 20 grains of silver and 6 to 8 of copper to the ounce; and pale colors from alloys of from 2 to not less than 20 pennyweights of silver to the ounce, without copper. The gold, being melted in a crucible with a little borax, is cast into ingots, commonly 3 or 4 in. long,  $\frac{3}{4}$  in. wide, and about  $\frac{1}{2}$  in. deep, and weighing about 1,000 grains each. The ingots are annealed in hot ashes to remove the grease derived from the moulds and increase the malleability of the

metal. The French then forge the metal upon an anvil with small hammers, reducing its thickness to one sixth of an inch, and at the same time exposing it to frequent annealings; but this is omitted by the English, who submit it at once to the lamination process, or rolling between two rollers of polished steel, which are adjusted so as to be brought successively nearer together. This operation, which formerly reduced the gold to a ribbon an inch wide and  $\frac{1}{5}$  of an inch thick, is by improved machinery now extended till the gold is reduced to a sheet a little more than  $\frac{1}{80}$  of an inch thick, an ounce making 10 ft. in length by  $1\frac{1}{2}$  in. in width. The gold, again annealed, is next cut up into inch squares, the weight of each being about 6 grains. About 150 of these pieces are piled alternately with leaves of fine calf-skin vellum or of a tough paper manufactured in France for this purpose, each piece being placed in the middle of one of the leaves, which are 4 in. square. A number of extra leaves are added to the top and bottom of the pile, which when completed is called a tool or kutch. This is then slipped into a parchment case, open at two ends, and this into a similar case, so as to enclose the pack on all four sides. The pack is now placed upon a block of marble, set for an anvil, with a ledge around three sides of it, and a leather apron for the fourth side, which is held up by the workman, who proceeds to beat the pack. He wields a 16-lb. hammer, shifting it from one hand to the other without interfering with the regularity of the stroke, also occasionally turning the pack with the same dexterity. The hammer has a slightly convex face, which adds to its efficiency in spreading the gold, and the working of it is made much easier by the elasticity of the pack causing it to rebound. The pack is from time to time bent back and forth to overcome the adhesion between the gold and the vellum or paper; it is also rolled between the hands for the same purpose; and it is occasionally opened to examine the condition of the leaves and properly arrange them. In about 20 minutes' beating the gold is spread to the size of the leaves, covering 16 square inches in place of one inch. The pieces are then taken out, and each is cut into four square pieces, the original 150 pieces being thus increased to 600. These are again packed, this time in gold-beaters' skin, again enclosed in parchment cases, and beaten with a smaller hammer, till they are extended to the size of the skins. This operation requires about two hours. More particular care is given now than before to folding the pack in order to loosen the leaves. When all the gold leaves have expanded to the full size, they are taken out and spread by the breath one by one upon a cushion, where each is cut into four squares by two sharp edges of cane fixed crosswise, and used by pressure downward. To this material the thin leaves do not adhere as they do to a steel blade. The squares are now 2,400 in number. These are once more

packed, making three parcels, and beaten as before for four hours. This part of the process requires the most skill and care from the workman. The skins are the finest, about 5 in. square; the leaves are brought at the end of the operation to 3 or  $3\frac{1}{2}$  in. square. In this condition an ounce of gold is made to cover 100 sq. ft. It begins to transmit the rays of light, and, if slightly alloyed, the green rays particularly, but, if highly alloyed with silver, the pale violet rays also. The beating may be continued, and the gold be reduced to the thinness of the specimens noticed in GILDING; but there is no advantage gained in passing the average of the commercial gold leaf, which is about  $\frac{1}{250,000}$ , or that of the French, which is probably less than  $\frac{1}{250,000}$  of an inch thick. The leaves are sorted after the final beating, each one being lifted by a delicate pair of whitewood pincers, and spread out by the breath upon a leather cushion. It is then trimmed down to about  $3\frac{1}{2}$  in. square by a square frame of sharp cane, and laid between the leaves of the book in which it is sold. Each book is made to contain 25 gold leaves, and these are prevented from adhering to the paper by an application to this of red ochre or red chalk.—Silver and copper are both beaten into leaves; but their value is not so great as to render it an object to reduce them to anything like the tenuity of gold leaf, if their malleability admitted of its being done.

**GOLDBERG**, a town of Prussian Silesia, on the Katzbach, 10 m. S. W. of Liegnitz; pop. in 1871, 6,716. It is quaintly built, and has a church dating from the beginning of the 13th century. Cloth and hosiery are manufactured, and there are dye works and distilleries of brandy. The gold mines from which it derived its name are not now worked. A battle was fought here, May 27, 1813, between the French under Macdonald and the Russian reserve under Wittgenstein, and a skirmish (Aug. 23) between the former and Blücher.

**GOLD COAST**, a part of the coast of Upper Guinea, W. Africa, lying, according to most geographers, between Cape Three Points and the river Volta; but the jurisdiction of the British Gold Coast colony, including the territories ceded by the Dutch in 1872, extends from the river Assinie, lon.  $3^{\circ} 18' W.$ , to the river Ewue, lon.  $1^{\circ} 10' E.$ ; area, 16,626 sq. m.; pop. in 1871, 408,070. The shore line, about 330 m. long, is skirted generally by low hills with dense woods in the background, but is flat and sandy at its extremities, with lagoons inland. There are no harbors, and the surf is so violent that vessels are obliged to lie from 2 to 5 m. off the beach. The chief rivers are the Assinie, Ancober, Tenda, Bossum Prah or Prah, and the Volta. The Gold Coast colony proper consists of only the fortified stations and the strip of coast dominated by them; but a protectorate is exercised by Great Britain over all the tribes lying between it and Ashantee. The limits of the protectorate are not clearly defined, but it is generally understood to extend inland about 80

m., the river Prah forming its N. boundary in the longitude of Elmina and Cape Coast Castle. The principal native people inhabiting this territory are the Fantees, but there are a number of smaller tribes, the Ahantas, Wassas, Denkiras, Akims, Assins, Aquapims, Crepees, and others, all under independent chiefs. Little is known of the interior, but the few who have penetrated it speak of its vast forests filled with tropical life, and of green plains traversed by sparkling streams, and its climate is said to be more healthy than that of the coast. There are no roads, the only means of communicating between the villages being by narrow paths, passable only in single file. Beasts of burden are unknown to the natives, who transport all merchandise and produce to and from the coast on their heads. The soil is very fertile, producing all the tropical grains and fruits. Traces of iron are found at several places on the coast, and there are rich gold mines in the interior. In the beginning of the 18th century the Dutch exported annually from Elmina about £250,000 worth of gold dust, but the hostility of the native tribes has now nearly destroyed the trade. The fortified posts of the Gold Coast colony are Axim, Dixcove, and Sekundi, in the Ahanta country, and Elmina, Cape Coast Castle, Anamboo, and Accra, in the country of the Fantees. The French trading station at Assinie has been abandoned since 1870. Axim, about 14 m. W. of Cape Three Points, is one of the healthiest places on the coast, owing probably to the pure water which runs from the neighboring hills in rivulets. All the tropical plants grow to perfection in its vicinity, and many European vegetables have been successfully introduced. It is the only place where rice is raised, and the influences so deadly to live stock at other points do not extend to it. In the country N. of it are rich gold mines, and gold dust, palm oil, and palm kernels were once exported in considerable quantities. The town is commanded by Fort St. Anthony, built in its centre on a precipitous rock 70 ft. high. Dixcove (called Unfuma by the natives), 11 m. E. of Cape Three Points, is defended by a fort, which the Dutch thoroughly repaired in 1867. The town is dirty and unhealthy, from the exhalations of neighboring swamps, which harbor numerous crocodiles. Between Axim and Dixcove are the ruins of the old forts Great Friedrichsburg, Brandenburg, and Dorothea, built originally by the Prussians. Bautri or Boutry, 3 m. E. of Dixcove, a former Dutch settlement which was defended by Fort Batenstein, is now abandoned. Sekundi, the next station, 20 m. from Dixcove, is situated on a point, with Fort Orange on a steep promontory at its end. The environs are fertile, and the country back of it is covered with dense woods. The former Dutch settlement of Chama is 8 m. further E., near the mouth of the Prah. It is commanded by Fort St. Sebastian, originally built by the Portuguese, and still in a fair state of repair, but abandoned on account of the unhealth-

fulness of the locality. The Dutch cultivated here cotton, flax, hemp, coffee, tobacco, and ground nuts, with much success. From Chama to Elmina is about 20 m. Between are the native towns of Kommenda (pop. 4,000), with the ruins of an old English fort; Kommanie (pop. 2,300), with the remains of the Dutch fort Vredenburg; and Ampeni (pop. 4,500). Elmina, called by the natives Oddena, the capital of the former Dutch colonies, had a population of 15,000 in 1867. (See *ELMINA*.) Cape Coast Castle, 8 m. E., the capital of the Gold Coast colony (pop. 10,000), derives its name from its fortress built on rocks near the seashore. Behind, on a gentle slope, is the European town, with picturesque houses surrounded by gardens of tropical fruits. Anamboo or Anamabu, 10 m. E. of Cape Coast Castle, and Accra or Akrah, nearly 70 m. further, are the two most easterly fortified settlements on the coast, but there are missionary stations at several intervening points. The slave trade is virtually abolished, but domestic slavery exists to a great extent throughout the protectorate. The principal exports are gold dust, palm oil and kernels, gum, ivory, and monkey skins; the imports are cotton and silk goods, guns, gunpowder, hardware, tobacco, and wines and spirits. The total tonnage of vessels entered and cleared, exclusive of coasting trade, in 1871, was 251,047. The total value of imports for 1871 was £250,672, of which £171,978 were from Great Britain; total value of exports in 1871, £295,208. The chief trade previous to 1872 was with the Ashantees.—Since 1850 the colony, previously under the jurisdiction of Sierra Leone, has had a government of its own, with a governor and executive and legislative councils. It has also judicial, military, ecclesiastical, and educational establishments. The gross amount of public revenue, raised in part by a tax of 3 per cent. on imports, was in 1871 £28,609; gross expenditure, 1871, £29,094. An attempt was made to impose a poll tax of a shilling a head on all the protected natives, which in 1852 produced £7,567; in 1861 it had fallen to £1,552, and since then it has not been levied. The Dutch did not levy any import duties.—The first European nation to establish themselves on the Gold Coast were the Portuguese, who began the fort at Elmina in 1481. In 1637 it was captured by the Dutch, and three years later all the Portuguese possessions on the coast were ceded to them. In 1662 the "Company of Royal Adventurers of England trading to Africa," and in 1672 the "Royal African Company of England," built rival forts and factories near the Dutch company's settlements, which resulted in constant disagreements and quarrels. In the war of 1781 the English captured all the Dutch forts except Elmina. On their restoration by the treaty of Versailles, the states general assumed the government of the colony, but the rivalry continued and frequently led to bloodshed between the negro

tribes of the two jurisdictions. Considering that this unsatisfactory state of affairs was due principally to the positions of the forts of the two nations, which alternated with each other, an agreement was made in 1867 that the boundary line between the colonies should be the Sweet river, a small stream between Elmina and Cape Coast Castle; that all the settlements E. of this point should belong to England, and all W. of it as far as the Assinie river to the Netherlands. In accordance with this treaty, the Dutch ceded Mori, Kormantin, Assam, Bereku, and Fort Crèveceur at Accra; the English, Apollonia, Dixcove, Sekundi, and Kommenda, and the protected territories of Wassa, Denkira, and Tufel. The Dutch forts were surrendered to the English without trouble, but the natives resisted the transfer of the English stations to the Dutch. Disturbances ensued, and on Jan. 31, 1867, the Dutch burned Kommenda as a punishment. In 1868 they burned Sekundi in retaliation, and in 1869 Dixcove. The natives became only the more incensed at these measures, and the Dutch government, despairing of peace, agreed, by a treaty ratified at the Hague Feb. 17, 1872, to transfer all its possessions to England, which was formally done the following April. The Danish settlements had previously been ceded to Great Britain (in 1850), so that the latter power now controlled the whole coast. The king of Ashantee, who had been accustomed to draw his supplies of arms and ammunition through the Dutch factories free of duty, objected to the transfer of the forts, which cut him off from access to the coast, and declared that the Dutch had no power to transfer Elmina, which he said belonged to him, the Dutch having paid him a tribute of £300 a year. In January, 1873, the Ashantees crossed the Prah and invaded the protectorate. The protected tribes offered but a feeble resistance, and in June both Cape Coast Castle and Elmina were threatened by a force estimated at 50,000 men. The native king of Elmina aided the Ashantees, and four out of the eight captains of the quarters into which the town is divided refused to take the oath of allegiance. On June 30 the quarter of the native king was bombarded by the fort and destroyed, and in the afternoon of the same day the Ashantees were defeated with a loss of 500 and their general, and withdrew to Efutu, 12 m. distant. In August Takorady was bombarded by the British fleet, Dixcove repelled an attack of the Ashantees, and Axim, where the natives rose against the garrison, was burned. In October Gen. Sir Garnet Wolseley was sent from England to Cape Coast Castle with both civil and military powers. Early in January, 1874, he set out for Koomassie with about 2,000 white troops, building a military road as he went, and the Ashantees fell back before him. The Prah was crossed without opposition. At Amoafu, about 22 m. from Koomassie, a severe battle

was fought on Jan. 31, in which the Ashantees were defeated with heavy loss, including their commander Amanquatia. A second battle took place at Ordahsu, 15 m. beyond, on Feb. 4, the king commanding in person. After six hours the Ashantees fled, and the British entered Koomassie. On the morning of Feb. 6 the town was fired and the troops began their homeward march. A peace was subsequently concluded, the king agreeing to pay an indemnity of 50,000 ounces of gold, to renounce the protectorate, to keep open a road to the coast, and to prohibit human sacrifices.

**GOLDEN FLEECE.** See ARGONAUTS.

**GOLDEN FLEECE, Order of the** (Span. *el toison de oro*; Fr. *ordre de la toison d'or*), one of the oldest and most important of the orders of chivalry, founded at Bruges by Philip the Good, duke of Burgundy, on occasion of his marriage with the princess Isabella of Portugal, Jan. 10, 1430, and consecrated to the Virgin Mary and the apostle Andrew. The statutes of the order declare that it takes its name from the golden fleece which the Argonauts went in search of. It is possible that it was founded in memory of Philip's father, John the Fearless, who was held a prisoner in Colchis, and that it was consecrated to St. Andrew because that apostle carried the gospel to the land of the golden fleece. Some suppose that it received the badge in consequence of the important woollen manufactures of the country. The decoration of the grand master is a chain composed of alternate flints and rays of steel, with the golden fleece fastened in the middle. The knights wear a golden fleece on a red ribbon. Its design was to maintain the honor of knighthood and protect the church, and it was sanctioned by Pope Eugenius IV. in 1433 and by Leo X. in 1516. An article of the statutes (published at Lille, Nov. 30, 1431, in the French language) ordained that if the house of Burgundy should become extinct in the male line, the husband of the daughter and heiress of the last sovereign should be grand master of the order. After the death of Charles the Bold (1477) the husband of his daughter and heiress Mary, Maximilian I. of Austria, therefore inherited the grand mastership. During the war of the Spanish succession Charles III. (afterward the emperor Charles VI.) and Philip V., the contestants for the throne of Spain, both claimed this dignity. When the former left Spain he carried the archives of the order with him, and in 1713 celebrated its revival in Vienna. Spain protested against this at the congress of Cambrai in 1724, and it was decided by the treaty of Vienna in 1725 that the regents of both states should be permitted to confer the order with similar insignia, but that the members should be distinguished as knights of the Spanish or Austrian golden fleece. After the death of Charles VI., Maria Theresa in 1741 bestowed the office of grand master upon her husband Francis I., against which Philip V. of Spain protested in the electoral assembly

at Vienna and at Frankfort. At the peace of Aix-la-Chapelle in 1748, France, England, and Holland demanded that the schism should be composed; but as Ferdinand VI. of Spain declared that the order was inseparable from the Spanish crown, the dispute has remained unreconciled, and the order continues in two branches, neither of which recognizes the other. The original device of the order was *Autrè nauray* ("I shall have no other"); but Charles the Bold changed it into *Je l'ay empri* ("I have accepted it"). The statutes ordain that the knights shall recognize no other jurisdiction but an assembly of their order under the presidency of the grand master or of a knight authorized by him, and that they shall have precedence of all persons except those of royal blood. The number of knights, originally 24, was soon increased to 31, and in 1516 to 52. In 1851 the order consisted in Austria of 6 grand crosses, 20 commanders, and 161 knights.

**GOLDEN NUMBER**, the place of a given year in the lunar cycle. It is used to determine on what day the paschal moon falls, and thus to find Easter day. The mean length of the lunar cycle agrees exactly with 19 Julian years. (See CALENDAR, LUNAR CYCLE, and YEAR.) The new moons were indicated before the reformation of the calendar by means of the lunar cycle, which restores them to the same days of the civil month, and places them on the same days in any two years that occupy the same rank in the cycle. Consequently a table of the full moon's phases for 19 years will serve for any year whatever, when we know its number in the cycle. The year preceding the commencement of our era, when the new moon fell on the 1st of January, is supposed to be the beginning of the cycle, which gives this rule for finding the golden number: Add 1 to the date and divide the sum by 19; the quotient is the number of cycles elapsed, and the remainder is the golden number. When the remainder is 0, the proposed year is the last or 19th of the cycle. The new moons determined in this manner may, however, differ from the astronomical new moons as much as two days, because the sum of the solar and lunar inequalities, compensated in the whole period, may in certain cases amount to 10°, and thereby cause the new moon to arrive on the second day before or after the mean time. The Gregorian calendar rejects the golden numbers, as they are only adapted to the Julian calendar; the suppression of the ten days rendered it necessary to place them ten lines lower, and the centenary intercalation required them to be changed every century. Their place is supplied by another set of numbers called epacts. (See EPACT.)—The golden numbers were introduced into the calendar about the year 530, but were disposed as they would have been if they had been inserted at the time of the council of Nice. It was usual to mark them in the calendar with red or gold.

**GOLDENROD** (*solidago*, Linn.), the name of numerous plants, whose showy heads of flowers, waving like golden wands, make bright and gay the sides of roads, hills, and gravelly banks in the autumn. A supposed efficacy in the plants suggested to the early botanists the name *solidago*, from Lat. *solidare*, to make firm. Although the general appearance of the racemed or else corymbed heads, which bear the florets, is diverse, yet the flowers themselves differ only from the asters in the smaller heads of (except in one species) yellow flowers. The genus is mostly North American, there being about 80 species, all of which but three or four belong to this country. The most common European species is *S. virgaurea*, with a low, terete, pubescent stem, which branches above; the lower leaves are elliptical, somewhat hairy, acutely serrate, the flower heads in thyrsoid racemes. It grows in thickets and woods, and formerly was much used in medicine. Its

Goldenrod (*Solidago Canadensis*).

principle is astringent and tonic; the leaves and flowers, however, were thought aperient. It occurs in the northern regions of America, but under very dissimilar forms. Of these, a dwarf kind, only a few inches high, with obovate or lanceolate, mostly entire leaves, and a few large flowers, is the variety which Dr. Bigelow calls *alpina*; it occurs in the alpine regions of New Hampshire, of Maine, and of New York, and on the shore of Lake Superior. A second distinct variety is *humilis*, on the rocky banks of western Vermont, Lakes Huron and Superior, and northward; and a sub-variety with larger and broader leaves, the flower heads in ample, compound racemes, the flower rays occasionally white instead of yellow, is to be met with on gravelly banks of streams at the base of the White mountains in New Hampshire. A similar but distinct species is *S. thyrsoides* (Meyer), which occurs on the wooded sides of mountains from Maine to

New York and northward. Perhaps the most interesting species is the sweet goldenrod (*S. odora*, Ait.), with a slender stem 2 to 3 ft. high, often reclined; the leaves linear-lanceolate, entire, shining, covered with pellucid dots, which secrete a delicious anisate oil; the flower heads in racemes spreading in a one-sided panicle, the flower rays rather large and conspicuous. It may be occasionally found in rich shady woods. An essence distilled from the leaves has been used to relieve spasmodic pains. One of the earliest indications of the approach of autumn is in the flowers of *S. bicolor*, or white goldenrod, the only species which has white flowers. Next comes into yellow bloom the tall Canadian goldenrod (*S. Canadensis*), and following this, the gigantic goldenrod (*S. gigantea*), and the tall goldenrod (*S. altissima*), names singularly misapplied, as the altitude of both is not unusual. Afterward may be seen *S. arguta* and other species, until the lingering florets upon the downy goldenrod (*S. nemoralis*) indicate the near approach of the cold. The goldenrods generally affect dry and sterile soils, though some are found in bogs and moist places, and range from alpine heights to the very margin of the sea, where may be seen *S. sempervirens*, with its large, thick, shining green leaves, and bold, large-rayed, and conspicuous yellow flowers, and the narrow-leaved (*S. tenuifolia*, Pursh), having very small, crowded heads of inconspicuous flowers. Several species are peculiar to the western states, as *S. Ohioensis* (Riddel) and *S. Riddellii* (Frank.), in moist meadows and grassy prairies; and others, as *S. Drummondii* (Torr. and Gray), upon rocks, in common with more ordinary ones, indicating a wide distribution of the genus.

**GOLDEN SEAL.** See PUCCOON.

**GOLDFINCH** (*fringilla carduelis*, Linn.), one of the handsomest of the European *fringillidæ*, valued as a cage bird both for its beauty, its song, and its docility. It is about 5 in. long, with an extent of wings of 9 in.; the forehead and throat are crimson; the loreal space, top of the head, and a semicircular band on the upper neck black; the hind neck and back are umber brown, passing into ochre yellow on the rump; sides of breast and flanks paler, and white below; smaller wing coverts black, secondary rich yellow; most of the quills black with white tips, except the basal half of the outer webs, which are yellow; tail black, white tipped. The female is smaller, with less crimson, pure black, and bright colors in the plumage. Like all caged birds, the goldfinch sometimes shows considerable differences in color. It will pair and produce progeny with the green linnet. Its food consists of the seeds of the thistles, grasses, and herbaceous plants, which it seeks in small flocks. Its song, which is sweet and varied, usually begins in Great Britain about the end of March and continues until July; its flight is quick and buoyant, like that of the linnet. The nest is elaborately made of the usual materials, and

lined with wool and hair; the eggs, about five, are three quarters of an inch long, of a bluish white color, with brown tinges and purplish spots. It remains in Scotland through the winter, though great numbers perish in severe seasons. The goldfinch is easily caught and

Goldfinch (*Fringilla carduelis*).

tamed, and may be taught the notes of other birds and many amusing tricks; it is a great favorite both in England and America as a cage bird.—For the American goldfinches, of the genus *chrysomitris* (Boie), see YELLOW BIRD.

**GOLD FISH** or **Golden Carp** (*cyprinus auratus*, Linn.), a native of China, but introduced into Europe early in the 17th century. In China gold fish are to be found in almost every house, and are kept either in porcelain vessels or in artificial ponds; wherever known they are prized for their beauty, elegant form, grace of motion, and docility; they are very easily kept alive in small vessels, if due attention be paid to changing the water daily. The usual color is bright orange above, lighter on the sides, and whitish beneath; the scales are large and striated; the pupils are black, and the iris silvery; the mouth is small and toothless; the dorsal fin is single, with the first two rays spinous. The colors vary exceedingly by domestication, and exhibit almost every variety of orange, purple, and silvery; the fins vary considerably, as regards the size of the dorsal and the number of the anals; triple tails are common, in which case the dorsal is frequently absent. The silver fish is a mere variety, and the dark colors are the marks of the young

Gold Fish (*Cyprinus auratus*).

fish. It is found in many ponds in New England, bearing well the severity of the winters, and breeding in great numbers when protected from other fish. Gold fish form one of the most interesting ornaments of private gardens, and are seen everywhere in the basins of the

fountains of large cities in the summer season. Their food is chiefly infusorial animalcules, with bread when in confinement; their flesh is not esteemed as food. The intensity of the colors and several of their external characters are modified by their food, and the new characters are transmitted to the offspring. In artificial ponds they are taught to come to the surface at the ringing of a bell. They will live in foul water, and a long time out of water on account of the loose structure of their gills; in ponds the spawn and young fish are often eaten by their larger comrades; their life may be prolonged to 20 or 30 years, and they will bear great extremes of heat and cold. In common with many fresh-water fish, they are attacked and sometimes destroyed by a parasitic fungus, arising from any diseased surface, and even from the healthy tissue of the gills.

**GOLD HILL**, a town of Storey co., Nevada, 1 m. S. of the centre of Virginia, and about 190 m. E. N. E. of San Francisco; pop. in 1860, 638; in 1870, 4,311, of whom 2,346 were foreigners, including 210 Chinese; in 1874, about 13,000. It is built in a deep and precipitous cañon of the Washoe range of the Sierra Nevada mountains, about 6,200 ft. above the sea, and presents a very uninviting though unique appearance. It is connected by daily lines of stages with Reno on the Central Pacific railroad, 20 m. N. W., and with Carson City, 12 m. S. W. It is situated on the line of the great Comstock lode or ledge, the most productive vein of silver and gold ever known. Some of the principal mines on the lode are within the limits of the town, including the Alpha, Imperial, Gold Hill (several small ones), Yellow Jacket, Kentuck, Crown Point, Belcher, and Overman. The Belcher mine during the 22 months previous to November, 1873, returned in dividends to the stockholders \$8,232,800, and the Crown Point mine about the same amount. There are many quartz mills and hoisting works, some of the mines being 2,000 ft. deep and requiring heavy machinery. The Virginia and Truckee railroad, connecting with Virginia, Carson City, and Reno, is used to carry ore to the crushing mills, and to supply the mines with wood, &c. The water which supplies the town is brought from the summit of the Sierra Nevada, 25 m. distant, in an iron pipe 12 inches in diameter, across the Washoe valley, 1,750 ft. below the discharging point in the pipe, and thence to Virginia and Gold Hill in a flume. There is a fine hall occupied by the miners' union, and another belonging to the odd fellows and free-masons. The town has a weekly newspaper, three public schools with an average attendance of 400 pupils, and three churches, Episcopal, Methodist, and Roman Catholic. Gold Hill was founded in 1859.

**GOLDONI, Carlo**, an Italian dramatist, born in Venice in 1707, died in Paris in 1793. He passed his childhood in the midst of festivals and theatrical performances, with which his grandfather amused his leisure at a country

seat near Venice. At the age of 8 years he wrote a sort of comic drama, and at 13 played female parts on the stage at Perugia. He studied philosophy under the Dominicans at Rimini, but deserted them to join a troop of comedians. His father, a physician, undertook to teach him his own profession, but he soon solicited an exchange from medicine to law. At 16 he was transferred from legal studies at Venice to a scholarship in the papal college at Pavia, with the design of fitting him for the church. Within a year he became accomplished in music, dancing, and fencing, and learned a little of civil and canonical law. At the close of the second year he descended the Ticino and the Po with a company of wits and men of pleasure, and arriving at Chioggia was called upon to preach. His attempt met with brilliant success, and he returned to Pavia with a reputation for eloquence. In the third year of his scholarship he composed a satire against the inhabitants of the town for an insult that they had offered to the students, and was expelled from the college. He resumed his studies of law, and in 1732 was admitted into the corps of advocates at Venice. He had already composed two comedies, and been manager of the theatre where they were produced, playing the principal parts himself; and while waiting for clients he published a medley of prose and verse under the title of *Esperienza del passato, l'astrologo dell' avvenire*, &c. He soon after went to Milan, where his comic opera the "Venetian Gondolier" was produced and applauded. In 1734 his tragedy of *Belisario* was played at Venice with overwhelming success. His second tragedy, *Rosamonda*, failed in the following year. After furnishing other pieces with various success to different strolling companies, he married in 1736, and began to write for the company of Sacchi at Venice with the design of gradually reforming the Italian theatre. His aims were to substitute human vices and follies for fantastic and frivolous adventures, to have the plays written in full instead of being only sketched by the author and in large part improvised by the actors, and to banish from the stage the traditional masks and costumes by which the Harlequin, Birghella, Pantalón, and other chief actors were distinguished. In 1739 he was appointed Genoese consul at Venice, but after two years he again resumed his wandering life. At Rimini he was appointed director of the spectacles and amusements; he passed four months in Florence, visited Siena, and was received with enthusiasm at Pisa, where he resumed for a short time the practice of law, at the same time sending to Venice some of his most successful comedies. In 1747 he returned to Venice, determined to devote himself to the stage; and at the close of the first season he had raised the theatre to which he was attached to a superiority over its rivals, and during the second year produced 16 new pieces of three acts each. The excessive labor injured his health, and to

indemnify himself he began to publish his comedies, contesting the right to do so with the manager. He had already written 120 pieces, when in 1761 he was invited to Paris, where after writing two years for the Italian theatre he was attached to the court as instructor of the daughters of the king in the Italian language, and after three years more was awarded a pension. He continued to produce comedies at intervals, the most successful of which was the *Bourru bienfaisant*. His last literary labor was writing his memoirs, which appeared first in French (Paris, 1787), and afterward in Italian (Venice, 1788); they are said by Gibbon to be more comical than his best comedies. The most striking characteristic of Goldoni as an author is his fertility, scarcely surpassed by that of Calderon and Lope de Vega. The best of his pieces are in the Venetian dialect, and his greatest merits are his theatrical skill, and the liveliness, piquancy, and humor with which he depicts the manners of all classes of society in Italy. Schlegel criticises him as deficient in depth of characterization and in novelty and richness of invention. Critical biographies of him have been written by Giovanni (Milan, 1821), Carrer (Venice, 1824), Gavi (Milan, 1826), and Meneghezzi (Milan, 1827). Among the editions of Goldoni's works may be mentioned that of Venice in 44 vols. 8vo, 1788-'95, and that of Lucca in 26 vols., 1809.

**GOLDSBOROUGH**, Louis Malesherbes, an American naval officer, born in Washington in 1805, died there, Feb. 20, 1878. He was appointed midshipman in 1812, and lieutenant in 1825. In the Seminole war he commanded a company of mounted volunteers and an armed steamer. He was made commander in 1841; took part in the Mexican war, and was afterward senior naval officer of a joint army and navy commission on the Pacific coast. He became captain in 1855, and from 1858 to 1857 was superintendent of the naval academy at Annapolis. In 1861 he was placed in command of the naval part of Burnside's expedition to North Carolina. He was made rear admiral in 1862, commanded the European Squadron in 1865-'7, and subsequently the Washington navy yard.

**GOLDSCHMIDT**, Hermann, a German painter and astronomer, of Jewish descent, born in Frankfurt, June 17, 1802, died at Fontainebleau, Sept. 11, 1866. He studied painting at Munich under Schnorr and Cornelius, and in 1836 established himself in Paris. Among his paintings are the "Cumæan Sibyl" (1844), an "Offering to Venus" (1845), "Cleopatra" and a "View of Rome" (1849), and the "Death of Romeo and Juliet" (1857). He began to devote himself to astronomy in 1847, and discovered 14 asteroids between 1852 and 1861. He also pointed out more than 10,000 stars that were wanting in the maps of the academy at Berlin, and in 1863 announced that he had observed six satellites or companion stars to Sirius, one of which had been discovered in the previous year by Alvan Clark of

Cambridge, Mass. He made his discoveries with an ordinary spyglass from his studio in an attic. The academy of sciences bestowed on him its grand astronomical prize.

**GOLDSMITH, Oliver**, an English author, born in the hamlet of Pallas or Pallasmore, county Longford, Ireland, Nov. 10, 1728, died in London, April 4, 1774. His father was a clergyman of the established church, and at the birth of his son was very poor. Oliver's childhood gave no special indications of his future greatness. An attack of smallpox from which he suffered while a child left its marks upon his naturally plain face, which, with a generally uninviting exterior, made his personal appearance especially unprepossessing. His elder brother Henry was a student at the university, and several relatives contributed to send Oliver there; and in 1744 he entered Trinity college, Dublin, as a sizar or poor scholar. At that time the position of that class of students was highly disagreeable. Their dress was peculiar and designed to indicate their poverty, and they were required to perform many of the menial services of the institution. It was with the utmost reluctance that Goldsmith submitted to these humbling conditions, and while subject to them he was "moody and desponding." He was often reduced to great straits, but by borrowing, pawning his books, and writing ballads he contrived to keep his place. In 1749 he was admitted to the degree of bachelor of arts, and took his final leave of the university. He now returned home, and after some months had been spent in aimless loiterings was persuaded to prepare for the church. The two years of his probation were spent at Lissoy and Ballymahon, among the idlers at the village inns or in desultory reading. In due time he presented himself, arrayed in a fashionable dress, part of which consisted of a pair of scarlet breeches, to the bishop of Elphin for ordination, and was rejected. He now obtained employment as tutor in a gentleman's family, where he remained a few months, when he quarrelled with the family, and so found himself once more a free man with more money than he had ever before possessed. He bought a horse, and, with £30 in his pocket, sallied out upon the world. A few weeks after he returned home as destitute as he had been six months before. A large part of his money had been paid for a passage to America, but when the ship sailed he was enjoying himself with some friends in the country. It was next determined that he should try the legal profession, and an uncle affording him the means, he set out for London with £50, which he lost in gaming in Dublin; and after remaining secreted for some time, he again returned to his friends. He was next, toward the end of 1752, sent to Edinburgh to study medicine. Two winters were devoted to hearing lectures; but near the end of his second term, burdened with debts and hunted by bailiffs, he escaped from Edinburgh and fled to the continent. He passed

nearly a year at Leyden, ostensibly hearing lectures, but really devoting most of his time to pleasure, and then, after selling his books and borrowing money from his friends, he set out for Paris, where he attended chemical lectures. After remaining there but a little while, he set out to make the tour of the continent. Taking parts of Germany and Switzerland in his way, he passed to Marseilles, and thence into Italy. How he supported himself in these wanderings is told by himself, though his accounts of this part of his life must be received with caution. He says in the story of the "Philosophical Vagabond" in the "Vicar of Wakefield": "I had some knowledge of music, with a tolerable voice, and now turned what was my amusement into a present means of subsistence. . . . Whenever I approached a peasant's house toward nightfall, I played one of my most merry tunes, and that procured me not only a lodging, but subsistence for the next day." In Italy his musical powers no longer availed him, for, he said, every peasant was a better musician than himself; but he had acquired a habit of living by expedients, and here a new one presented itself. "In all the foreign universities and convents," he continues, "there are upon certain days philosophical theses maintained against any adventitious disputant, for which, if the champion maintain with any degree of dexterity, he can claim a gratuity in money, a dinner, and a bed for the night. In this manner, therefore, I fought my way toward England, walked along from city to city, examined mankind more nearly, and, if I may so express it, saw both sides of the picture." At Padua, where he remained some months, he took his medical degree. After two years had been spent in vagrant rambles, early in 1756 he landed at Dover, friendless and penniless. How he made his way thence to the metropolis is uncertain; it is only known that "in the middle of February he was wandering without friend or acquaintance, without the knowledge or comfort of one kind face, in the lonely, terrible London streets." For two or three years after his coming to London his history is very obscure. He was for some time an assistant to a chemist, and at another he practised medicine in Southwark, acting at the same time as reader and corrector of the press for the novelist and publisher Samuel Richardson. He was also for a while an usher in a school at Peckham, a business which he seems to have especially hated. It was while thus engaged that he accidentally met with the publisher of the "Monthly Review," by whom his services were engaged in the preparation of that publication. His daily employment was to write for the review under the direction of his employer. The pages of the magazine very soon gave evidence of the acquisition that had been made to its contributors, and even the writer himself began to hope that his better days were at hand. But his path was still a rough one. A daily drudgery was required of him, alike irksome to his indo-

lence and galling to his pride. These unhappy relations of the parties could not continue long, and accordingly, at the end of five months, the engagement was discontinued by mutual consent. But this transaction was one of great importance to Goldsmith, for it brought him into his appropriate sphere, and discovered to himself and others the secret of his power. He accordingly continued to write for a variety of periodicals, but only for immediate results. At this time he was appointed physician and surgeon to one of the East India company's factories on the coast of Coromandel, but for some unexplained reason the post was afterward given to another. He then applied to the college of surgeons for the post of hospital mate, but, failing to pass the necessary examination, was rejected. In 1759 he issued his first acknowledged work, a duodecimo volume entitled "An Inquiry into the Present State of Polite Learning in Europe." This brought him into public notice, and gained him acquaintance with some of the principal men of letters of the day. In the same year he engaged in a weekly periodical called "The Bee," which met with little encouragement, and lived only eight weeks. Soon after this he agreed with the publisher of the daily "Public Ledger" to contribute some articles to that newspaper, and the famous "Chinese Letters," republished a few months after under the title of "The Citizen of the World," were the result. These consist of a series of essays on society and manners, written in the assumed character of a Chinese philosopher resident in London, in a style of great purity, and in a vein of good-natured satire. The book greatly improved both the reputation and the finances of the writer. He emerged from his garret, and took more eligible rooms in Fleet street, where he made acquaintances, among them Percy, Smollett, and Johnson, with whom he contracted a warm and lasting friendship. Burke, who had been at college with him, and Hogarth were also frequent visitors here; and here began an intimacy with Sir Joshua Reynolds which only ended with Goldsmith's life. He was admitted to membership in the famous Literary club at its institution, and lived to see many persons of distinction vainly suing for the same privilege. Goldsmith now continued his labors for the booksellers as a means of temporary subsistence. The principal work which he produced during this time was the "History of England, in a Series of Letters from a Nobleman to his Son," which, though a mere compilation, was written with a fluency and grace which won for it the praise of being "the most finished and elegant summary of English history in the same compass that had been or was likely to be written." The impressions received during his tour on the continent he now gave to the world in the form of a poem. "The Traveller" was published near the end of 1764, and worked its way slowly into popularity. "The Vicar of Wakefield"

was written simultaneously with "The Traveller," though not published till 1766. The manuscript had been sold 18 months before for £60, to save its author from the bailiffs. He next commenced writing for the stage, and in 1767 produced "The Good-Natured Man," which was acted at Covent Garden theatre the next winter. Though its success was only partial, it added to its author's reputation, and brought him the substantial reward of £500. The winter of 1768-'9 was spent in compiling a Roman history, which was published the next May, in 2 vols. 8vo. The next year he commenced the compilation of the "History of the Earth and Animated Nature," which was issued in 1774 in 8 vols. 8vo. In 1770 he published "The Deserted Village." The popularity of "The Traveller" had prepared the way for this poem, and its sale was immense. In 1771 he brought out another work on the "History of England," which in many parts was merely a reproduction of the former. Goldsmith's condition and circumstances had greatly improved with the growth of his literary reputation; but his style of living advanced even more rapidly than his resources, and his pecuniary embarrassments were daily growing upon him. The productions of his pen were in great demand, and commanded unusually large prices, but were insufficient to meet his increased expenses. Besides his large compilations and his anonymous contributions to periodicals, he was steadily occupied with the preparation of small volumes, and in original poetical composition. His second comedy, "She Stoops to Conquer," was written early in 1772, but not acted till a year later. It was coldly received by Colman, the manager of Covent Garden, but strongly sustained by Goldsmith's literary and convivial associates, and had a great success. A rich reward of fame greeted the author; and, what was more needed, its pecuniary results were highly satisfactory, though still far short of meeting his pressing necessities. In this state of his affairs, associated with the learned, the gay, and the opulent, on terms altogether honorable, he found his want of money increasing at a rate which rendered all hope of relief from his labors entirely desperate. Near the last of March, 1774, he returned from a brief visit to the country, and found himself slightly indisposed by a local disorder, which was followed by a low fever, under which the overtaxed powers of his system rapidly gave way. He was in the 46th year of his age when he died. He was interred in the burial ground of the Temple church, but no memorial was set up to indicate the place of his burial, and it is now found impossible to identify it. His friends erected a monument to his memory in Westminster abbey, for which a Latin inscription was written by Dr. Johnson; and in 1837 a marble slab with an English inscription was placed by the members of the Inner Temple in the Temple church.—Of his works not already mentioned we may cite

the "Memoirs of a Protestant condemned to the Gallies of France for his Religion," a translation from the French, and his first known publication (2 vols. 12mo, London, 1758); "Life of Voltaire," written in 1759 to accompany Purdon's translation of the *Henriade*, but published separately in a magazine; "Life of Richard Nash, Esq., of Bath" (Beau Nash), (1762); "Edwin and Angelina" (or "The Hermit"), a poem (1765); "A short English Grammar" (1766); "Beauties of English Poetry" (2 vols. 12mo, 1767); "Poems for Young Ladies" (1767); "Life of Lord Bolingbroke," originally prefixed to a dissertation on the state of parties, and reprinted separately in 1770; "Life of Thomas Parnell," prefixed to an edition of his poems (1770); "The Haunch of Venison, a Poem" (1771); "The Grecian History" (2 vols. 8vo, 1774); "Retaliation, a Poem" (4to, 1774); a translation of Scarron's *Roman comique* (1774); and "A Survey of Experimental Philosophy" (2 vols. 8vo, 1776). His essays were collected and reprinted during his lifetime. The first collection of his poems appeared in London in 1780 (2 vols. 12mo), and editions have since been issued by Newell, with remarks on the actual scene of "The Deserted Village" (4to, 1811); Mitford, in the "Aldine Poets" (12mo, 1831); Bolton Corney (8vo, 1845); E. F. Blanchard, with illustrations by Birket Foster and others (8vo, 1858), &c. His miscellaneous works have been edited by S. Rose, with a memoir by Bishop Percy (4 vols. 8vo, 1801); with a memoir by Washington Irving (4 vols., Paris, 1825); by James Prior, with an elaborate biography (6 vols. 8vo, London, 1837); with a life and notes (4 vols. 12mo, 1845); and by Peter Cunningham (4 vols. 8vo, 1855). The last two editions are the most complete and accurate that have appeared. There are numerous reprints and translations of Goldsmith's works in France and Germany, and "The Vicar of Wakefield" is there as largely used for teaching English as Caesar's "Commentaries" for Latin. Biographies of the poet have been written by Mitford, Prior, and Irving; but best of all by John Forster, "Life and Adventures of Oliver Goldsmith" (1848), enlarged as "Life and Times of Oliver Goldsmith" (2 vols., 1854), and abridged (1855). Sketches of his life were published by Sir Walter Scott in his "Lives of the Novelists," and Macaulay in the "Encyclopædia Britannica."

**GOLDSTÜCKER, Theodor**, a German orientalist, born in Königsberg about 1822, died in London, March 11, 1872. He studied in Bonn under Wilhelm von Schlegel and Christian Lassen, and in Paris under Burnouf, after which he became private tutor at the university of Berlin, and a friend of Humboldt, who often refers to him in the "Cosmos." In 1849 he removed to London, at the suggestion of Prof. Wilson, whom he assisted in the preparation of a Sanskrit-English dictionary. He became professor of Sanskrit in University college, London, president of the philological society, and member

of the Asiatic society; and in 1866 founded the Sanskrit society. He wrote for periodicals and cyclopædias, and among his works are a German translation of a Hindoo drama (1842) and a number of English translations of Hindoo poems, some of them with the original texts. He left unfinished a Sanskrit-English dictionary and grammar, and an edition of the *Mimamsa*.

**GOLDTHREAD.** See **COPRIS**.

**GOLF** (Dutch, *kolf*, a club), a Scottish game played with ball and club. The players number one or more on each side, and each is provided with a separate ball. The most skilful player is he who can land his ball in a given series of holes with the fewest strokes of his club. To place the ball in a proper position for striking off is called "teeing," and the plot on which the game is played is termed the "putting ground." The balls now used are generally made of gutta percha. The game is of very ancient date in Scotland, since there exist statutes as early as 1457 prohibiting it, lest it should interfere with archery.

**GOLGOTHA.** See **CALVARY**.

**GOLIAD**, a S. W. county of Texas, intersected by the San Antonio river; area, 900 sq. m.; pop. in 1870, 3,628, of whom 876 were colored. The surface is generally level, and the soil deep and rich. The bottom lands are particularly fertile. Stock raising is one of the chief occupations. The San Antonio and Mexican Gulf railroad passes through the N. E. part. Arapahoe college, a Presbyterian institution, is at the county seat. The chief productions in 1870 were 37,640 bushels of Indian corn, and 92 bales of cotton. There were 794 horses, 917 milch cows, 5,657 other cattle, 4,853 sheep, and 1,698 swine. Capital, Goliad.

**GOLIUS, Jacobus**, a Dutch orientalist, born at the Hague in 1596, died in Leyden, Sept. 28, 1667. He was educated at Leyden, and appointed professor of Greek at La Rochelle when 21 years old, but soon returned to Leyden. In 1622 he joined a Dutch embassy to the emperor of Morocco, in order to perfect himself in Arabic. In 1624 he succeeded Erpenius as professor of Arabic at the university of Leyden, from 1625 to 1629 travelled through the Levant, and after his return was professor of mathematics. He was a voluminous writer on oriental philology; his greatest work is his *Lexicon Arabico-Latinum* (fol., Leyden, 1653).

**GOLLNOW**, a town of Prussia, in the province of Pomerania, on the Ihna, 14 m. N. E. of Stettin; pop. in 1871, 7,273. It has two churches, copper works, and manufactories of ribbon and paper. It was formerly a Hanse town.

**GOLOVNNIN, Vasilii**, a Russian navigator, born in the government of Riazan in 1776, died in St. Petersburg in 1832. He entered the imperial navy at an early age, and soon became noted for skill and courage. In 1807 he was commissioned by Alexander I. to make a survey of the Pacific coast of the empire. He sailed from Cronstadt in command of the sloop of war Diana, and was occupied till 1811 in

examining the coasts of Kamtschatka and Russian America. In May, 1811, he sailed from Petropavlovsk in Kamtschatka to make a survey of the southern Kurile islands and the coast of Tartary. In 1803 a Russian ambassador named Resanoff had endeavored to open an intercourse with Japan, but had been repulsed, as he thought, with insult. In retaliation the ship of war which conveyed him to and from Japan plundered and burned a number of Japanese villages on the Kurile islands. These outrages excited the indignation of the Japanese, and when Golovnin with his vessel appeared in their waters, he was fired at and peremptorily ordered away. Being in want of water and provisions, he persisted in landing, and finally went on shore, July 11, with two officers, four seamen, and a Kurile interpreter, on the island of Kunashir. The Japanese received him apparently in a friendly manner, but having enticed him and his companions into a castle garrisoned by 300 or 400 soldiers, they seized the Russians and hurried them over to the large island of Yesso. They were removed thence to Hakodadi, and in September to Matsmai, the capital of Yesso, where they were kept in cages in a prison erected for them, and subjected to a continual cross-examination which was very annoying. After several months they escaped, wandered for a number of days in the forests, and were recaptured. Finally, after an imprisonment of 26 months and 26 days, Golovnin and the other Russians were given up in November, 1813. Golovnin reached St. Petersburg July 14, 1814, after an absence of seven years, was promoted, and received a pension. He was afterward sent on an exploring expedition around the world in command of the sloop of war Kamtschatka, from which he returned in 1819, and of which he published a narrative (2 vols. 4to, St. Petersburg, 1822). He wrote in Russian "Observations upon the Empire of Japan" (2 vols. 8vo, 1816), and an account of his adventures among the Japanese, both of which works have been translated into English under the title of "Memoirs of a Captivity in Japan during the years 1811, '12, and '13, with Observations on the Country and the People" (2d ed., 3 vols. 8vo, London, 1824). At the time of his death he was vice admiral and general superintendent of the Russian navy. Golovnin was an accurate observer, and his narrative is one of the most interesting of the works upon Japan. He wrote also a book containing narratives of shipwrecks and disasters at sea, which appeared in a complete edition of his works published by his son (5 vols., 1864).

**GOLTZ, Bogumil**, a German author, born in Warsaw, March 20, 1801, died in Thorn, Nov. 11, 1870. He was of German parentage, studied at the gymnasium of Königsberg and at the university of Breslau, and engaged in scientific agriculture. This proving unsuccessful, he devoted himself from 1830 to literary pursuits, settling at Thorn in 1847. His works include

*Der Mensch und die Leute* (Berlin, 1858); *Die Deutschen* (3 vols., 1860); *Feigenblätter* (3 vols., 1861-'2); *Zur Charakteristik und Naturgeschichte der Frauen* (2d ed., 1863); *Typen der Gesellschaft* (3d ed., 1864); *Die Bildung und die Gebildeten* (2 vols., 1864); *Vorlesungen* (2 vols., 1869); and *Die Weltklugheit und Lebensweisheit mit ihren correspondirenden Studien* (2 vols., 1869).

**GOMBO.** See GUMBO.

**GOMER**, the first named and probably the eldest of the seven sons of Japheth (Gen. x. 2, 3). In Ezek. xxxviii. 6, Gomer designates a people who are named in connection with Gog and Magog, apparently belonging to the Scythian family. This people is identified with the ancient Cimmerii, and by some also with the Cimbri and the more modern Celts. The latter view finds an early support in Josephus, who renders Gomer by Galatai, that is, Gauls or Celts. (See CIMBRI, and CIMMERII.)

**GOMEZ, Estevan**, a Portuguese explorer, born in the latter part of the 15th century, died in Toledo in October, 1525. He accompanied Magellan on his celebrated voyage in 1519, as pilot of the ship San Antonio. When the fleet entered the strait which now bears Magellan's name, the San Antonio was sent to explore a channel further south. Gomez, who was dissatisfied with his position, induced the crew to mutiny, and putting the captain in irons returned with the ship to Spain, where he arrived in March, 1521. After a short detention for this act, he was set at liberty, and in 1524 sailed from Corunna to search for a northwest passage to the Moluccas. He struck the American coast at New York bay, made out the direction of the Hudson river, and ran north as far as the Penobscot. Contrary to the royal orders, he carried off some of the natives as slaves, probably from the Kennebec, and returned to Spain, where *esclavos* (slaves) being mistaken for *clavos* (cloves), it was reported to the king that Gomez had actually reached the Spice islands.

**GÖMÖR**, a N. county of Hungary, bordering on the counties of Liptó, Zips, Torna, Borsod, Heves, Nógrád, and Zólyom; area, 547 sq. m.; pop. in 1869, 103,639, chiefly Magyars and Slovaks, the majority of whom are Protestants. The surface is mostly mountainous, branches of the Carpathians extending into the county. It is traversed in all directions by navigable rivers, the most important of which are the Gran, the Rima, and the Sajó. The chief occupations are mining and cattle breeding. Capital, Rima-Szombath; largest town, Rosenau.

**GOMORRAH**, one of the five cities of the plain or valley of Siddim, destroyed on account of the wickedness of its inhabitants. (See DEAD SEA.)

**GONAIVES**, a seaport town of Hayti, on the W. shore of a bay of the same name, 67 m. N. by W. of Port-au-Prince; pop. about 4,000. The streets are wide, but irregular; the houses badly constructed, and destitute of shade; and the church and military and naval hospitals are

the only public buildings of note. The harbor is commodious, and the view on the bay delightful. There are mineral springs near, and excellent public baths in the town. Coffee is the chief export; cotton and indigo are raised, but not largely exported, as formerly. Haytian independence was declared here in 1803.

**GONDAR**, a town of Abyssinia, the seat of the *abuna* or archbishop of the Abyssinian church, and formerly the residence of the *negus* or king, about 25 m. N. of Lake Tzana or Dembea; lat.  $12^{\circ} 35' N.$ , lon.  $37^{\circ} 50' E.$ ; pop. about 7,000. It is built on a hill 1,000 ft. above the lake, which is itself upward of 6,000 ft. above the sea. The town consists of a number of scattered groups of houses, occupying an area of about 11 m. in circumference. The *Debra birhan*, "hill of light," is the principal quarter, situated S. W. of the ruins of a palace of the former Abyssinian kings, built in the 16th century by the Portuguese. On the east of the town flows the Magetzeh, on the west the Gaha, which after uniting in one stream empty into Lake Tzana. The houses, of which but few are two stories high, are built of rough blocks of volcanic stone. There are 44 churches and 1,200 clergy. The churches are round, and have conical thatched roofs projecting beyond the walls, with rows of wooden pillars for support, forming a circular alley in which the women remain while the men worship within. The Jews and Mohammedans have their own temples, and are allowed considerable religious liberty. There are manufactures of cotton goods, ornaments, jewelry, parchment, saddles, parasols, and braided ware. The currency consists partly of European gold and silver coin, and partly of lumps of rock salt. Gondar was during the middle ages, and as late as the 18th century, the capital of the Abyssinian kingdom, and contained more than 50,000 inhabitants. It became afterward the capital of the independent state of Amhara, which Theodore subdued in 1853, making Gondar once more the capital of Abyssinia, which it continued to be till his death in 1868.

**GONDOKORO**, a town in the territory of the Bari negroes, on the White Nile, which is here called Yubiri or Kidi, lat.  $4^{\circ} 54' N.$ , lon.  $31^{\circ} 46' E.$  It is a station of the ivory traders, who occupy it for two months each year, after which it is deserted. It has only a few miserable huts; the country around it is a desert, and the climate unhealthy. A Catholic mission was established there in 1853 by Knoblecher, but was discontinued in 1858. In 1873 Sir Samuel Baker visited it, broke up the slave trade, and proclaimed its incorporation with the dominions of the khedive of Egypt.

**GONDOLA**, a light and swift kind of boat, used on the canals of Venice and supplying the place of carriages. They are usually 25 or 30 ft. long, 5 ft. wide in the middle, and sharp at both ends, which are curved upward, the bow being ornamented with a high serrated iron plate something like the letter S in form.

Near the middle is a small cabin for the use of passengers. Formerly immense sums were sometimes expended by the great nobles on the decoration of these cabins; and this extravagance was carried so far that it was found necessary to pass a law compelling uniformity in style, no distinction of ornament or color being permitted except in the gondolas of foreign ambassadors and in that of the patriarch, who, if

Gondola.

a cardinal, was allowed to use red silk or wool in the decoration of his cabin. Since that time all have been painted black and their cabins hung with black cloth. They are propelled sometimes by a single gondolier, standing at the stern, and sometimes by two, one at the stern and one at the bow. At the beginning of this century there are said to have been more than 6,000 gondolas in Venice, and the gondoliers formed an important body, noted for their wit and humor as well as for their skill with the oars. They were celebrated also for their singing and their recitations of passages from Tasso and Ariosto, but their songs are now seldom heard.

**GONDS**, an aboriginal tribe inhabiting the highlands of the Central Provinces of India, whence that region derives the name of Gondwana or Gundwana. The earliest authentic records represent them as already affected by intermarriage and association with the Hindoos, and within the historic period their original characteristics have been still further modified by the same influences. The true Gonds, however, appear to be allied to the Dravidian races of southern India. They are a comparatively rude people, sturdy, restless, hardy, and fearless. The skin of the Gond is brown, and his hair is straight and black. He seldom exceeds 5 ft. 2 in. in height. The entire number of Gonds now dwelling in the hill tracts of central India is estimated at over 800,000. Their condition varies greatly in different localities. Near the Hindoo boundaries large numbers of them are engaged as agricultural laborers; the inhabitants of the interior are more secluded, wild, and independent. The Raj Gonds, in the eastern part of Gondwana, have sprung from the intermixture of the aborigines and Rajpoots. The Gonds possess no written language; they are generally somewhat familiar with Hindostanee, but

usually converse among themselves in their own tongue. Their religion is a degraded sort of pantheism. While polygamy is not prohibited, it is practically of rare occurrence, as a wife cannot be obtained without a payment, either in money or services, to her family. The women engage in every sort of labor except that of the chase, in which the men are extremely expert. The chief hunters of the villages now use matchlocks in place of the bow and arrow, and the men very generally carry little axes, which they throw with such skill and precision as to kill birds and animals at a considerable distance. These axes are in fact the principal agricultural implement of the Gonds, as their simple system of cultivation consists merely in felling timber, burning it, and planting grain in the ashes. The advance of the Gonds in civilization appears to be proportional to the admixture of the Hindoo element with the aboriginal race. Where this is small, as in the interior of the highlands, the scanty means of the people for subsistence, and the constant exposure to malaria and disease, operate most powerfully against any increase of prosperity. Their general condition as a people, however, seems to be gradually improving under British rule.

**GONGORA Y ARGOTE, Luis de**, a Spanish poet, born in Cordova, Jan. 11, 1561, died there, May 23, 1627. He was the son of a distinguished lawyer, and was educated at Salamanca for his father's profession, but abandoned it for poetry. He lived in his native city poor and obscure till the age of 43, when, having entered holy orders, he was made titular chaplain to Philip III.; but after 11 years of neglect he returned to Cordova in broken health. His early poetry, consisting of ballads and odes, is remarkable for vigor and simplicity, but later in life he adopted an affected, obscure, and highly metaphorical style, which for a time became fashionable in Spain, and even in France, and was imitated by a large school of succeeding poets. It is known as the *estilo culto*, or cultivated style, and one of its most marked features was the use of obsolete and foreign words and of new and forced constructions. So unintelligible were the poems of Gongora that even in his own lifetime commentaries were written to explain them. His works were published in 1636-'46, with a commentary 1,500 pages long by Coronel, a poet of the same school (3 vols. 4to, Madrid).

**GONIATITES**, a group of fossil cephalopods, having a nautilus-like shell, but with the siphuncle dorsal as in the ammonites; the septa, or partitions between the chambers, have one or more flexures at the margin. These flexures become more and more complex, from the species of the Hamilton (middle Devonian) period, when they first appear, to those of the carboniferous period, when they disappear, being replaced in mesozoic time by the ceratites and ammonites, to which they are nearly related. The *G. Marcellensis* (Van.), from the

Marcellus shales of New York, has been found a foot in diameter. *Olymenia*, an allied genus,

Goniatites (*G. retorsus*).

had the siphuncle ventral, and the septa without a distinct dorsal lobe on the median line.

**GONIOMETER** (Gr. *γωνία*, an angle, and *μετρον*, a measure), an instrument for measuring the angles of crystals. Two kinds of goniometers are in use, one designed to measure the angles by direct application of the instrument to the faces of the crystal, and the other by the arc through which the crystal must be turned for two adjoining faces to reflect in succession the same object to the eye. The first and simplest form is the common or Haüy's goniometer. It is a graduated semicircular arc with a fixed and a movable radius, between which the crystal is placed, each radius being made to coincide with the plane of one of its faces. The angle of their opening may then be read off on the arc. This instrument cannot be depended upon for nicety of measurement. The reflecting goniometer was invented by Dr. Wollaston, and several modified forms of it have been introduced by others. It requires for its use crystals with clear faces, that can distinctly reflect the image of a dark line across a clear light, as the bar of a window sash. The instrument is made with great precision, and its graduated arc is furnished with a vernier, by which the degrees are divided into minutes. The French goniometer of Adelman combines the principles of both the common and reflecting instruments, and is much less expensive than Wollaston's.

**GONSALVO DE CORDOVA**, or Gonzalo Hernandez de Cordova, called *el Gran Capitan* (the Great Captain), a Spanish general, born at Montilla, near Cordova, March 16, 1453, died in Granada, Dec. 2, 1515. His family name was Aguilar, but his ancestors rendered such services at the conquest of Cordova that St. Ferdinand permitted them to assume the name of that city. At the court of Ferdinand and Isabella Gonsalvo attracted attention by his beauty and knightly skill and the magnificence of his living. He distinguished himself at Albuera during the war with Portugal (1479), but gained the greatest renown in the war with the Moors, which began in 1481 and ended at the beginning of 1492. In conjunction with the king's

secretary, he conducted the secret negotiation with the Moorish monarch, Abdallah or Boabdil, which resulted in the capitulation of Granada. In 1495 he was sent with a small squadron against the French who had invaded the kingdom of Naples. He landed at Messina, and thence crossed over to the mainland. In his first battle at Seminara, fought against his advice, he was defeated, but his desperate valor saved the army from destruction and King Ferdinand from capture. His subsequent operations were so successful that by the end of 1496 the French, who a year before had possessed the whole kingdom, yielded up their last fortress, and withdrew to their own country. At the request of the pope, he then laid siege to Ostia, which was held by a formidable band of freebooters, and carried it by storm. On his return to Naples the king gave him the title of duke of St. Angelo, with an estate containing 3,000 vassals. In the beginning of 1500 he was called into the field to suppress a sudden insurrection of the Moors of the Alpujarras. In May of the same year he sailed from Malaga in command of an army of 4,600 men, designed to protect Naples, which the French were preparing to invade a second time. In September, in conjunction with a Venetian fleet, he laid siege to the almost impregnable fortress of St. George in Cephalonia, and the place was carried by assault in January, 1501. Gonsalvo sailed thence to Sicily, where he was waited on by an embassy from the Venetian senate bringing him magnificent presents. Meanwhile, by a secret treaty, Louis XII. of France and Ferdinand of Spain had agreed to divide Naples between them. Gonsalvo was appointed lieutenant general of the Spanish portion, which he overran and conquered in less than a month, except Taranto, which capitulated after a long siege, March 1, 1502. The French and Spaniards speedily quarrelled about their boundaries in Naples, and in July their dispute broke into open hostilities. Gonsalvo, whose force was much inferior to that of the French, threw himself into the fortified seaport of Barletta on the Adriatic. Here, from July, 1502, to April, 1503, he sustained one of the most memorable sieges in history, conducted by the duke of Nemours and the chevalier Bayard. Having at length received by sea a small reinforcement, the Great Captain on April 28 broke forth from Barletta, gave battle to the French, and defeated them, with the slaughter of half their army, the loss of all their artillery and baggage, and most of their colors. This victory decided the war, and in a few weeks all the fortresses held by the French were taken or surrendered, with the exception of Gaëta, into which the remnant of the French army had thrown themselves. A long siege ensued, which gave time to Louis XII. to despatch into Italy one of the finest armies that France had ever sent into the field. Gonsalvo met the French on the Garigliano, near Gaëta, defeated them in several encounters, and on Dec. 29,

1503, routed them totally with great slaughter. This defeat put an end to the French attempt to conquer Naples. Gaëta surrendered Jan. 1, 1504, and by a treaty, Feb. 11, peace was restored between France and Spain, the latter power retaining Naples. Gonsalvo remained in Naples, ruling the kingdom as viceroy till 1507, when Ferdinand, suspecting that he meant to make himself independent, recalled him to Spain. Soon after his arrival there he retired to his estates near Loja, where he lived in great magnificence. In 1512 the French again made head in Italy, and Ferdinand called upon Gonsalvo to take command of an army for the protection of Naples; and when it became known that he was to command, nearly all the nobles of Spain volunteered. This enthusiasm so augmented Ferdinand's distrust that he countermanded his orders, and directed Gonsalvo to disband his levies. Three years later Gonsalvo was attacked by a quartan fever, and removed to his palace in Granada, in hopes that the climate of that city would benefit his health; but he died shortly after his arrival there. His remains were laid in a sumptuous mausoleum in a chapel of the church of St. Gerónimo.

**GONZAGA**, a town of Italy, in the province and 15 m. S. of the city of Mantua; pop. about 15,000. It was formerly fortified, and is celebrated for its old castle, the cradle of the Gonzaga family. Silk is manufactured here.

**GONZAGA**, an ancient Italian family which ruled over Mantua from 1282 to 1707. Its founder was Ludovico I. (died in 1360), and his successors branched off into several lines, prominent among which were those of the dukes of Nevers and of Guastalla. Some of the rulers of Mantua were distinguished patrons of letters and art, and made their court one of the most brilliant in Italy. They intermarried with the Medici and the Estes, and a number of the ladies, especially Cecilia (born about 1424) and Lucrezia (died 1576), were renowned for learning. Besides Ludovico III. (1444-'78), sur-named the Turk for fighting the Mussulmans, there were other gallant warriors in the family, and particularly Francesco II. (1484-1519) and Vincenzo I. (1587-1611); and celebrated as a cardinal from 1561 till his death (1566) was Francesco Gonzaga. On the extinction of the elder branch after the death of Vincenzo II. (1627), a war for the succession to the dominion of Mantua and other territories resulted in favor of Charles I., duke of Nevers. His daughter Maria became queen of Poland, and another daughter, Anna, wife of the count palatine Edward. The beauty and wit of the latter made her conspicuous in Paris at the court of Anne of Austria, and her memoirs were published in 1686. Charles IV., the last duke of Mantua (died in 1708), was dispossessed in 1707 by Austria for having sided with France in the war of the Spanish succession, Savoy taking Montferrat. A collateral branch of the family still exists, the head of which

(1874) is the marquis Guerrieri-Gonzaga, the largest land owner in the district of Gonzaga. —A pretender to the dominion over Mantua appeared in 1841, in a person styling himself Alessandro di Gonzaga, Prince Castiglione. He was a soldier of fortune, born in Dresden in 1799, and is described by some authorities as a Pole of the name of Murzynowski, and by others as a son of a Russian officer of Italian origin, and again as a son or brother of a French officer named Gonzague; and he was successively engaged in the French, Russian, and Spanish armies, and in the Polish revolution of 1830-'31. In the latter part of his life he was arrested in Paris for selling decorations, and on being released after two years by Louis Napoleon, he went to London and died in 1869. He published *Odes patriotiques*, and several pamphlets and novels.

**GONZAGA, Luigi** (St. ALOYSIUS), a saint of the Roman Catholic church, born in the castle of Castiglione, near Brescia, March 9, 1568, died in Rome, June 21, 1591. He was educated at the courts of Florence, Mantua, and Spain, entered the society of Jesus in 1585, renouncing the marquise of Castiglione in favor of his brother, and went in 1591 by order of the pope to settle the rival claims of the duke of Mantua and of his own brother to the lands of Solferino. Coming back to Rome, he found the city devastated by the plague, devoted himself to the sick, and was stricken down by the epidemic. He was beatified by Gregory XV. in 1621, and canonized in 1726 by Benedict XIII., who declared him the patron saint of colleges. His feast is celebrated on June 21. His life has been written in Italian by the Jesuit Cepari, and in French by Doriéans.

**GONZAGA, Thomas Antonio Costa de**, a Brazilian poet, called the Portuguese Anacreon, born in Porto in 1747, died in Mozambique in 1793. After studying in the university of Coimbra, Portugal, he returned in 1768 to Brazil to enter on an official career. In 1788, when he was about to be married, he became involved in a conspiracy, and was condemned to perpetual exile in an island on the coast of eastern Africa, which was commuted to ten years' banishment to Mozambique. He was attacked by fever soon after reaching Africa, from which he recovered only to fall into madness. The most interesting of his poems were composed during his captivity. They are popular alike in Brazil and Portugal, and have been often reprinted. In grace, tenderness, purity of style, and harmony of verse, he ranks among the first Portuguese poets.

**GONZALES**, a S. county of Texas, intersected by the Guadalupe river; area, 1,026 sq. m.; pop. in 1870, 8,951, of whom 3,670 were colored. It has an undulating surface, about one third of which is covered with ash, oak, and other timber. The soil is fertile, consisting chiefly of a black loam. There are rich deposits of coal and iron. Guadalupe college is at the county seat. The chief productions in

1870 were 203,591 bushels of Indian corn, 28,932 of sweet potatoes, and 2,174 bales of cotton. There were 8,977 horses, 8,833 milch cows, 77,567 other cattle, 5,790 sheep, and 22,153 swine. Capital, Gonzales.

**GOOCHLAND**, an E. county of Virginia, bounded S. by James river; area, 260 sq. m.; pop. in 1870, 10,313 of whom 6,601 were colored. The surface is undulating, and the soil, watered by numerous creeks, was formerly very fertile. Bituminous coal is found in abundance, and a little gold has been discovered. It is traversed by the James River canal. The chief productions in 1870 were 76,177 bushels of wheat, 101,402 of Indian corn, 72,630 of oats, and 405,215 lbs. of tobacco. There were 670 horses, 2,727 cattle, 3,231 swine, and 16 flour mills. Capital, Goochland.

**GOOD, John Mason**, an English physician and author, born at Epping, Essex, May 25, 1764, died in January, 1827. He began his medical education as apprentice to a surgeon at Gosport, afterward studied at Guy's hospital, and in 1784 commenced practice as a surgeon at Sudbury. He removed to London in 1793, and gained in time a large professional connection. In 1810 he delivered a course of lectures at the Surrey institute, which were afterward published under the title of "The Book of Nature." In 1812 he edited the "Letters of Junius," comprising not only the acknowledged productions of that writer, but also more than 100 letters and papers of doubtful authenticity. He was an accomplished linguist, and contributed largely to periodicals. His principal works are: "Maria, an Elegiac Ode" (1786); "Diseases of Prisons and Poorhouses" (1795); "History of Medicine as far as it relates to the Profession of an Apothecary" (1795); "Parish Workhouses" (1798, 1805); "Song of Songs, or Sacred Idyls, translated from the Hebrew, with Notes" (1803); "Triumph of Britain, an Ode" (1803); "Memoirs of Alexander Geddes" (1803); "The Nature of Things," a translation from Lucretius, with notes (2 vols. 4to, 1805-'7); "Essay on Medical Technology" (1810); "The Book of Job, literally translated from the Hebrew," with notes and a dissertation (1812); "Physiological System of Nosology" (1817); "Pantologia, or Encyclopædia comprising a General Dictionary of Arts, Sciences, and General Literature," with Olinthus Gregory and Newton Bosworth, completed in 12 vols. in 1813; "The Study of Medicine" (4 vols., 1822); and "The Book of Nature" (3 vols., 1826). His life was written by Dr. Gregory (London, 1828).

**GOODALE, Elaine and Dora.** See supplement.

**GOODALL, I. Edward**, an English engraver, born in Leeds in September, 1795, died April 11, 1870. He is known by his engravings from Turner's pictures, in which the artist's characteristics are reproduced with great fidelity. Of his smaller works, the illustrations in Rogers's "Italy" are best known. His large

line engravings of Turner's "Tivoli," "Cologne," and "Caligula's Bridge" are splendid specimens of the art. **II. Frederick**, a painter, son of the preceding, born in London, Sept. 17, 1822. At 14 years of age he received a prize from the society of arts for a drawing of Lambeth palace, and at 16 another for his first oil painting. He subsequently became a frequent exhibitor at the royal academy, of which he was elected an associate in 1852, and a member in 1863. Several of his works, such as "L'Allegro" and "The Soldier's Dream," have been engraved. His "Tired Soldier" and "Village Festival" are in the Vernon gallery.

**GOOD FRIDAY**, the anniversary of Christ's death. It is only in England that the term "good" is applied to this feast. Its ancient title was Holy Friday, or the Friday in Holy Week. The Saxons named it "Long Friday," both because of its long religious services and of its rigorous and protracted fast. The Germans term it sometimes *Stiller Freitag*, because bells and organs are silent on that day, and sometimes *Char-Freitag*, from an old word meaning penitence. As it commemorates the day on which Christ, the true paschal lamb, was slain, it was designated as "the pasch" in some of the ancient eastern churches; but the appellation of "pasch of the crucifixion," or "the sorrowful pasch," was soon universally applied to it by the Greeks, and it is still so called in the East and in several countries of western Europe. The early Christian writers mention it as a day of rigorous fasting and peculiar solemnity. The ritual observed both in the Greek and Latin churches has special reference to the circumstances of Christ's death and entombment. Hence in all large churches an altar in a separate chapel is decorated with all possible magnificence, and called "the sepulchre." Thither the consecrated host, or "body of the Lord," is borne in solemn procession on Holy Thursday, and continues to be visited throughout the day by crowds of worshippers. On Good Friday morning, after the chanting of the prophecies foretelling Christ's death and of the recital of his passion from the Gospel of St. John, takes place the "adoration" or kissing of the cross. A crucifix is placed on the steps before the high altar, and while the choir sings the *improperia*, or reproaches of the Messiah to the people who crucified him, the officiating clergy and their attendants approach barefooted, each one making three successive prostrations before they kiss the feet of the sacred image. It is then presented by the celebrant at the sanctuary railing to the veneration of the people. In England, before the reformation, this ceremony was called the creeping to the cross, as appears from a proclamation of Henry VIII.: "On Good Friday it shall be declared howe creepynge of the crosse signifyeth an humblynge of ourselfe to Christe before the crosse, and the kysynge of it a memorie of our redemption made upon the crosse." After

this ceremony the consecrated host is brought in procession from "the sepulchre" to the high altar, where it is incensed, offered to the adoration of all present, and consumed by the celebrant. This is called the "mass of the presanctified" or preconsecrated bread, as the eucharistic elements are not consecrated on that day. In honor of the redemption accomplished on Good Friday, it was customary in the early church to release public penitents from their probation and the excommunicated from their ban. The first Christian emperors, not satisfied with closing the law courts during Holy and Easter weeks, honored the anniversary of salvation by liberating from prison and recalling from exile all but the worst criminals; and also, to encourage the practice then becoming general of manumitting slaves in remembrance of Christ's death, by allowing the courts and magistrates to perfect the instruments necessary for this purpose. These customs, sanctioned by a decree of Valentinian I. in 367, were embodied by Justinian in his code. The same spirit afterward pervaded the manners and legislation of western peoples. In England and Ireland Good Friday is a legal holiday as well as a fast day. The practice of breakfasting on hot cross buns on this day is still kept up in the English cities, and is also common in the United States. In the north of England it is customary to eat herb puddings in which a principal ingredient is the "passion dock," which in fructification produces fancied representations of the cross, nails, hammer, &c. The English kings were wont in ancient times to hallow rings on Good Friday, to preserve the wearers from epilepsy. The Protestant Episcopal, Lutheran, and Reformed churches, as well as many Methodists, observe the day by fasting and special services.

**GOOD HOPE**, Cape of. See CAPE OF GOOD HOPE.

**GOODHUE**, a S. E. county of Minnesota, bordering on the Mississippi, separated from Wisconsin by Lake Pepin, and watered by Cannon river; area, about 650 sq. m.; pop. in 1870, 22,618. The surface is moderately uneven, and the soil fertile. It is traversed by the river division of the Milwaukee and St. Paul railroad. The chief productions in 1870 were 1,815,603 bushels of wheat, 209,790 of Indian corn, 825,301 of oats, 81,878 of barley, 85,390 of potatoes, 470,201 lbs. of butter, and 31,468 tons of hay. There were 6,766 horses, 6,485 milch cows, 9,021 other cattle, 6,241 sheep, and 6,671 swine; 2 manufactories of agricultural implements, 5 of carriages, 4 of barrels, 3 of furniture, 8 of saddles and harness, 5 of tin, copper, and sheet-iron ware, 1 of woollen goods, 4 saw mills, 8 flour mills, and 5 breweries. Capital, Red Wing.

**GOODRICH**. **I. Elizar**, an American clergyman, born in Wethersfield, Conn., Oct. 26, 1734, died in Norfolk, Conn., Nov. 21, 1797. He graduated at Yale college in 1752, and was tutor there in 1755. In the busiest scenes of his subsequent ministry he rarely failed to cal-

culate the eclipses of each successive year; and when the aurora borealis of 1780 made its appearance, he gave one of the fullest and most accurate accounts of it ever published, with exact drawings of the auroral arch. In 1756 he was ordained minister of the Congregational church in Durham, Conn., in which office he continued till his death. He was an active friend of the revolution, preaching the right of resistance, and urging his people to lay down their property and lives in the conflict. He published several sermons, and left behind him some hundreds of essays on difficult passages of Scripture. **II. Chauncey Allen**, an American scholar, grandson of the preceding, born in New Haven, Conn., Oct. 23, 1790, died there, Feb. 25, 1860. He graduated at Yale college in 1810, and was tutor there from 1812 to 1814. After a course of theological study he became pastor of a Congregational church in Middletown, Conn. In 1817 he was elected professor of rhetoric and oratory in Yale college, and continued in that office till 1839, when he was transferred to the professorship of pastoral theology. He published in 1814 a Greek grammar, translated chiefly from Hachenberg; this he subsequently revised and enlarged, and published under his own name. In 1832 he published "Latin Lessons" and "Greek Lessons," in which the precepts of grammar are throughout accompanied by practical exercises. During several years he edited the "Quarterly Christian Spectator." In 1828 Noah Webster, his father-in-law, intrusted to him the superintendence of the octavo abridgment of his large dictionary, and he published in 1847 greatly enlarged and improved editions of the 4to and 8vo dictionaries. In 1856 he published in 8vo the new university edition of Webster's dictionary, and in 1859 a new issue of the unabridged 4to dictionary. At the time of his death he was engaged in a thorough revision of the dictionary, which was published in 1864. **III. Samuel Griswold**, better known under the assumed name of Peter Parley, an American author, nephew of the preceding, born in Ridgefield, Conn., Aug. 19, 1793, died in New York, May 9, 1860. He engaged in the publishing business in Hartford, and, after visiting Europe in 1824, established himself as a publisher in Boston, and edited from 1828 to 1842 the "Token," an illustrated annual, to which he contributed several tales and poems. His popular Peter Parley series of juvenile books was begun soon after his removal to Boston, and gradually extended to more than 100 volumes, comprising geographies, histories, travels, stories, and various illustrations of the arts and sciences. The success of these works caused several spurious books to appear under his pseudonym. In 1841 he established "Merry's Museum and Parley's Magazine," a juvenile periodical, which he edited till 1854. In 1851 he was appointed United States consul at Paris, and while there published in French *Les États*

*Unis, aperçu statistique, historique, géographique, industriel et social*" (1852). He was also the author of "The Outcast, and other Poems" (1837; illustrated ed., 1851); " Fireside Education" (1841); "Sketches from a Student's Window;" "Recollections of a Lifetime" (1857); and "Illustrated Natural History of the Animal Kingdom" (1859). **IV. Frank Boot**, an American author, son of the preceding, born in Boston, Dec. 14, 1826. He graduated at Harvard college in 1845, and was for several years the Paris correspondent of the "New York Times," writing under the signature of "Dick Tinto." A volume made up from his letters was published in 1854, entitled "Tri-colored Sketches of Paris." He has also published "The Court of Napoleon" (1857), "Man upon the Sea" (1858), and "Women of Beauty and Heroism" (1859).

**GOOD WILL**, the interest or advantage supposed to be attached to a certain established business. Nothing can be more uncertain or intangible than this; and it was for some time a question whether the law would recognize it as of pecuniary value. But it is clear that it may have, under some circumstances, a very great pecuniary value. If a partnership be established in a certain place, and has there done business for a long time, in a way which has given general satisfaction and attracted a wide and to all appearance a permanent patronage or custom, whether this be by the excellence and variety of its stock of goods, its honesty and exactness, or its supposed wealth, this partnership has a pecuniary interest in this good will, in addition to the amount of its mere stock and capital. But, while as between partners this good will is generally considered to have a value, and will be recognized and provided for by courts of equity in settling any disputes between them, and in general passes by survivorship to the remaining partners when one or more die, yet the rules of law which enter into the adjustment of good will can hardly be considered as settled. In case of insolvency, it is however clear that a court having jurisdiction of the case will recognize it as valuable, and will take care that no partner behave in such a way as to diminish its value, and will make due orders for reducing it by sale or otherwise into the form of available assets. But when the good will of a business passes by the insolvency of the trader into the hands of assignees, the trader is no longer under any obligations to continue his exertions to increase or sustain its value, although he must do nothing to injure it.—The good will of a business is often bought and sold, and made the subject of arrangement in various ways; and it would undoubtedly be regarded as a sufficient consideration for a promise to pay money. It has been held that the sale of a business, with the stock and "good will," carried with it, by implication, a promise not to enter upon a similar business so near to the old stand as to interfere materially with the purchaser. This

would seem to be equitable, and ought to be provided for in any sale or transfer of the good will. We doubt, however, whether our courts would now infer such an agreement from a mere transfer of the good will.

**GOODWIN, Harvey.** See supplement.

**GOODWIN SANDS**, dangerous sand banks off the E. coast of Kent, England, separated from the mainland by the roadstead called the Downs, which has an average width of about  $5\frac{1}{2}$  m. The banks, which are loose and shifting, are divided by a narrow channel called the Swash, navigable for small boats. The northern portion is about  $3\frac{1}{2}$  m. long, and the southern about 10 m., the average width of each being  $2\frac{1}{2}$  m. At low water many parts are dry and firm, but with the coming of the tide the sand becomes saturated and dangerous. Lightships are stationed at their N. and S. extremities and N. of the Swash, on which bells are kept ringing in hazy weather. Many fatal shipwrecks have taken place on these sands, which are full of danger to vessels passing into the Thames or the North sea. They are said to have once formed a part of the mainland of Kent, and to have belonged to the Saxon earl Godwin shortly before the Norman conquest. They were submerged about A. D. 1200.

**GOODYEAR, Charles**, an American inventor, born in New Haven, Conn., Dec. 29, 1800, died in New York, July 1, 1860. He received only a public school education. After coming of age, he joined his father Amasa Goodyear, the pioneer in the American manufacture of hardware, in the hardware business in Philadelphia. The firm being overwhelmed by the commercial disasters of 1830, he selected as a new occupation the improvement of the manufacture of India rubber. His early experiments were carried on at New Haven, Conn., Roxbury, Lynn, Boston, and Woburn, Mass., and the city of New York. The first important improvement made by him was in New York in 1836, being a method of depriving India rubber of its adhesiveness by dipping it into a preparation of nitric acid. The nitric acid gas process, as it was called, was introduced into public use, and met with great favor, especially in the manufacture of shoes, which continued to be made by that process in great numbers at Providence, R. I., until it was superseded by the superior method of vulcanization. The beneficial effect of the nitric acid process was confined to the surface, the interior body of the gum remaining subject to all the defects of native India rubber. It did not satisfy the hopes of Goodyear, and in 1838-'9 he made at Woburn, Mass., many experiments with compounds of India rubber and sulphur. In January, 1839, he observed that a piece of India rubber, mixed with ingredients among which was sulphur, when accidentally brought in contact with a red-hot stove, was not melted, but that in certain portions it was charred, and in other portions it remained elastic though deprived of adhesiveness. The material was vul-

canized; *i. e.*, it had undergone the change produced by a high degree of artificial heat. Thus were presented the germs of the two forms of vulcanized India rubber, now commonly known as the soft and the hard compounds. From this time until his death the process of vulcanization occupied his whole attention, but he reaped no adequate pecuniary reward for his labors. The Goodyear patents, now more than 60 in number, have been very expensive in themselves, and still more so from the necessity of defending and protecting them against infringers. The first publication of the process of vulcanization was Goodyear's patent for France, dated April 16, 1844. The French laws require that the patentee shall put and keep his invention in public use in France within two years from its date. Goodyear endeavored to comply with this and with all other requirements of the French laws, and thought he had effectually done so; but the courts of France decided that he had not complied in every particular, and that therefore his patent had become void. In England he was still more unfortunate. Having sent specimens of vulcanized fabrics to Charles Mackintosh and co. in 1842, and having opened with them a negotiation for the sale of the secret of the invention or discovery, one of the partners of that firm named Thomas Hancock, availing himself of the hints and opportunities thus presented to him, rediscovered, as he affirms, the process of vulcanization, and described it in a patent for England, which was enrolled on May 21, 1844, about five weeks after the specification and publication of the discovery to the world by Goodyear's patent for vulcanization in France. The patent of Hancock, held good according to English law, thus superseded Goodyear's English patent for vulcanization, which bore date a few days later. Goodyear, however, obtained the great council medal of the exhibition of all nations at London in 1851, the grand medal of honor of the world's exhibition at Paris in 1855, and the cross of the legion of honor, presented by Napoleon III. (See CLOUTHOUSE.)

**GOOKIN, Daniel**, an American author and soldier, born in Kent, England, about 1612, died in Cambridge, Mass., March 19, 1687. He came with his father to Virginia in 1621, held with 35 men his plantation, now Newport News, against the savages during the Indian massacres of March, 1622, and removed in 1644 to Massachusetts, in consequence of his sympathy with the doctrines of the Puritans. He settled in Cambridge, and in 1656 became superintendent of all the Indians who had submitted to the government of Massachusetts, an office which he held till his death. He protected the fugitive regicides in 1661, was appointed one of the two licensers of the Cambridge printing press in the following year, became unpopular during King Philip's war by the protection which he extended to the Indians, and in 1681 was made major general of the colony. He died so poor

that John Eliot solicited from Robert Boyle a gift of £10 for his widow. His "Historical Collections of the Indians of Massachusetts" bears the date of 1674, and was first published in 1792. He is said to have written a history of New England, which is lost.

**GOOLE**, a town of Yorkshire, England, on the Ouse, 22 m. W. of Hull; pop. in 1871, 7,680. It is the terminus of the Pontefract and Goole railway, and the railway from Hull to Doncaster runs through it; and it has communication with Leeds, Manchester, and Liverpool by means of the Knottingley and Goole canal. There are here extensive docks and warehouses, and a slip for repairing vessels. Boat building, sail making, and iron founding are carried on to some extent. It contains a new church, with a lofty tower, places of worship for various dissenting denominations, and several literary and charitable institutions.

**GOONTEE**, or **Goomty** (Hin. *Gomati*), a river of British India, rising in the district of Shah-jehanpore, in a small lake, 19 m. E. of Pillibheet, lat. 28° 35' N., lon. 80° 10' E., and after a S. E. course of 482 m., in which it traverses the territory of Oude, falling into the Ganges, on its left side, in lat. 25° 29', lon. 83° 15'. The principal town on its banks is Lucknow, 308 m. from its mouth, to which it is navigable. It is wide, in the dry season 4 ft. deep, and it rises 15 ft. at Lucknow in the rainy season.

**GOOSANDER**, an American fishing duck of the subfamily *merginæ* and genus *mergus* (Linn.); besides the goosander (*M. Americanus*, Cassin), the subfamily includes the mergansers and the smew. The bird is about 27 in. long, and 3 ft. in extent of wings; the bill about 3 in., of a

Goosander (*Mergus Americanus*).

bright red color; weight 5 lbs.; the female is considerably smaller. Common names of this species are sawbill, sheldrake, and, for the female, dun diver. The feathers of the forehead extend in an acute angle on the bill; the nostrils are large, and near the middle of the bill;

the plumage is full, soft, and glossy; there is a slight crest in the male; the wings and tail are short, the latter rounded, with 18 feathers; the iris is carmine; the feet orange red in winter, vermilion in the breeding season; the bill narrow, compressed, with a conspicuous black nail, the edges with sharp recurved serrations; tarsi two thirds the length of the middle toe, much compressed. The head and neck are metallic green; lower neck and rest of body beneath creamy white, becoming salmon red; fore part of back black; lower back, rump, and tail feathers ashy gray; most of the wings creamy white, except the greater coverts, which are black at the base, forming a black bar, and the tertials narrowly edged with black; primaries black; sides with slight transverse bars. In the female the head and neck are chestnut; above ashy, salmon-colored below; the black base of the secondaries is entirely concealed, and there is less white on the wings. In the European sheldrake (*M. merganser*, Linn.) the bill is relatively longer and narrower; the elongated feathers forming the crest are longer and more erectile, and begin almost at the base of the bill; and the bar of black on the wings is concealed by the lesser coverts. The American bird was considered the same as the European, until separated by Mr. Cassin in 1853. The goosander is found throughout North America, breeding in the temperate and northern regions, in the neighborhood of both salt and fresh water; it is abundant in the fur countries. It is strong and active, a powerful swimmer, excellent diver, and rapid flier; it swims very deeply, presenting a small mark for the gunner, diving at the flash or at the click of the lock; it can run very well on land. It is very voracious, feeding on fish, mollusks, and reptiles; it dives for its prey, rising to the surface with the fish or other animal in its bill, and swallows it head foremost; its flesh is tough and oily. The nest is made near the water, of weeds and roots, and is lined with its down; it is about 7½ in. in diameter internally, and 4 in. deep; the eggs, 7 or 8, are 3 in. long by two broad, smooth, elliptical, and of a uniform dull cream color; the young of a few hours old are excellent divers. The note is a harsh croak. They are easily caught, like the loon, on hooks baited with fish. In their digestive organs, the mergansers are more allied to the divers (*colymbidæ*) than to the ducks (*anatidæ*), and seem to form a connecting link between the two.

**GOOSE**, a web-footed bird, of the order *anseræ* and family *anatidæ*, of which the typical species are in the subfamily *anserinæ*. The other subfamily consists of the *plectropterinæ*, or spur-winged geese, in which the bend of the wings is armed with a spur or blunt tubercle; it contains the genera *anseranas* (Less.), of Australia; *plectropterus* (Leach), of Africa, having a naked protuberance at the base of the culmen and a part of the neck bare; *sarkidiornis* (Eyton), of the warm regions of America, India, and Africa, having a large,

rounded, laterally compressed caruncle on the top of the bill; and *chenalopeus* (Steph.), of Africa and tropical America. Of the last the Egyptian or fox goose (*C. Egyptianus*, Linn.) is a species, bright-colored, and revered by the ancient Egyptians on account of its attachment to its young; it has been domesticated in that country.—The subfamily *anserina*, which includes the genera *cereopsis* (Lath.), *anser* (Linn.), *bernicle* (Stephens), *nettapus* (Brandt), and a few others, are characterized by a moderately long neck, bill elevated at the base, as long as or shorter than the head, narrowing to the tip, which is chiefly formed by a large nail, and region in front of the eyes feathered; the long tibia and tarsus elevate the body more than in others of the family, making them good walkers on the land, while they are also excellent swimmers; the plates on the front of the tarsus are small and hexagonal, as in the swans, and are not transverse scutellæ as in the true ducks; the colors are rarely brilliant, white, black, and gray predominating, and both sexes, as in the swans, are colored alike. In the genus *cereopsis* (Lath.) the bill is very short, with a large and broad nail; it belongs to Australia, where it wanders on the land in search of grasses, on which it principally feeds, being never seen on the water; the only species (*C. Novæ Hollandiæ*, Lath.) is of a gray color, of the size of the common goose, and is said to be easily domesticated.—The genus *anser* (Linn.) is characterized by a bill as long as the head, mostly red or orange colored; the lamellæ of the upper mandible project below the edge of the bill as conical points; the nostrils open behind the middle of the commissure; the tip of the hind toe reaches the ground. The wild goose or gray-lag of Europe (*A. ferus*, Gesn.), the original of the common domesticated race, is of a gray color, with a brown mantle undulated with gray, and an orange bill. The bean goose (*A. segetum*, Gmel.) is by some considered a distinct species, and by others a mere variety of the wild goose; the wings seem to be longer, and the forehead is marked with white spots; whether a species or a variety, the bean goose is probably more or less mixed with the former in some of the domesticated races. Wild geese seek high latitudes in the breeding season and in summer, returning to the warmer parts of Europe in the winter; they are found mostly in meadows and marshes in the interior, where they feed in the daytime on aquatic plants, grasses, and grains; they walk well, and are very light on the water, on which they generally rest during the night; they do not dive, but plunge the head under water to the extent of their long neck; they are rapid and powerful fliers, migrating in two lines meeting at an acute angle; they are not polygamous, make their nests on the ground, and are very fond of their mates; the young are able to walk as soon as born, and feed of their own accord. The flight of wild geese is performed without noise, and with an or-

der which indicates considerable intelligence; each individual keeps its place in the ranks, the male bird at the head of the triangle or line, when it becomes fatigued, retiring to the rear, and the next one coming forward to take the leading and most fatiguing position. Their sight and hearing are acute, and while they feed or sleep a sentinel is always on the watch to give the alarm at the approach of danger. The awkward gait, outstretched neck, gaping mouth, and disagreeable voice have obtained for the goose the character of stupidity, while in reality it is remarkably intelligent. The flesh is not very wholesome nor digestible. The Chinese *tehin-tehu*, or Guinea goose (*A. cygnoides*, Gmel.), called from its size the swan goose, is more than 3 ft. long; the bill is orange, with a large knob or excrescence on the forehead; under the throat is a pouch, almost bare of feathers; the color above is pale grayish brown, with paler edges; a black line on the back of the neck; anterior neck and breast yellowish brown; belly white; sides over thighs gray-brown and white; in some varieties the bill, knob, and legs are black; the throat may be wattled, and the plumage mostly or entirely white. Originally from China, they have spread extensively over Asia, Africa, and Europe, and have been imported into the United States; they mix freely with the common goose, producing fertile hybrids; they are very noisy and easily alarmed; they walk erect, with the neck much elevated, more like a swan than a goose. Among the American species of the genus is the white-fronted or laughing goose (*A. Gambelii*, Hartl.), which has been separated from the European bird (*A. albifrons*, Gmel.) on account of the greater length of the bill. The length is 28

Laughing Goose (*Anser Gambelii*).

in., and the extent of wings 5 ft.; weight about 5½ lbs. The bill and legs are red; forehead white, margined behind with blackish brown; rest of head and neck grayish brown, paler on the throat; back and sides bluish gray, feathers anteriorly tipped with brown; breast

and belly grayish white, with brownish black tints, white in the anal region; tail brown, white tipped; secondaries and end of primaries dark brown, rest of wing silvery ash, the greater coverts edged with white. This species is found over the whole of North America, but is rare along the Atlantic coast; they retire to the north in March and April, returning in October; they are not so shy as other species, and their flesh is considered a delicacy; their food consists principally of land plants. The notes are loud, resembling a laugh; hence one of their common names. The egg is  $2\frac{1}{2}$  by  $1\frac{1}{2}$  in., of a dull yellowish green color, with indistinct darker patches. The snow goose (*A. hyperboreus*, Pallas) is larger, measuring 30 in. in length and 62 in extent of wings, with a weight of nearly 7 lbs. In the adult, the bill and legs are red; the general color pure white, with the primaries black toward the end and bluish gray at the base; the young, or blue-winged geese, have a more bluish and ashy tint, with patches of dark brown, constituting the *A. caerulescens* (Linn.), which some regard as a distinct species. It is found all over North America, breeding in the far north; when young, its flesh is tender, and far superior to that of the Canada goose; those that feed on the seashore have a fishy taste. The egg is yellowish white, 3 by 2 in. The usual food consists of grasses, rushes, insects, and in the autumn berries; it mates with the common goose, though the eggs are rarely if ever hatched.—The American wild or Canada goose belongs to the genus *ber-*

Asia, and America, where they spend the summer, to the more southern parts in winter, especially South America; they feed chiefly on marine grasses and algæ, though some live far from water, eating seeds, berries, &c. The Canada goose (*B. Canadensis*, Linn.) is about 3 ft. long, with an extent of wings of 65 in., and a weight of 7 lbs. The head, neck, bill, feet, and tail are black; a large, triangular patch of white on the cheeks behind the eyes, confluent below; upper parts grayish brown, with paler edges; lower lid white; below grayish white, passing into pure white near the anal region; upper tail coverts white; primaries and rump dark brown. It is found throughout North America, and accidentally in Europe; the spring migration northward begins with the melting of the snow, from March 20 to April 30, and the return commences in the first half of September, the birds passing along the coast, but most numerous in the interior; their flight is very high, their "honk" often being heard when the bird cannot be seen, and very regular unless interrupted by fogs, storms, or unexpected accidents. The food consists of the seeds of grasses and aquatic plants, slugs and snails, worms, insects, tender blades of corn, and crustacea, shell fish, and marine plants on the seashore. They are not often found in company with other species; the senses of sight and hearing are very acute, and their stratagems for avoiding their enemies evince great cunning; they rarely dive, unless when attempting to escape, at which times both old and young quickly disappear. The males are very pugnacious during their courtship, and defend their mates against all enemies; the nest is built on the ground in some retired spot near the water, of dried plants; the eggs of the wild bird are usually about six, though the domesticated birds lay a few more; they average  $3\frac{1}{2}$  by  $2\frac{1}{2}$  in., are smooth, thick-shelled, and of a dull yellowish green color; the period of incubation is 28 days, and they have only one brood in a season; the young are able to follow their parents to the water in a day or two, but many are destroyed in spite of the watchfulness of the mother by snapping turtles, gar fish, pickerel, and birds and beasts of prey. They are shot from ambush at their feeding places, and may be attracted by living or artificial decoys; the flesh of such as have lived in the interior is very agreeable, but rather strong and fishy in the shore-fed birds. Besides man and the animals just mentioned, their worst enemies are alligators, the cougar, lynx, and raccoon, and the white-headed eagle. They are readily domesticated, and when tame are advantageously crossed with the common goose, the resulting brood being larger and more easily raised and fattened than the originals. The flesh and eggs are valuable as food, the feathers for beds, the quills for writing purposes, and their oil in domestic medicine. Hutchins's goose (*B. Hutchinsii*, Rich.), called by the gunners winter or flight goose, is 25 in.

Canada Goose (*Bernicla Canadensis*).

*nicla* (Steph.), which is characterized by a bill shorter than the head, and by the black color of the legs; the lamellæ of the upper jaw concealed by the margin of the bill; nostrils over the middle of the commissure; the hind toe elevated and rudimentary, not touching the ground. The species of this genus migrate from the high latitudes of Europe,

long, with an extent of wings of 50 in., and a weight of about  $4\frac{1}{2}$  lbs.; in its color it is precisely like the Canada goose; the eggs are pure white, 3 by 2 in.; it is found throughout the northern and western parts of America; its flesh is of excellent flavor. The *B. leucopareia* (Brandt),

Brant Goose (*Bernicla brenta*).

from the west coast of America, is about 30 in. long, with an extent of wings of about 5 ft.; it resembles the Canada goose, but is smaller, and of a darker color, especially on the under parts. The brant goose (*B. brenta*, Steph.) is about 2 ft. long, with an extent of wings of 4 ft. and a weight of  $3\frac{1}{2}$  lbs. This species may be known by the white crescent on the middle of the side of its black neck; the general color of the upper parts is brownish gray with lighter margins to the feathers; the wings and tail are darker, and the upper tail coverts white; lower parts grayish, passing into white behind. It is a salt-water bird, breeding in the north, and coming along the Atlantic coast on its return south in the middle of autumn; its flesh is considered a most savory food. It is shy, a good walker, an excellent swimmer, and, when

Barnacle Goose (*Bernicla leucopsis*).

wounded, a most expert diver; its food consists of marine plants, mollusks, and crustaceans; it is easily tamed, and in captivity thrives well on grain, and produces young; the eggs are white. It is found on the Atlantic coasts of North America and Europe. It is replaced on the Pacific

coast by the black brant (*B. nigricans*, Lawr.); the anterior part of the body of the latter is black, the rest dark plumbeous, with white patches on the throat, sides of rump, and tail coverts; the bill is wider than in the common brant. The barnacle goose (*B. leucopsis*, Bechst.) is 28 in. long, with an extent of wings of  $4\frac{3}{4}$  ft., and a weight of a little over 4 lbs.; the forehead, cheeks, and lower parts are white, the belly with a bluish tint; the crown, neck, anterior back, rump, and tail black; mantle ash-colored. It is common in winter in northern Europe, especially on the western shores of Great Britain, but is doubtful as an inhabitant of the United States; it is a salt-water species, very shy, and highly esteemed as food; the eggs are yellowish cream-colored, about 3 by 2 in. It owes its name of barnacle goose to the belief long entertained that it was produced by the barnacle, a cirriped articulate animal often found adhering to old wood; an opinion expressed so lately as 1636 by Gerard, in his "Herbalist." It has also been called tree goose from the belief that it originated from old and decayed trees.—There are several large species of geese in South America, of which the most remarkable are the antarctic (*B. antarctica*, Gmel.), the males snowy white, and the females black with transverse lines; and the Magellanic (*B. Magellanica*, Gmel.), ferruginous brown and black, with white wing coverts, and bar on tail. The painted goose (*B. Canagica*, Bon., or *picta*, Pall.), of large size, of a bluish gray color, with head, nape, and tail white, black throat with white dots, and quills with a black stripe anterior to the white tip, is common in the Aleutian islands, and is doubtless also found on the N. W. coast of the United States.—The last genus of *anserinae* is *nettapus* (Brandt), found in the lakes, rivers, and estuaries of continental India, Africa, and Australia. The bill is small and elevated, with short and widely set lamellæ; the nostrils basal; wings moderate and pointed; tail short and rounded; the species are of small size. Mr. Blyth says that "the Indian species seems totally incapable of standing or walking on the ground, but invariably flutters along in a strange, scuffling manner, like a wounded bird; they always descend into the water, never alighting on the ground of their own accord." The Coromandel goose (*N. Coromandelianus*, Gmel.), of the size of a teal, has the head and neck white with black spots; crown black; lower neck with black lines; above brown with a greenish and reddish gloss; beneath white.—Prof. Baird places the genus *dendrocygna* (Swains.) in the goose family, but most authors rank it with the *anatinae* or ducks; it is allied to the geese more than to the ducks by the elevated base and large nail of the bill, the long legs, and the hexagonal scales in front of the tarsus; he describes three species as inhabiting the United States.—The common tame goose is the European wild bird domesticated, from which it varies considerably in color,

though less than ducks and fowls do from their wild originals; it tends to a general gray color, though the vent and upper tail coverts are always white; the males are sometimes entirely white, and the females generally cinereous and gray. In England, Lincolnshire is famous for the raising of geese; on the continent, Hamburg, Bremen, and Emden, and their neighborhoods, raise the best breeds. The usual weight of a fine goose is 15 or 16 lbs., and by cramming with nourishing food this weight may be doubled; by confining the bird, to prevent motion, and employing fattening diet and stupefying substances, the body becomes loaded with fat, and the liver becomes enlarged and fatty with disease, forming the principal ingredient in the *pâtés de foie gras* so much esteemed by epicures. Geese are in the best condition for the table about Christmas time; in England the feast of St. Michael, and on the continent that of St. Martin, are almost universally celebrated by roast goose. Before the days of metallic pens, goose quills formed a considerable article of trade, the living bird being stripped once and sometimes twice a year for this purpose; the value of the feathers for beds and pillows is well known, the living birds being plucked from three to five times in a year, at which periods, if cold weather come on, many die; if well fed and cared for, a goose will yield about a pound of feathers in a season. They generally breed only once a year, laying every other day, and depositing 7 or 8 eggs; incubation is about 30 days, and the female will sometimes produce enough for three broods, if the eggs are taken away in succession; they begin to lay early, are close sitters, and careful of their young; they grow fast, are little liable to disease, and are fattened by grain in a short time; when in a locality where they can pick

Bremen Goose.

up much of their food, they are profitable to raise for their flesh and that of the goslings, for their quills, and especially for their feathers. In the United States the common tame goose of Europe, in which the ganders are white and the females gray, is the most numerous, and

perhaps as profitable as any. The white Bremen goose is of larger size, handsome, and easily raised, but less prolific and hardy. The China or tchin-tchu goose, with its variety the Guinea or African goose, is very large and swan-like, at maturity weighing 50 lbs. per pair. A cross between the last and the Bremen bird, called sometimes the mountain goose, is highly prized for the table, and attains a weight of 35 or 40 lbs. per pair; it comes to maturity early, and can be reared in 16 weeks to a weight of 14 lbs., dressed. The Canada goose is sometimes tamed, especially in northern and thinly settled localities; it mixes with the common goose, though of a different genus, and the mongrels, which are not prolific, are considered a great delicacy. The goose is a very long-lived bird, its age having been known to equal 100 years. It is probable that many wild species, in different parts of the world, might by a little care be brought into a state of domestication, and thus increase the number of these useful birds.

**GOOSEBERRY** (*ribes grossularia*, Linn.), the name of a familiar garden fruit of small size. The original species is indigenous to England, France, Germany, and Switzerland, and has been found in the Himalayas, and on the banks of the Ganges (Royle). The cultivation of the gooseberry in gardens was first successfully undertaken by the Dutch; but up to the time of Miller it had gained but little reputation as a table fruit in England. Some suppose that the name originated from the use of the berry as a sauce for the goose; but Pryor states that it comes through the German *Kreuzbeere* from the Swedish *Krusbär*, meaning "frizzle berry" and "cross berry," the last having allusion to the triple spine, which is sometimes in the form of a cross. The gooseberry is represented in the United States by several species, of which the most common is the wild gooseberry (*R. cynosbati*, Linn.), with large berries armed with long prickles like a bur, or rarely smooth-skinned; it is found from Canada to the Rocky mountains near the sources of the Platte river; its fruit is pleasant to the taste. The commonest smooth gooseberry of New England is the *R. hirtellum* (Mx.), with small, smooth, purple, sweet fruit. Another species, *R. rotundifolium* (Mx.), grows upon rocky places in western Massachusetts, and extends to Wisconsin, and southward along the mountains to Virginia; this bears a smooth-skinned, pleasant fruit. The swamp gooseberry (*R. lacustre*, Poiré) is found in mountain swamps from Massachusetts and New York to the arctic circle, and, according to Douglas, in the mountains of Oregon and northern California; this species differs from others in its many-flowered racemes; its fruit is dark purple, and is unpleasant to the taste. The cultivation of the foreign varieties of the gooseberry is somewhat difficult in this country, in consequence of dry weather in the early summer succeeding the rains of the spring; and when the atmosphere is moist,

though the soil is dry, the berries become overgrown with an insidious mildew (*erysiphe mors uva*, Schw.), which effectually prevents their perfect growth. Repeated application of a wash made with flowers of sulphur and lime will alone destroy this mildew, and save the

Gooseberry (*Ribes grossularia*).

crop; but the trouble is generally considered too great for the result. A variety or hybrid, with good-sized berries of a greenish purple color and pleasant flavor, called "Houghton's seedling," originating in the vicinity of Boston, is free from the attacks of this fungus; this variety furnishes the greater part of the fruit sold in our markets. The cluster, Downing, and mountain seedling are other American varieties. The fruit in our markets is almost invariably sold in the green state for cooking purposes. The European varieties are seldom seen in this country except in the gardens of amateurs. In some of the manufacturing towns of England the operatives have gooseberry societies and hold exhibitions, the fruit being judged by weight. The gooseberry thrives best in a rather cool and partially shaded aspect; and it has been observed that the direct rays of the sun striking upon the bushes and fruit, when grown near walls and fences, cause the berries to scald, so that they fall, so rapid is the evaporation from its succulent tissues.

**GOOSE FISH**, an acanthopteron fish of the lophioid family, which contains some of the most hideous and voracious of the class. It belongs to the genus *lophius* (Artedi), characterized by a head enormously large, broad, and flat; the body slender, smooth, with two separate dorsal fins; the mouth very wide, the lower jaw the longer, armed with numerous movable, sharp, conical, recurved teeth on the jaws, palate, vomer, and pharyngeal bones; tongue smooth; branchial rays six, and branchial arches three. Numerous fleshy appendages or *cirri* are arranged along the edge

of the lower jaw, the pectoral fins, and to the base of the tail; there are several spines upon the head, two just behind the snout, others over the eyes and at the back part of the skull; the anterior rays of the dorsal, situated on the head, are separated as two slender tentacles, the first generally with a fleshy appendage, joined to the skull by bony rings, and capable of free motion at the will of the animal. The pectorals are elongated into a kind of arm, the rays representing fingers, by which some members of the family are enabled to move as upon legs; hence Cuvier's name of *pectorales pediculati*; these fins are large and digitate at the end, and behind and beneath them are the large branchial apertures; the ventrals are stout and fleshy, considerably in front of the pectorals; the tail is stout and digitate at the end. The eyes are large and oval; the nostrils are peculiar in being placed at the end of an erectile tube, the summit of which expands like the cup of a flower, and which is directed toward any odorous object. The skeleton is fibrous rather than bony; the stomach is very large and muscular, and the intestine short; the spinal cord is as long as in other fishes, but is remarkably reduced in size below its anterior third, while the nerves which arise from it form a large bundle within the spinal canal, completely concealing the cord. There are five species described, of which the *L. Americanus* (Cuv.) and *L. piscatorius* (Linn.) are the best known. The American goose fish grows to a length of 4 or 5 ft., varying in weight from 15 to 70 lbs. Its appetite is most voracious, and it feeds upon all kinds of fish; entire sea fowl, such as gulls and ducks, have been found in its stomach; it is occasionally taken by the hook and in nets, but is good for nothing, not even its liver containing much oil. Being a poor swimmer from the feebleness of its pectoral fins, it remains hidden in the mud or sand, waving its fleshy appendages, which fishes mistake in the turbid water for food, and are thus drawn within the reach of its ca-

Goose Fish (*Lophius Americanus*).

pacious gape. From this habit of fishing, it has been called angler and fishing frog, and from its hideous appearance and immense mouth, sea devil, wide gab, and devil fish. The color of the *L. Americanus* is dark brown, sometimes in blotches, and dirty white below.

The *L. piscatorius* is not uncommon in the seas of Europe, where it grows to the length of from 3 to 5 ft.; the color is brown above, the fins darker, with the under surface white.

**GOPHER**, the common name of two very different American animals, the one composing the rodent genera *geomys* and *thomomys*, the other the large land tortoise, *testudo polyphemus*, of the southern states (see TORTOISE); where the name is used for the latter animal, the rodents are almost universally called salamanders. On account of this confusion of names, it is necessary to ascertain the region of country of a speaker or writer before it can be known whether a mammal or a reptile is referred to. In Illinois and other western states the term gopher is also given to other rodents of the genus *spermophilus* (Cuv.), which will be noticed under their proper name of PRAIRIE SQUIRREL. The rodent gophers, or pouched rats, as they are often called, constitute the subfamily *geomyina*, characterized by large external cheek pouches, hairy uncleft upper lip, molars  $\frac{1}{2}$ - $\frac{3}{4}$ , great development of temporal bones, massive skull and lower jaw, very large and thick incisors, small ante-orbital foramen far forward on the side of the muzzle, broad occiput forming the posterior wall of the skull, and remarkable contraction between the orbits, where the bones are narrower than the snout; the palate is horizontal between the molars, rising rapidly in front of them to near the incisors, leaving a deep concavity between them and the molars; the body is thick-set and clumsy, the limbs equal and very short, the claws on the fore feet enormously developed for digging purposes. They are subterranean and nocturnal animals, rarely seen, and confined to North America; they are very abundant in certain districts west of the Mississippi; their colors vary much with age and season. The genus *geomys* (Rafinesque), or *pseudostoma* (Say), in addition to the above family characters, has the anterior surface of the upper incisors marked with one or two grooves, the crown of the rootless molars with an elliptical outline, very thick zygomatic arches, the lower outline of the under jaw a curve mostly parallel to the inferior surface of the incisors, the bones of the fore leg stouter than those of the posterior, and the clavicles well developed; the eyes are small and far apart, the ears hardly perceptible; no appearance of neck, the thickest part of the animal being about the head; the opening of the mouth very small, with a chamber between the incisors and molars lined with skin and mostly covered with short hair; the lower lip tumid and very movable. The cheek pouches cover the sides of the head, extending back to the middle of the scapula, and are capable of great distention; they are well clothed with hair on the side next to the head, and on the other nearly naked; they always open outside, and never communicate with the mouth; the body is covered with soft hair; the tail is thickened, hairy, tapering toward

the tip, which is naked for about half an inch; the feet are five-toed, covered with hair above, smooth and tumid below, with a large tubercle on the palm; the fingers and toes may be completely flexed; the claws are long, curved, compressed, and sharp below, smaller, thicker, and conical on the hind feet. The species are mostly found east of the Rocky mountains, and are very abundant in Missouri, Illinois, and Iowa; they are also found in Canada, Texas, Mexico, and the gulf states, but not on the Atlantic coast north of the Savannah river. The pouched gopher (*G. bursarius*, Shaw) is from 8 to 10 in. long, the tail  $2\frac{1}{2}$  to  $3\frac{1}{2}$ , and the weight from 12 to 14 oz. The prevailing color is reddish brown above, ashy brown beneath, with the feet white; in the warm season, and in young animals, the general color is plumbeous. They burrow in sandy soils, throwing up the earth in little mounds by means of the back and shoulders; they feed on grasses, roots, nuts, &c., which they carry to their holes in their pouches; they are injurious to vegetation by eating the roots of trees, shrubs, grasses,

Pouched Gopher (*Geomys bursarius*)

and vegetables; they remain inactive in cold weather; the female brings forth from five to seven at a birth in the spring. In the region of the upper Missouri they are called muloes; the generic name given by Rafinesque means "earth mouse," and that by Say "false mouth," the one indicating its burrowing habits, the other the capacious cheek pouches. They are common in Canada, and as far as lat. 52° N. The southern gopher, Georgia hamster, or salamander (*G. pinetis*, Raf.), is a large species, having a single deep groove on the upper incisors; the fore feet are longer than the hinder, the tail naked nearly to the base, and the color above plumbeous brown, ashy white beneath; it is found in Alabama, Georgia, and Florida. Five other species are described by Prof. Baird in the "Report of the Pacific Railroad Expeditions," vol. viii., from the western states, Mexico, and Texas.—There are several species of gopher, found principally on the Pacific coast of the United States, belonging to the genus *thomomys* (Maxim.), which differs from *geomys* in the nearly smooth anterior surface of the upper incisors, in the ovate crowns of the molars, less massive skull, and the fore feet

being considerably shorter than the hind ones. The California gopher (*T. bulbivorus*, Rich.) is the largest of the genus, though an inch or two less than the *G. bursarius*; the color above is reddish chestnut brown, with dusky tips to the hairs, paler beneath, and tail grayish

California Gopher (*Thomomys bulbivorus*).

3. Fore paw. 4, 5. Nails of fore and hind feet.

white. It is very annoying to the farmer and horticulturist, and its destructive propensities have caused it to be baited with traps and poisons on all possible occasions; phosphorus and strychnine seem to be the most successful.

**GÖPPERT, Heinrich Robert**, a German botanist, born at Sprottau, July 25, 1800. He studied pharmacy and medicine, and has been since 1831 professor of botany and medicine at the university of Breslau. He has published many important works on botany and fossil flora, including *Ueber die fossilen Farnkräuter* (Breslau, 1836); *Die Gattungen der fossilen Pflanzen verglichen mit denen der Jetztzeit* (Bonn, 1841-'2); *Index Palaeontologicus* (Stuttgart, 1848-'50); *Ueber die fossile Flora der silurischen, der devonischen und untern Kohlenformation* (Jena, 1860); and *Ueber Structurverhältnisse der Steinkohle* (Breslau, 1868). His private collection of specimens of fossil flora is considered the finest in the world, and the botanical garden and museum in Breslau have become under his management model institutions.

**GÖPPINGEN**, a town of Württemberg, on the Fils, 21 m. E. by S. of Stuttgart; pop. in 1871, 8,649. It contains a fine parish church, and an old castle with a winding stone staircase, known as *Traubensteig* or "grape staircase." There is a brisk trade in wool, and manufactures of woollen and linen, toys, carriages, and other articles. About 5 m. S. of Göppingen is the watering place of Boll, with cold sulphurous springs, and a bath house belonging to the crown; and about 3 m. N. E. of the town the ruined castle of Hohenstaufen, once the seat of the Swabian house of German emperors.

**GORDIAN KNOT.** See GORDIUS.

**GORDIANUS. I. Marcus Antonius**, surnamed **AFRICANUS**, a Roman emperor, born in Rome A. D. 158, died in Carthage in 238. He was descended on his father's side from the Gracchi, and on his mother's from the emperor Trajan, and possessed more extensive estates than those of any other private citizen. He was first made consul in 213, and was afterward proconsul of Africa. In his 80th year he was compelled by the leaders of the rebellion against the procurator of Maximin to assume at Carthage the imperial title. The intelligence was welcomed by the senate, which at once proclaimed Gordianus and his son Augusti, and declared Maximin a public enemy. Meantime Capellianus, procurator of Numidia, who had recently been suspended from office by Gordianus, marched with a well trained army against Carthage. The younger Gordianus met him with undisciplined forces, and was defeated and slain; and his father thereupon died by his own hands, after a nominal reign of less than two months. **II. Marcus Antonius Pius**, emperor of Rome, grandson of the preceding, born about A. D. 224, died in 244. He was proclaimed Cæsar at Rome after the death of the two Gordians in Africa, was colleague of the two new emperors Balbinus and Maximus, and after their murder by the prætorians in 238 was proclaimed emperor by the senate and the troops. During a part of his reign he was supported by the abilities of Misitheus, whose daughter he married, and carried on a war against the Persians, whom he defeated in a series of engagements in Mesopotamia in 242. Misitheus died soon after, and was succeeded in command by Philippus, an Arabian, who, by raising discontent among the troops advancing into Persia, caused Gordianus to be murdered, and himself proclaimed emperor.

**GORDIUS**, a legendary king of Phrygia, father of Midas. He was originally a peasant, but an eagle having alighted on his yoke of oxen while he was ploughing, and remained there till evening, this was taken as a presage of the future greatness of his house. To learn the meaning of the sign, he went to consult the soothsayers of Telmessus. A prophetess whom he met at the entrance of the place gave him the necessary information concerning the sacrifices, and afterward became his wife. When their son Midas had reached the age of manhood, the country was disturbed by civil dissensions, and an oracle declared that a car would bring the people a new king, and with him the end of their disturbances. While they were deliberating, Gordius with his wife and son unexpectedly appeared on a car in the assembly, and was hailed king. According to another tradition, Midas was elected king. The new ruler consecrated the yoke of his team to Zeus Basileus in the acropolis of Gordium, and an oracle declared that whosoever should untie its artfully made knot would become master of Asia. Alexander is related to have cut it asunder with the sword on his march to Persia.

**GORDON**, a N. W. county of Georgia, watered by the Oostenaula river and several other streams; area, 330 sq. m.; pop. in 1870, 9,268, of whom 1,536 were colored. It has a hilly surface, underlying which are beds of blue limestone. The soil is fertile. The Western and Atlantic railroad traverses it. The chief productions in 1870 were 96,181 bushels of wheat, 233,785 of Indian corn, 15,827 of oats, 11,214 of sweet potatoes, 80,316 lbs. of butter, and 354 bales of cotton. There were 936 horses, 3,416 cattle, 4,056 sheep, and 7,958 swine. Capital, Calhoun.

**GORDON, George**, commonly called Lord George Gordon, an English political agitator, born in London in December, 1750, died in Newgate prison, Nov. 1, 1793. He was the third son of Cosmo George, third duke of Gordon, and at a very early age entered the navy, from which he retired in 1772. He was remarkable for his personal attractions, his winning address, and happy facility of adapting himself to the tastes of all classes. In 1774 he entered parliament for the borough of Ludgershall. For a year or two he voted with the ministry, but in 1776 vehemently opposed them in a speech in which he alleged that an attempt had been made to bribe him. The ministry subsequently endeavored to persuade him to resign his seat in parliament and accept the place of vice admiral of Scotland; an offer which he resolutely declined. From this time he ceased to act with either whigs or tories, but spoke with so much effect upon the proceedings of either side, that it became a common remark that "there were three parties in parliament, the ministry, the opposition, and Lord George Gordon." In 1779 the proposition to procure from parliament an act for the relief of Scottish Roman Catholics, similar to Sir George Saville's act passed the previous year with reference to England and Ireland, caused an extraordinary excitement; and in November a society was organized in London under the name of the "Protestant Association," of which Gordon was elected president. Early in 1780 he presented a petition praying for a repeal of Sir George Saville's act; but finding the government indifferent to the application, he convened a meeting of the association on the evening of May 29, and enjoined them to meet on the succeeding Friday (June 2) in St. George's fields and carry up their petition to parliament for the repeal of the act. On the day appointed a concourse of people, estimated at nearly 60,000, assembled in St. George's fields, and accompanied him to the houses of parliament, which they completely surrounded. The house having several times refused to take the petition into immediate consideration, Gordon addressed the mob from the top of the gallery stairs, naming the members who had spoken against the measure, and protesting that "there would be no help for the Scottish people till all the popish chapels were destroyed." At a late hour in the even-

ing they proceeded to the chapels of the Sardinian and Bavarian legations, which they sacked. On Sunday, the 4th, they renewed their violence, and from the evening of that day until the morning of Thursday, the 8th, the city was almost entirely at their mercy. The prisons were broken open, the public buildings attacked, the houses of Lord Mansfield and of many Roman Catholics pillaged and burned, and at one time on the 7th 36 fires were raging within the limits of London. On the evening of that day troops began to pour into the city from all sides, and on the next afternoon the famous "Gordon" or "no popery" riots were finally quelled, after more than 450 people had been killed and wounded by the military, exclusive of a number killed by accident. On the 9th Gordon was arrested on a charge of treason, and committed to the tower. His trial came on in February, 1781, and the prisoner, owing to his eloquent and skilful defence by Erskine and Kenyon, was acquitted on the ground that his intentions in assembling the people were not malicious or traitorous. In 1788 he was sentenced to several years' imprisonment, and to pay heavy fines, for having libelled the administration of criminal justice in England, and the queen of France. About this time he had become a proselyte to Judaism. He continued to send forth from his prison handbills and letters of an eccentric character, and petitioned the national assembly of France to procure his release, but without effect. He died of a delirious fever, having been in all probability insane during the last ten or twelve years of his life.

**GORDON, Sir John Watson**, a Scottish painter, born in Edinburgh about 1790, died in 1864. He received his professional education in Edinburgh, and devoted himself exclusively to portrait painting. Among his portraits are those of Scott, De Quincey, and Wilson. In 1850 he became president of the royal Scottish academy, and was made painter limner to the queen; and in 1851, having been knighted, he was made a member of the London academy.

**GORDON, William**, an English clergyman, born at Hitchin about 1730, died in Ipswich in October, 1807. He removed to America in 1770, was ordained minister of the third church in Roxbury in 1772, and became chaplain to the provincial congress of Massachusetts. Returning to England in 1786, he published his "History of the Rise, Progress, and Establishment of the Independence of the United States of America" (4 vols., London, 1788).

**GORE, Catharine Grace**, an English novelist, born in Nottingham in 1799, died Jan. 29, 1861. Her maiden name was Francis. In 1822 she married Capt. Charles Gore, and in the following year published her first novel, "Theresa Marchmont." This was followed by several other novels and tales, up to 1831. She passed the five succeeding years on the continent, writing little; but in 1836 she fairly began her career as an author. She brought out nearly

70 works under her own name, besides several which were published anonymously. Of her novels the best known are "Mrs. Armytage," "The Diary of a Désennuyée," "Cecil, or the Adventures of a Coxcomb," and its sequel, "Ormington, or Cecil a Peer," "The Banker's Wife," "Pin Money," "Peers and Parvenus," "Preferment, or my Uncle the Peer," "Temptation and Atonement," "Mother and Daughter," "Opera, a Tale of the Beau Monde," "Woman of Business," and "Woman of the World." Among her other works are "Paris, Picturesque and Romantic," "Sketch Book of Fashion," "Sketches of English Character," several translations from the French, among which is the "Rose Fancier's Manual," and a number of dramas. Her last work was "The Two Aristocracies" (1857).

**GORE, Christopher**, an American statesman, born in Boston, Sept. 21, 1758, died at Waltham, March 1, 1827. He graduated at Harvard college in 1776, studied law, and was soon engaged in good practice. In 1789 he was appointed the first United States district attorney for Massachusetts; in 1796 he was chosen one of the commissioners to settle the claims of the United States upon Great Britain for spoiliations, and remained in London, successfully engaged in the duties of this office, about eight years; in 1803 he acted as chargé d'affaires; in 1809 was chosen governor of Massachusetts; and in 1814 was elected to the United States senate, where he served about three years. He left the most of his property to Harvard college.

**GOREE**, a small island belonging to France, on the W. coast of Africa,  $1\frac{1}{2}$  m. S. of Cape Verd, and separated from the continent by the strait of Dacar; pop. about 5,000. It is 3 m. in circumference, and is nothing more than a basaltic rock, which in some places is several hundred feet high. The fort occupies an elevated flat near the centre of the island, and the town a sandy plain at the foot of the rock. The roadstead is well sheltered, and affords safe anchorage for eight months of the year. The climate is healthy. In 1869 the imports amounted to 10,692,000, and the exports to 7,270,000 francs; there were 578 arrivals of vessels, and 600 clearances.

**GORGES, Sir Ferdinando**, lord proprietary of the province of Maine, born in Somersetshire, England, died at an advanced age in 1647. He was a partner in the conspiracy of the earl of Essex, against whom he testified on his trial in 1601. During the war with Spain he served in the navy, and after the peace, in 1604, was appointed governor of Plymouth. When Waymouth returned in 1605 from his voyage to North America, and brought with him five Indian captives, Gorges took three of them into his house, caused them to be instructed in the English language, obtained information from them of their native country, and determined to become a proprietor of domains beyond the Atlantic. He persuaded Sir John Popham,

lord chief justice of England, to share his intentions, while at the same time influential persons in London were desiring to renew the attempts which had been made by Raleigh in Virginia. A joint application was arranged, and in 1606 the king incorporated two companies, the first called the London colony, and the second the Plymouth colony, between which was divided the territory extending 50 miles inland from the 34th to the 45th parallel N. lat. The Plymouth colony had the northern portion, which was styled North Virginia. An exploring ship was sent out by Gorges, but was captured by the Spaniards. Three ships with 100 settlers sailed from Plymouth, May 31, 1607, and reached the mouth of the Kennebec in Maine, where they began a settlement, which was abandoned the next spring. In 1614 Gorges engaged Capt. John Smith, who had already visited North Virginia (which he called New England), in the service of the Plymouth company. He set sail for New England with two ships in March, 1615, but his own was dismasted and returned to port, and Capt. Dermer in the smaller vessel made the voyage, but soon returned. Other attempts of Smith were unsuccessful, but in 1616 Gorges sent out a party, which encamped on the river Saco through the winter, and in 1619-'20 Capt. Dermer again made the voyage. In 1620 Gorges and his associates obtained a new incorporation for "the governing of New England in America," which was empowered to hold territory extending westward from sea to sea between the 40th and 48th parallels N. lat. Gorges himself united with John Mason in taking grants of the district called Laconia, bounded by the Merrimack, the Kennebec, the ocean, and "the river of Canada," and under his auspices several settlements were attempted. His son, Capt. Robert Gorges, was appointed in 1623 by the council for New England "general governor of the country." This council resigned its charter to the king in 1635, surrendering the administration of its domains to a governor general to be appointed by him, and Gorges vainly expected this appointment. He now determined to establish a miniature sovereignty on his own domain. To this end he obtained from the king a charter constituting him lord proprietary of the province of Maine, with extraordinary governmental powers, which were to be transmissible with the property to his heirs and assigns. He sent his son Thomas to be deputy governor, and the officers took an oath of allegiance to the lord proprietary. The province was divided into two counties, of which Agamenticus (now York) and Saco were respectively the principal settlements; the former received a city charter as Gorgeana in 1642. When the four New England colonies formed a confederacy in 1643, the settlements of Gorges were excluded from it, "because," says Winthrop, "they ran a different course from us both in their ministry and their civil administration," and because the proprie-

tary was then in arms in England for the king against the cause of the Puritans. On his death the people repeatedly wrote to his heirs; but as no answer was received, they at length formed themselves into a body politic for the purposes of self-government, and submitted to the jurisdiction of Massachusetts.—His grandson FERDINANDO, born in 1629, published "*America Painted to the Life*" (London, 1659), sold to Massachusetts in 1677 his proprietary rights to the province of Maine for £1,250, and died Jan. 25, 1718.

**GÖRGEY**, or **Görgei**, **Arthur**, a Hungarian general, born in the county of Zips, Feb. 5, 1818. He entered the military school at Tulu, and subsequently the royal Hungarian noble life guards at Vienna, and was appointed lieutenant in the regiment of Palatine hussars. He soon left the army to devote himself to chemical studies at Prague. He spent the spring of 1848 without any participation in the early events of the Hungarian revolution; but when the insurrections of the non-Magyar tribes in the south of Hungary had compelled the Hungarian ministry to declare the country in danger, he offered his services to the national government. In August he received the command of the national guard of the circle W. of the Theiss, and was sent to the island of Csepel, formed by the Danube, to defend that line against the Croats of Ban Jellachich. The ban having been defeated at Pákozd, and having fled toward Vienna, Görgey operated with Perczel against the Croatian corps, which finally surrendered at Ozora (Oct. 7). Kossuth then sent him as colonel to the army of the upper Danube, which was about to cross the frontier for the deliverance of Vienna; and after the defeat at Schwechat, near Vienna (Oct. 30), he made him general-in-chief of the whole army which was charged with defending the frontier. Görgey's force was unfit to maintain a long line of defence against the superior and victorious army of Windischgrätz, and on the approach of that general he abandoned the frontier and retreated toward Buda, which was also abandoned to the enemy early in 1849. Görgey then crossed the Danube at Pesth, and marched toward the Waag. German in all except name and descent, he had no sympathy with Kossuth and the other revolutionary leaders, and on reaching Waitzen issued a manifesto in the form of a "declaration of the royal Hungarian *corps d'armée* of the upper Danube," which was directed quite as much against the republican tendencies of Kossuth and his associates as it was against the unconstitutional reign of Francis Joseph, who had just been declared emperor. This manifesto, which was followed by acts of insubordination on his part, caused Görgey to be suspected of treacherous designs. He was, however, protected by the various perplexities of the government, and the sympathies of his army. But his situation was not less critical than that of the government. His army, consisting of about 15,000 men, was soon

hemmed in, in the midst of winter, among the mountain towns of the mining district. The offensive march westward was given up, and a retreat toward the upper Theiss commenced. After the defeat of Guyon at Windschacht (Jan. 21), and of Görgey at Hodries (Jan. 22), all the three divisions of the army were on the brink of destruction, and all escaped as by a miracle, effecting their junction at Neusohl. Separating again, they marched toward the northernmost Hungarian region of the Carpathians, and entered Zips, Görgey's native county, at the beginning of February. Having here been surprised at Igló on the night between Feb. 2 and 3, and suffered some considerable loss, Guyon soon after (Feb. 5) saved the army by his victory on Mount Branyiszskó over a division of Schlick's corps, which opened a junction with the Hungarian corps under Klapka on the upper Theiss. Görgey, who had neglected communication with the government at Debreczin, and disbelieved the non-official reports of the successful operations of Klapka, too late concerted with the latter a common plan of attack, and thus missed the opportunity of crushing Schlick's corps at Kaschau. Arrived in that town, Görgey received an order placing him, like Perczel and Klapka, under the Polish general Dembinski, as commander-in-chief of the united Hungarian main army. Görgey immediately began intrigues against the foreign generalissimo, which much deranged the offensive plans of the latter. Dembinski doubted the fidelity of Görgey; the latter had no confidence in the ability of his superior. The unfavorable issue of the two days' battle of Kápolna (Feb. 26, 27) was ascribed by the one to unskilful dispositions, by the other to treacherous slowness in execution. The chief officers of the army, mostly partisans of Görgey, openly declared their want of confidence in Dembinski; the government was forced to yield, and after a few weeks of interregnum Görgey was appointed general-in-chief of the united main army, which was again to take the offensive against Windischgrätz. Crossing the upper Theiss, he began his march on the line of operation chosen by Dembinski, but with greater success. The whole campaign was an uninterrupted series of victories, which destroyed the finest imperial troops in Hungary, freed Pesth, and rescued the fortress of Comorn. The road to Vienna was open, but Buda had still to be conquered. Görgey undertook the latter task, but when he had executed it (May 21) the Russian armies were already approaching the frontiers of Hungary, and the opportunity of striking a decisive blow at Austria in its capital was lost. Kossuth now conferred upon Görgey the title of lieutenant field marshal, which he refused to accept. He set himself in opposition to Kossuth's republican plans; and having strengthened his personal position by assuming also the duties of minister of war, and by the removal from his army of some of the most independent and ablest of his generals,

he recommenced the offensive against the Austrians simultaneously with the invasion of the Russians. Political rather than strategical reasons led him to choose the left bank of the Danube as a basis of operations, and he changed his plan only after a series of bloody and fruitless struggles on the Waag and Danube (June 16, 20, 21). On the right bank of the latter river his army was forced to give up Raab (June 28), and he was obliged to retreat into the fortified camp at Comorn, where he gained more glory than success in the great battle of Szőny (July 2), in which he was wounded. At this juncture, when Russians and Austrians were advancing from every quarter, a concentration of the main armies on the Theiss was resolved upon at Pesth; Mészáros received the nominal, and Dembinski the virtual command in chief; the capital was again evacuated, and Görgey was finally compelled to sacrifice his plans. Leaving a part of his army under Klapka at Comorn, he retreated toward Waitzen, where he fought (July 15) against the Russian main army under Paskevitch; but being unable to break through it, he took his direction toward the upper Theiss, and defeated the Russians on the Sajó (July 25) and on the Hernád (July 28). The division of Nagy-Sándor was soon after surprised and defeated at Debreczin (Aug. 2); and when Görgey finally reached Arad, the last appointed place of concentration, as well as the last seat of the Hungarian government, his army alone was still able to fight, all the others which had been ordered there having been defeated and dispersed; Bem had lost Transylvania. But to resist with success the overwhelming forces of Paskevitch and Haynau was now impossible. Having summoned Kossuth to resign, and been himself invested (Aug. 11) with supreme civil and military powers, Görgey informed the Russian general Rüdiger of his intention to surrender his army, relying for the fate of his men on the magnanimity of the czar. The surrender took place at Világos, Aug. 13, 1849, when 20,000 infantry and 2,000 cavalry laid down their arms. The generals and soldiers were then delivered by the Russians to the Austrians, the former to be executed at Arad (Oct. 6), the latter to serve a new term in their army. Görgey was spared at the intercession of the czar, and carried as captive to Klagenfurth, where he resumed his chemical studies, and wrote *Mein Leben und Wirken in Ungarn in den Jahren 1848 und 1849* (Leipzig, 1852; English translation, "My Life and Acts in Hungary," London, 1852). On the restoration of the Hungarian constitution in 1867, he returned to his country, and in 1869 published anonymously *Magyarország 1849-ben és 1866 után* ("Hungary in 1849 and after 1866"), a review of the situation from a politico-strategical point of view.

**GORGIAS**, a Greek rhetorician and sophist, born in Leontini, Sicily, about 487 B. C., died about 380. He was a disciple of Empedocles and Prodicus, and first appears in history in

427, when he was sent to Athens to beseech succor for the Leontines attacked by the Syracusans. He spent the remainder of his life chiefly in Greece. He not only captivated the Athenian populace by the splendor of his eloquence, but gained Alcibiades, Alcidas, Æschines, and Antisthenes for pupils or imitators. Plato gave his name to the dialogue which he composed against the sophists. The views of Gorgias were set forth in a work "On Nature," which was early lost, but of which considerable extracts still exist. A full account of it is given by Theophrastus. The book was divided into three sections. In the first he argued that nothing had any real existence; in the second, that if there were a real existence, it was not in man's power to ascertain it; in the third, that existence, even if real and ascertainable, could not be communicated. To prove these points, he made use of the conclusions of the Eleatics, which however he did not fully accept. Sextus Empiricus also gives a clear description of the work of Gorgias. The charm of his oratory is said to have consisted largely in a profusion of metaphors and a poetical choice and arrangement of words. According to Plato, he expressly declared that he did not profess to impart virtue, but only the power of speaking eloquently.

**GORGONA**, an island in the Pacific, 30 m. from the coast of the United States of Colombia, to which it belongs; lat. 2° 51' N., lon. 78° 4' W.; length from N. to S. 6 m., breadth from E. to W. 2 m. The surface is varied, now low and undulating, now swelling into mountains, one of which is 2,000 ft. above the sea. The lower portions are covered with a thick forest growth. The soil is very fertile. There are few inhabitants. It is chiefly remarkable as having been visited by Pizarro immediately prior to the conquest of Peru, and having long been a favorite resort of buccaners.

**GORGONS**, in Greek mythology, three sisters, daughters of Phoreys and Ceto, who had but one eye in common, and changed into stone whomsoever they looked upon. Homer mentions but one gorgon, which appears as a hideous phantom in Hades, and whose head, of frightful aspect, was represented on the ægis of Athena. Hesiod mentions three, Stheno, Euryale, and Medusa, who had hissing serpents for hair, brazen claws, short wings, and a single tusk-like tooth. They were placed in the garden of the Hesperides near the realm of Night, where Medusa was slain by Perseus. Virgil places the gorgons with harpies and other monsters at Pluto's palace gate.

**GORILLA**, the largest of the anthropoid apes, a native of the equatorial region of western Africa, and first introduced to the scientific world by Dr. T. S. Savage in 1847. There were vague reports by voyagers and travellers of the existence in Africa of a quadrumanous animal larger than the chimpanzee, and there were in museums portions of a creature since ascertained to be the gorilla; but naturalists

had their attention first called to it by the paper of Dr. Savage in vol. v. of the "Boston Journal of Natural History," in which he described the external characters and habits, and Prof. Jeffries Wyman described four crania and several parts of the skeleton. Dr. Savage described it as *troglodytes gorilla*; Prof. Owen called it *T. Savagei*, retaining it in the same genus with the chimpanzee; Geoffroy Saint-Hilaire established for it the genus *gorilla* in 1852, and in 1853 gave it the name of *G. gina*, which is the best known, though *G. Savagei* has a prior claim. The common names of the gorilla among the natives of the region where it is found are engeena, geena, and engeela. There are specimens of the animal, more or less complete, in the collections at Philadelphia, Boston, London, and Paris; and Du Chaillu, on his return to the United States in August, 1859, from the country about the Gaboon river, brought with him several complete specimens,

Gorilla.

male and female, both skins and skeletons, in excellent preservation, most of which are now in the London collections. Du Chaillu is the first white man who killed a gorilla with his own hand, or who had an opportunity of studying its habits in its native forests.—The skull of the male is longer and wider, but less heavy, than that of man, and the capacity of the cavity which contains the brain is less than one half of that of the most degraded human races. The most striking peculiarity is the great development of the interparietal and occipital crests and the ridges over the orbits, which give an angular outline to the skull, resembling the oranges in the first and the chimpanzee in the latter character; there is a great thickness of the orbital walls, with much space between the orbits, and a prominence on the inner wall directed outward; a noteworthy character is the coalescence of the nasal bones above, with a median suture on their lower half, the upper

portion ascending above the nasal processes of the superior maxillary and becoming contracted between them, slightly projecting as in man; the crests are much less in the female. The cranial crests, wide zygomatic arches, and massive lower jaw give indication of the powerful muscles. The dental formula is the same as in man and the higher quadrumana; the canines are enormous, the incisors very wide, the lateral ones being more pointed, and the lower molars have five tubercles instead of four. The bones of the trunk and extremities are remarkable for their size and strength; the length of the cervical spines is such that the nape is more prominent than the back of the head; the scapulæ and bones of the arm indicate the attachment of muscles in comparison with which man's seem like those of a child. The expression of the face is scowling; the nose is very flat and widely open; the ears are small; the eyes are much sunk in the head, and the lashes are short and thick; the mouth is very wide, the lips large and thin, the lower one pendulous and very movable, the chin short and receding, and the whole muzzle prominent; the face is transversely wrinkled and black. The chest is capacious, the shoulders very wide, and the abdomen everywhere projecting. The limbs are greatly developed and of immense strength; the arms are longer than in the chimpanzee, reaching far down the leg, but according to Owen, whose observations are generally confirmed by the specimens of Du Chaillu, the arms do not extend so low as the knee; while the arm and forearm are longer than in the chimpanzee, the hand is shorter, wider, and more human in its carpal and metacarpal portions and the lateral position of the thumb; from the length of the palm the fingers appear short and thick as if swollen; they are also less free, as the posterior portion of the three intermediate fingers is covered by the undivided integument. There is very little appearance of wrist, the circumference at this part being twice that of a strong man's; the fingers taper to a point, are not arched, and the nails are flat and relatively small; the fingers are about twice the circumference of man's, and the skin of the middle joint is callous from the habit of the animal of applying these surfaces to the ground when it adopts a favorite way of progression by swinging its body forward supported by and between the hands; the thumb is short, and not more than half the size of the fore finger. The posterior extremities are occasionally used alone in standing and in progression; the thigh is relatively short, and of a nearly uniform size, in its middle portion not surpassing in circumference the same part in man; the leg increases in thickness from below the knee to the ankle; the tendinous portion of the muscles is developed more than the fleshy, with a great gain in strength. The foot is longer than the hand, and is human-like also in having the three intermediate toes

about the same length, and partly united at their base by the integuments; the gorilla is essentially quadrumanous, and the posterior thumbs are largely developed, widely separated from the toes, to which they are easily opposed, and well calculated for prehension. The genus *gorilla* was established by Geoffroy Saint-Hilaire on the following characters principally: the head rounded in the young, very much elongated and depressed in the adult, with very prominent cranial crests; the peculiar conformation of the organs of sense, above detailed; the gigantic size; the proportions of the limbs, and the characters of the hands and feet; and the peculiarities of the teeth. It seems sufficiently distinct from *troglodytes niger*. It is not easy to determine the precise position of the gorilla in the quadrumanous series; in the structure of the hand and foot it comes nearer to man than the chimpanzee does; in the canines it would seem to be below even the orangs; and in the proportion of the arm and forearm it is below the chimpanzee. The very indefiniteness of its position is another argument for its separation as a genus among the quadrumana. The adult male gorilla is from 5 to 6 ft. high in its natural altitude, though after death it may be stretched beyond this; most specimens are under 6 ft., on account of the relative shortness and generally flexed position of the legs; it far surpasses man in the dimensions of the head, neck, body, and arms, and in the width of the shoulders; some are said to measure from 7 to 9 ft. from the end of one outstretched hand to that of the other; one of Du Chaillu's specimens measures 8 ft. 11 in. The general color of the hair, which is coarse and about 2 in. long on the arms, an inch on the belly, and quite short on the back and legs, is gray inclining to black. There is a black stripe about  $2\frac{1}{2}$  in. wide extending diagonally down the sides from behind the shoulder to the belly, which is entirely black. On the upper portion of the back the hair is very thin; old ones are bare in that part. On the arms the hair is black, and reversed from the wrist to the elbow; the chest is nearly bare; there are a few white hairs in the anal region; the face, hands, and feet are black; the hands are hairy as far as the division of the fingers, the palms naked and callous; the head has generally a reddish tint; on the whole the male would be called grayish and the female blackish. The young differ greatly from the adults in the shape of the head, and the females are less ferocious-looking as well as much smaller than the males.—The gorilla is found on the W. coast of Africa, both N. and S. of the equator, but especially in the wooded districts of the interior near the head waters of the Gaboon river, and along the Muni river as far E. as the Crystal mountains. It is principally an inhabitant of the woods, but though the structure of its four hands seems well adapted to climbing on trees, it is very rare that a female

or a young male is seen on them—the old males never; its favorite mode of progression is on all fours, in a shuffling manner and rolling from side to side, but with its head always erect and its face looking forward; on account of the greater length of the arms it stoops less than the chimpanzee, and is fond of thrusting these forward, with the flexed fingers on the ground, and of giving its body a half jumping, half swinging motion forward between them; when it assumes the erect posture, it flexes the arms upward or crosses them on the nape in order to counterbalance the tendency of the trunk to fall forward. Gorillas are generally seen in troops of five, four females and one male, but the old males are occasionally met wandering alone; though living in the same neighborhood as the chimpanzees, they do not associate with them. Their strength is enormous, not only in the jaws, which are able to crush the barrel of a musket, but in the hands and feet, which they use in common with their canines in attack and defence; they are able to break with ease trees three or four inches in diameter. The males are exceedingly ferocious, generally attacking man and animals intruding upon their haunts; if wounded, they are more terrible than the lion, and in this event the hunter's death is sure and speedy if his hand trembles or his gun misses fire. They approach the enemy standing, advancing a few steps at a time, pausing to beat their breasts with both hands, and roaring terribly. When near enough, they spring upon him, and destroy him with their powerful hands. One of Du Chaillu's men was eviscerated by a single blow. The story of their carrying clubs is untrue. They are perfectly untamable, in this respect differing from the chimpanzee, which, in youth at least, appreciates kind treatment. When living in troops they are shy and difficult to approach, but when mated or alone they almost invariably offer battle, and are then the most terrible of animals. When living near villages, they sometimes come at day-break to eat the plantains and sugar cane of the natives; besides these they eat nuts, berries, fruits of the oil palm and banana, the acid pulp of the *amomum*, the white portions of the leaves of the pineapple, and roots. Unlike the chimpanzee, the gorilla makes no shelter for itself. In intelligence it is considerably inferior to the chimpanzee. It exhibits great fondness for its young, of which it has one at a time. The reports of its visiting villages and carrying off negroes into the woods are mere fables. It is generally mute, but sometimes amuses itself by a sort of roaring, which, beginning low, increases till the forest echoes with its reverberations. When about to attack its enemies it gives a terrific yell, which resounds far and wide. The negroes of the interior are very fond of eating the flesh of gorillas as well as of chimpanzees and monkeys. Among the coast tribes, on the other hand, it is considered an abomination to eat the flesh

of either the gorilla or the chimpanzee, on account of their resemblance to man.

**GORITZ.** See Görz.

**GORKHAS**, the dominant people of Nepaul in India. Little is known of their history until about 1768, when, having consolidated or conquered the petty independent tribes among whom Nepaul was parcelled out, they found themselves masters of the whole of that country, and eventually of almost the entire alpine region, as it is called, of northern India. Having invaded Thibet in 1790, they were defeated by the Chinese, to whom the lamas had applied for assistance, and during a short period they remained in nominal subjection to the celestial empire; but in 1792 their independence was recognized by a commercial treaty with the East India company. A few years later they were involved in a war with the British. (See NEPAUL.) The Gorkhas are of Mongol origin, but smaller and darker than the Chinese. They are seldom over 5 ft. high, are hardy and active, and make good soldiers. They form a valuable portion of the native troops enlisted in the British army, and won the enthusiastic praise of the English officers by their uniform fidelity during the sepoy revolt of 1857-8, and their services in the field, particularly during the Delhi campaign. They are Hindoos in religion, but unlike Hindoos in appearance, customs, and freedom from caste prejudice.

**GORKUM**, or *Gorcum* (Dutch, *Gorinchem*), a fortified town of the Netherlands, province of South Holland, on the right bank of the Maas, 22 m. S. E. of Rotterdam; pop. about 10,000. It has a college, a scientific society, the ancient church of St. Vincent containing the tombs of the lords of Arkel, and the town hall adorned with remarkable paintings. It has a considerable trade in corn, hemp, butter, cheese, salmon, and Frisian horses; there are also yards for boat building, and extensive rope walks. A canal from Gorkum to Vianen unites the Leck with the Maas. Gorkum acquired importance in the 14th century, was considered the key of Holland at the beginning of the French revolution, and was ruined by an inundation in 1809. —The martyrs of Gorkum is the name given in the Roman Martyrology to 19 persons (17 priests regular and secular, and two Franciscan lay brothers) put to death by William de la Marck and his *gueux de la mer* in 1572. They were beatified by Pope Clement X. Nov. 24, 1673, and their feast is held on July 9, the anniversary of their death.

**GÖRLITZ**, a town of Prussian Silesia, situated on an eminence which overhangs the left bank of the Neisse, and on the Dresden and Breslau railway, 53 m. E. of Dresden; pop. in 1871, 42,224. It consists of the inner town, which is surrounded with walls having 11 gates, and the suburbs. The Gothic Protestant church of Sts. Peter and Paul has a famous organ. A fine Gothic building was erected for the gymnasium in 1856. The town is the seat of several scientific and literary societies. The town hall con-

tains a large library. The manufactures are linen and woollen cloth, tobacco, starch, &c. Görlitz was a city of great importance in the three centuries preceding the reformation, and the capital of Upper Lusatia; it then declined, but of late the population has rapidly increased in consequence of the flourishing industry.

**GÖRRES.** I. **Jakob Joseph von**, a German author, born in Coblenz, Jan. 25, 1776, died in Munich, Jan. 29, 1848. After the proclamation of the French republic he gave up the study of medicine to devote himself to politics. His ardent republicanism showed itself in his first writings, and caused the suppression of a periodical published by him. In 1799 he went to Paris at the head of a deputation sent by the German provinces on the left bank of the Rhine to prepare the way for a complete union with France. Bonaparte, just raised to power by the *coup d'état* of the 18th Brumaire, could not find time to confer with the German deputation, and Görres returned home with his republican hopes much weakened. After his return he was appointed professor of natural sciences in the college of Coblenz, and he soon afterward published several philosophical works, all pervaded with the prevalent idealism. In 1803 he lectured in the university of Heidelberg, where he resided till 1808, publishing *Die deutschen Volksbücher*, and editing the *Einsiedlerzeitung*. Returning to Coblenz, he published several works on Asiatic mythology and German mediæval literature. In 1814, after the fall of Napoleon, he established *Der Rheinische Mercur*, which advocated the restoration of the German empire; it was suppressed by the Prussian government in 1816. In 1820 appeared his *Deutschland und die Revolution*, warning sovereigns that a new revolution was inevitable unless God and the Catholic church were made supreme in the restored political state. In 1827, after having resided in France and Switzerland, he was appointed professor of history in the university of Munich. The difficulty which arose in 1837 between the archbishop of Cologne and the Prussian government induced him to write his *Athanasius*, in which he espoused the cause of the archbishop, and which had great influence on the Catholics of Germany. This he followed up by other writings, and he founded the periodical *Historisch-politische Blätter*, which took a leading part in Catholic literature. In 1844 he once more advocated the political union of Germany. In 1845 he was elected a member of the Munich academy of science; and he published about that time treatises on ethnology regarded as fragments of a comprehensive universal history, which he did not live to complete. His principal work is *Christliche Mystik* (4 vols., Ratisbon, 1836-'42). A complete edition of his works, edited by his daughter, has been published (8 vols., Munich, 1856-'60). A sketch of his life was published by his pupil Sepp in 1848. II. **Guido**, a German author, son of the preceding, born in Coblenz, May

28, 1805, died July 14, 1852. After the death of his father he edited the *Historisch-politische Blätter*, but is chiefly known by his poems, legendary writings, and juvenile books. Among these are: *Die Jungfrau von Orleans* (1834); *Schön Röslein* (1838); *Testkalender in Bildern und Liedern* (3 vols., 1835-'9); *Marienlieder* (1842); *Der hürrnene Siegfried und sein Kampf mit dem Drachen*, illustrated by Kaulbach (1843); *Die Gottesfahrt nach Trier und des Teufels Landsturm* (1844); and *Die arme Pilgerin zum heilige Rocke* (1846).

**GORTCHAKOFF**, a Russian princely family, descended from the royal house of Rurik, several members of which have distinguished themselves. **I. Petr**, commander of Smolensk, is celebrated for his defence of that place against the army of Sigismund III., king of Poland, from 1609 to 1611, when it was taken by assault. **II. Dimitri**, born in 1756, won a place among the poets of Russia by his odes, satires, and epistles, and died in 1824. **III. Alexander**, born in 1764, served under Suvaroff against the Turks, the Poles under Kosciuszko, and the French in the campaign of Switzerland, and subsequently with great distinction under Benning in the campaign of 1807, when he defeated Lannes at Heilsberg and fought at Friedland, acted as chief of the war ministry in 1812, was appointed general of infantry, and died in 1825. **IV. Andrei** served as major general under Suvaroff in 1799, and commanded a division during the French invasion in 1812, when he distinguished himself in the battle of Borodino; he left the army in 1828, and died in 1855. **V. Alexander**, a statesman, born July 16, 1798. He acquired experience in diplomacy under Nesselrode in various employments, and in 1824 he was appointed secretary of legation in London; in 1830 chargé d'affaires in Florence; and in 1832 councillor of the embassy at Vienna, where he often acted as ambassador during the illness or absence of his chief. In 1841 he was sent to Stuttgart, and having negotiated the marriage between the crown prince (now king) of Würtemberg and the Russian grand duchess Olga, he was in 1846 made privy councillor. In 1850 he was appointed plenipotentiary to the German diet at Frankfurt, and in 1854 he succeeded Meyendorff as ambassador in Vienna. He displayed consummate tact and ability during the Crimean war, and it was mainly through his influence that the treaty of Paris was signed by Russia (March, 1856); after which he succeeded Nesselrode as minister of foreign affairs. In 1857 he attended the emperor Alexander during his interview with Napoleon III. in Stuttgart. As the policy of France became hostile to Austria on the Italian question, he increased in friendliness toward the former. Ambitious above all to restore the prestige of Russia after the calamities of the Crimean war, he addressed in 1860 a circular despatch to the European powers appealing to the same principle of nationalities in the Two

Sicilies which Russia had always upheld in regard to the Christians of the East, and remonstrated against any foreign interference in Neapolitan affairs; at the same time disclaiming any idea of revenge for past defeats. He favored the French expedition of 1861 to Syria for the protection of the Christian population against renewed massacres; but preserving entire independence in his foreign policy, he refused to associate himself with France and Great Britain in their unfriendly attitude toward the United States after the outbreak of the civil war. During the Polish insurrection of 1863 he availed himself of the opportunity presented by the interference of foreign powers in behalf of the Poles, to vindicate the aversion of Russia to foreign dictation, and her determination to settle her internal affairs in accordance with the interests and the integrity of the empire, and without regard to the views of other nations. This course increased his popularity at home and his prestige abroad, and the emperor, who had assigned to him the title of vice chancellor in 1862, now (July, 1863) promoted him to the office of chancellor. In 1866 he succeeded in securing the complete separation of the Roman Catholic clergy of Poland from the holy see. His most brilliant achievement was begun in October, 1870, when, after an understanding with Bismarck on the subject, he availed himself of the Franco-German war to undo the injury done to Russian influence in the East by the treaty of Paris, by securing at the London conference of January, 1871, the revision of that treaty, and the formation of another (March 13) putting an end to the neutralization of the Black sea; for this the emperor conferred upon him the dignity of serene highness. In the central Asia question (1873-'4) he exhibited a desire to avoid disturbing the friendly relations with England, without, however, receding from an aggressive policy. Though suffering from the gout, he continued (1874) to preside over the chancery, but generally spends the summer in Switzerland or Germany for the benefit of his health. His eldest son, Микһаи́л, was appointed Russian minister at Bern in 1872. **VI. Petr**, a general, born in Moscow about 1790, died there in 1868. He entered the army at an early age, fought against Napoleon in the campaigns of 1807 and 1812-'14, served under Yermoloff in the Caucasus, and distinguished himself in the war against Turkey in 1828 and 1829, when he signed the peace of Adrianople. He was made governor general of western Siberia in 1839, and general of infantry in 1843, and retired from service in 1851; but reentered it on the breaking out of the Crimean war, and commanded a wing of the Russian army at the Alma and at Inkerman in 1854. He resigned in the spring of 1855, and was in 1858 appointed member of the imperial council. **VII. Mikhail**, born in 1795, died May 30, 1861. He served against the French in the campaigns of 1807 and 1812-'14, against the Swedes in 1808-'9,

and against the Turks in 1828-'9, when he led the sieges of Shumla and Silistria, distinguished himself in the war of the Polish revolution (1831) at Grochow, Ostrolenka, and the taking of Warsaw, was made general of artillery, and in 1846 military governor of Warsaw, where he subsequently often acted as lieutenant of Prince Paskevitch, whom he also accompanied on the invasion of Hungary in 1849. In 1853 he received the command of the army of invasion sent to the Danubian principalities, ceded it soon after to Paskevitch, but took it again after the raising of the siege of Silistria, and led the retreating army to Bessarabia. In 1855 he was appointed commander-in-chief in the Crimea and southern Russia, and suffered defeat on the Tchernaya, but greatly distinguished himself by the gallant defence of Sebastopol, as well as by the skilful retreat to the North fort after the fall of the fortress. In 1856, after the death of Paskevitch, he was appointed governor of Poland by Alexander II., and he was carrying out that emperor's conciliatory measures at the time of his death.

**GORTON, Samuel**, a New England religious enthusiast, the first settler of Warwick, R. I., born in Gorton, England, about 1600, died in Rhode Island in November or December, 1677. He did business in London as a clothier till 1636, when he embarked for New England, and settled at Boston, and afterward at Plymouth, where he began to preach such peculiar doctrines that he was banished from the colony on a charge of heresy. With a few followers he went to Rhode Island, which had recently been settled by exiles from Massachusetts Bay; but falling again into trouble, he was publicly whipped for calling the justices "just asses" and for other contemptuous acts, and was forced to seek an asylum with Roger Williams in Providence, about 1641. Here he made himself so obnoxious that in November of that year a petition was addressed to the authorities of Massachusetts praying that Gorton and his company might be "brought to satisfaction." That colony having acquired a nominal jurisdiction over Pawtuxet, where Gorton had settled, he was summoned to Boston in September, 1642; but he refused to recognize the jurisdiction thus assumed, and about the same time removed to Shawomet, on the W. side of Narragansett bay, where he purchased land from the sachem Miantonomo. But in June, 1643, two inferior sachems contested his claims to the land, and applied to the general court at Boston for assistance. A body of 40 soldiers was consequently marched to Shawomet, and Gorton and ten of his disciples were carried to Boston, where, the question of the land being laid aside, they were put on trial for their lives as "damnable heretics." Gorton and six others were found guilty, and sentenced to confinement and hard labor in irons. In March, 1644, they were released, and ordered to leave the colony within 14 days. Gorton then went to England to obtain re-

dress, and having procured a letter of safe conduct from the earl of Warwick to the Massachusetts magistrates, and an order that his people should be allowed peaceable possession of their lands at Shawomet, he returned in 1648 to his colony, which he named after the earl. Though Massachusetts did not relinquish her claim over the Shawomet settlement until some years later, Gorton's remaining years seem to have passed quietly. He discharged many important civil offices, and on Sundays used to preach to the colonists and Indians. It is difficult to determine what were his religious opinions. He condemned a clergy and all outward forms, and held that by union with Christ believers partook of the perfection of God, that Christ is both human and divine, and that heaven and hell have no existence save in the mind. He published "Simplicities Defence against seven-headed Policy," a vindication of his course in New England (4to, London, 1646; reprinted in the collections of the Rhode Island historical society); "An Incorruptible Key composed of the CX. Psalme" (1647); "Saltmarsh returned from the Dead" (1655); "An Antidote against the common Plague of the World" (1657); "Certain Copies of Letters," &c. He also left in manuscript a commentary on a part of the Gospel of St. Matthew.—See his life by J. M. Mackie in Sparks's "American Biography."

**GORTYNA**, an ancient town of Crete, a little S. of the centre of the island, on a plain watered by the Lethæus. It was 90 stadia from the Libyan sea, on which it had two ports, Lebena and Metallum. It was next in importance and splendor to Cnossus, in alliance with which it early reduced all the rest of the island to subjection; but it was afterward at war with Cnossus, and also with Cydonia, against which Philopemen commanded its forces for several years. The site of Gortyna is thought to be near the modern Hagios Dheka. The caverns in the neighborhood have been described by Savary and Tournefort, and Captain Spratt sees in them the labyrinth of Minos.

**GÖRTZ, Georg Heinrich**, baron, a Swedish statesman, born in Germany, executed in Stockholm in March, 1719. He belonged to an ancient family, whose original name was Schlitz. He became minister of Holstein, and was sent in 1706 on a mission to Charles XII., who made him his minister of finance and afterward prime minister. In both positions he evinced rare abilities, as well as great unconcern in the choice of his means. He was endeavoring to restore the fallen fortunes of Sweden by an extraordinary diplomatic combination (see CHARLES XII.) when the king was killed at the siege of Frederikshald (1718), and he was arrested and sentenced to the block by Ulrica Eleonora and her husband Frederick of Hesse, who succeeded to the Swedish throne. The pretext for his execution was that he had mismanaged the finances and goaded on Charles to fatal enterprises.

**GORUCKPOOR.** **I.** A district of the North-west Provinces, British India, bounded N. by Nepaul, W. and S. W. by Oude; area, 7,346 sq. m.; pop. in 1871, 2,044,281. The surface is generally level, but broken in the E. and S. E. parts by ridges of low steep hills. The principal rivers are the Gogra, Gunduk, and Raptee, which have a S. E. course. The district also abounds in shallow lakes. The soil is rendered fertile by careful irrigation. The inhabitants are poor, and agriculture is almost the only branch of industry. The district was ceded to the British in 1801 by the vizier of Oude, in commutation of subsidy. **II.** The principal town of the district, on the left bank of the Raptee, here crossed by a ferry 600 ft. long, 104 m. N. by E. of Benares and 430 m. N. W. of Calcutta; pop. about 40,000. It is surrounded by forests and plantations, and during the rainy season is often encompassed by water.

**GÖRZ, or Goritz.** **I.** A circle of Cisleithan Austria (generally called Görz and Gradisca), forming with Istria and Trieste the Littoral province, but having its own diet; area, 1,143 sq. m.; pop. about 200,000, of whom 66 per cent. are Slovans, 25 per cent. Friulians, 7 per cent. Italians, and the remainder Germans. In the middle ages the district belonged to the counts of Tyrol; it was united with the possessions of the house of Austria by Maximilian I., about 1500. **II.** The capital of the circle, on the Isonzo, 22 m. N. N. W. of Trieste; pop. in 1869, 16,823. It consists of two parts, the upper or old town, and the lower or new town. The upper is fortified and contains the castle of the former counts of Tyrol and Görz. It is the seat of an archbishop and of a central episcopal seminary for all the dioceses of the Littorale, and has a deaf and dumb institute and a chamber of commerce and industry. The principal manufactures are leather, sugar, and silk. Charles X., the exiled king of France, died here in 1836, and his son the duke of Angoulême in 1844.

**GÖSCHEN, George Joachim**, an English statesman, born in London in 1831. His father, who died in 1866, was a German merchant doing business in London. The son was educated at Rugby and afterward at Oriel college, Oxford, but did not graduate on account of his scruples against taking certain prescribed oaths. In 1853 he became a partner in his father's commercial house, and gave special attention to financial questions. In 1863 he published "The Theory of Foreign Exchanges," which is regarded as a standard work. In the same year he was returned to parliament for the city of London, and took a prominent part in the movement for the abolition of religious tests and for throwing the universities open to dissenters. In July, 1865, under the Palmerston ministry, he was made vice president of the board of control, in November, under Russell, a member of the privy council, and in January, 1866, chancellor of the duchy of Lan-

caster. In June, with the other members of the ministry, he retired from office. On the accession of the Gladstone ministry in December, 1868, he entered the cabinet as president of the poor-law board, and in March, 1871, was made first lord of the admiralty. He resigned with the other ministers in February, 1874.

**GOSHAWK**, a bird of prey of the family *falconidae*, subfamily *accipitrinae*, and genus *astur* (Lacép.). The bill is short, broad at the base, with the culmen elevated and arched; the tip acute, with the lateral margins festooned in the middle; the nostrils large and in the basal cere; wings reaching to the middle of the tail, the third, fourth, and fifth quills nearly equal and longest; the tail long and broad; tarsi rather longer than middle toe, covered with broad transverse scales in front and behind; toes long, strong, and well padded below; claws strong, long, and curved. Gray describes 13 species, which are found throughout the world. The form is rather long and slender, the wings comparatively short, and the legs and tail long; they fly very swiftly and strongly, and always strike their prey while on the wing; they lurk about poultry yards, seize a duck or a chicken, and are out of shot before the farmer is aware of his loss; they also prey upon wild ducks, grouse, pigeons, hares, rabbits, squirrels, and other animals of this size; they build their nests on lofty trees, and lay from two to four eggs. The only species in the United States is the American goshawk (*A. atricapillus*, Wils.), found all over North America, but most abundant in the north and northwest. The adult female is about 2 ft. long, with an extent of wings of 4 ft. and a weight of about 3 lbs.; the male is smaller; both sexes

American Goshawk (*Astur atricapillus*).

are alike in plumage. In the adult the general color of the upper parts is dark ash-gray, the shafts and sometimes the edges of the feathers black; head above and neck behind black with a grayish tinge; a broad line of white over each eye; under parts grayish white,

sides and abdomen tinged with brown; blackish brown longitudinal streaks on the fore neck, and transverse blackish gray lines on the breast, sides, and belly; quills brown, ashy on their inner webs; tail with four or five broad brownish black bands, and narrowly tipped with white. The young birds are dark brown above, with light markings; the tail ashy; the under parts white, with yellowish red tinges, each feather with a longitudinal stripe ending in a brown ovate spot. This is one of the boldest and most rapid of the genus, and follows with untiring wing the flocks of wild pigeons and ducks; it seldom alights unless to devour its prey, and when thus engaged stands very erect. The nest is of large size, flat, and made of coarse materials; the eggs are of a bluish white color, sometimes with light brownish spots.—The European goshawk resembles the American, but the transverse bands on the under surface are much more regular. It equals the gerfalcon in size, but not in strength and courage; though an ignoble bird, and falling obliquely on its prey, it is used in falconry for the weaker and ground game, such as hares and rabbits, or birds of low flight like grouse and ducks.

**GOSHEN**, in Biblical geography, the district of Egypt in which Jacob and his family settled, and where his descendants remained till their deliverance by Moses. The locality is generally fixed in Lower Egypt, E. of the Pelusiac branch of the Nile.

**GOSHEN**, a town and village, one of the county seats of Orange co., New York, on the Erie railway, at the junction of two branches, 48 m. N. N. W. of New York; pop. of the town in 1870, 3,903; of the village, 2,205. It is celebrated for its excellent butter, which is made chiefly for the New York market. The village contains a female seminary, several classical schools, two national banks, and two weekly newspapers.

**GOSLAR**, a town of Hanover, Prussia, 26 m. S. E. of Hildesheim, on the Gose, at the base of the Rammelsberg; pop. in 1871, 8,923. Its most important public edifices are the town house, which was erected in the 15th century, the imperial palace, now in part a ruin, and the Gothic church, whose library contains a considerable number of Luther's manuscripts. In the vicinity are slate quarries, from which N. Germany is supplied with that material. The inhabitants are chiefly engaged in mining and quarrying. It was founded about 920, was the residence of several German emperors, and was a free imperial city till 1801.

**GOSNOLD**, Bartholomew, an English voyager, died in Virginia, Aug. 22, 1607. He joined Raleigh in his attempt to colonize Virginia, and after the failure of that enterprise was placed in command of an expedition fitted out for planting a settlement in New England. He sailed from Falmouth, March 26, 1602, with one small vessel and a company of 32 persons, 20 of whom were colonists. Instead of follow-

ing the usual route by the Canaries and West Indies, he steered directly across the Atlantic, and in seven weeks reached Massachusetts bay, first seeing land probably not far N. of Nahant. Thence he turned S., and landed on Cape Cod, to which he gave the name it still bears. Sailing around the promontory, and stopping at the island now known as No Man's Land, but which he called Martha's Vineyard, Gosnold anchored at the mouth of Buzzard's bay, and resolved to plant his colony on an island which he called Elizabeth (now known by its Indian name of Cuttyhunk). The adventurers here built and fortified a house, but the hostility of the Indians, scarcity of provisions, and disputes about a division of the profits, disheartened them, and the whole party returned to England, accomplishing the voyage in five weeks, and taking a cargo of sassafras root, cedar, furs, and other commodities. The result of the expedition was such as to encourage many others to follow the same short route across the ocean, and pursue the explorations which Gosnold had begun. Gosnold next turned his eyes toward Virginia, and succeeded in organizing a company for colonization in that region, the heads of which were Edward Wingfield, a merchant, Robert Hunt, a clergyman, and Capt. John Smith. A charter was granted them by James I., April 10, 1606, which was the first instrument of that nature under which the English were planted in America; and on Dec. 19, 1606, Gosnold set sail with three small vessels and an ill-assorted band of 105 adventurers. After a tedious voyage, a storm having driven them into Chesapeake bay (April 26, 1607), they sailed up James river, which they named after the king, disembarked about 50 m. above its mouth, and founded the settlement of Jamestown. Sickness and various disasters destroyed 50 of their number before autumn, among whom was Gosnold.

**GOSPEL** (Sax. *godspell*, corresponding to the Gr. *εὐαγγέλιον*, a joyful message), either the whole system of the doctrines of Christ, or one of the four histories of his life and teachings written by Matthew, Mark, Luke, and John. The extant spurious gospels, forming a part of the apocrypha of the New Testament, are the "History of Joseph the Carpenter," the "Gospel of the Infancy," the "Gospel of Thomas the Israelite," the "Protevangelion" of James, the "Gospel of the Nativity of Mary," and the "Gospel of Nicodemus, or Acts of Pilate." Many others, not extant, are mentioned by the church fathers. (See *APOCRYPHA*.)

**GOSPORT**, a seaport town of Hampshire, England, opposite Portsmouth, on the W. side of the entrance to the harbor of the latter; pop. in 1871, 7,366. It is situated on level ground and surrounded by fortifications, which form part of those of Portsmouth and Portsea. It contains two churches and four chapels for Protestants and one for Roman Catholics. The most conspicuous establishment is the royal Clarence victualling yard for supplying vessels.

**GOSSE, Edmund William.** See supplement.

**GOSSE, Philip Henry**, an English zoölogist, born in Worcester, April 6, 1810. While in Newfoundland in a mercantile capacity, 1827-'35, he occupied his leisure in collecting insects and making colored drawings of them. He removed to Lower Canada, where he pursued his studies of zoölogy, particularly entomology, for three years, and afterward travelled in the United States, making in Alabama numerous drawings of the *lepidoptera* of that region, and wrote "Letters from Alabama, chiefly relating to Natural History." After his return to England in 1839, he published the results of his observations under the title of the "Canadian Naturalist" (London, 1840). In 1844 he visited Jamaica to study its zoölogy, and on returning after 18 months published "The Birds of Jamaica," which was followed by an "Atlas of Illustrations" and "A Naturalist's Sojourn

in Jamaica." During the subsequent years he published an "Introduction to Zoölogy," and prepared many works for the society for the promotion of Christian knowledge. He then devoted himself especially to the microscopic study of the British *rotifera*, and took a prominent part in the formation of public and private collections of marine animals. In 1856 he was elected a member of the royal society. His remaining works include: "The Aquarium" (1854); "Manual of Marine Zoölogy" (1855); "Tenby, a Seaside Romance" (1856); "Life in its Lower, Intermediate, and Higher Forms" (1857); "Omphalos, an Attempt to Untie the Gordian Knot" (1857); "Evenings at the Microscope" (1859); "Actinologia Britannica, a History of the British Sea Anemones and Corals" (1860); "The Romance of Natural History" (1860-'62); "A Year at the Shore" (1865); and "Land and Sea" (1865).

**GOSSELIES**, a market town of Belgium, in the province of Hainaut, on the Brussels and Charleroi railway, 23 m. S. by E. of Brussels; pop. in 1866, 6,511. It has important manufactories of woollens, hats, steel ware, and leather, and near it are large coal mines. The battle fought near this place June 26, 1794, between the French and the Austrians, is known as the battle of Fleurus.

**GOTHA. I.** Formerly an independent duchy (Saxe-Gotha), but now politically united with Coburg under the name of Saxe-Coburg-Gotha; pop. of Gotha in 1871, 122,630. (See SAXE-COBURG-GOTHA.) **II.** The capital, and alter-

nately with Coburg the residence of the duke; pop. in 1871, 20,591. It is the principal station of the Thuringian railway, by which the distance to Halle is 83 m. and to Weimar 30 m. The palace of Friedenstein adjoins the town, and contains collections of fine arts and one of the richest collections of coins in Europe; also a library with upward of 200,000 volumes

The Ducal Palace, Gotha.

and more than 6,000 manuscripts, among which are 14 folio volumes of St. Bernard's correspondence and about 3,000 Arabic and Persian manuscripts. Gotha has a famous gymnasium, many excellent educational and charitable institutions, and an observatory established in 1859 by Hansen. It is one of the most prosperous trading and manufacturing places of Thuringia. It is the seat of a celebrated fire and life insurance company, and of the geographical establishment of Justus Perthes, the publisher of the *Almanach de Gotha*.

**GOTHAM**, a parish of Nottinghamshire, England, the Boëotian rusticity of whose inhabitants gained them the proverbial appellation of "the wise men of Gotham." The name Gotham was satirically applied by Washington Irving to the city of New York.

**GOTHENBURG**, or **Gottenburg** (Swed. *Göteborg*) **I.** A län or province of Sweden, in the S. W. part of the kingdom, bordering on the Catte-gat, the Skager Rack, and Norway; area, 1,890 sq. m.; pop. in 1873, 236,899. It forms a narrow strip of land between the mountains which separate it on the east from the province of Elfsborg and the rugged coast, which is indented by numerous bays and bordered by many small islands. The climate is severe; the soil is sterile, and there are few manufactures except in the capital city. **II.** The capital of the province, and the second commercial city of Sweden, at the head of a fiord on the Catte-gat at the mouth of the Götha river, 240 m. W. S. W. of Stockholm; pop. in 1873, 59,329.

It has a good harbor, with 17 ft. of water, enclosed by two long ridges of rock about  $1\frac{1}{2}$  m. apart. There is anchorage for vessels of large size, but only the smaller craft can come up to the shore. The city is intersected by navigable canals, and as it occupies marshy ground, the houses of the lower town are generally built on piles. The upper town stands on adjacent rocky heights. The houses are mostly of stone or stuccoed brick, with terraced roofs. The

principal public edifices are the cathedral, the Swedish church, the new exchange, the arsenal, the town hall, the theatre, and the East India house. The manufactures comprise cottons, woollens, sail cloth, tobacco, snuff, glass, paper, leather, refined sugar, and porter. Most of the merchants are Scotch and English. In 1872 the entries at the port were 2,161 vessels, of 598,487 tons; the clearances 1,800 vessels, of 548,545 tons. The city was founded by Gus-

Gothenburg.

tavus Adolphus in 1618, and was once well fortified. It has had frequent fires.

**GOTHIC LANGUAGE AND LITERATURE.** The Gothic language became extinct with that Germanic race by whom it was spoken. The existing Gothic manuscripts are written in characters related in form and order to the Greek alphabet, and, it is said, invented by Bishop Ulfilas. The order of the alphabet has been ascertained from the numerical values attached to the letters. It is not customary in modern books to make use of Ulfilas's characters. The original form, order, and numerical value of the Gothic alphabet, and the way in which it is usually transcribed, are as follows:

FORM.	NUM.	VALUE.	TRANSC.	FORM.	NUM.	VALUE.	TRANSC.
Ἀ	1	a		Ḡ	60	j	
Β	2	b		Ḣ	70	u	
Γ	3	g		Π	80	p	
Δ	4	d		Υ	90	—	
Ε	5	ê		Ḳ	100	r	
Ṽ	6	kv (q)		Ṣ	200	s	
Ζ	7	z		Ṭ	300	t	
Η	8	h		Υ	400	v (w)	
Ϸ	9	th (þ)		Ḟ	500	f	
Ἰ	10	i		Χ	600	z (ch)	
Ḳ	20	k		Θ	700	hv	
Λ	30	l		Ϸ	800	ð	
Ḣ	40	m		Ṭ	900	—	
Ṽ	50	n					

The transcription of several letters is not uniform. Some write, instead of *kv, qu*; for *v*, the German *w*; and instead of the aspirated *hv*, a simple *v* or *w*. Diacritical points are put over *i* at the beginning of a word, or after another vowel with which it does not form a diphthong. Numbers are distinguished in the manuscripts by a dash over the letters, or by being enclosed by two dots. For punctuation a colon is sometimes used, and it serves to divide a discourse into parts generally larger than a proposition. No Gothic manuscript, however, separates the words of a sentence, or indicates whether a vowel is long or short. The Gothic verb distinguishes two voices, active and middle; two tenses, present and past; three moods, indicative, optative, and imperative; three numbers, singular, dual, and plural; an infinitive; and a present and a past participle. According to the formation of the tenses, there are three classes of verbs: the first forms the past by reduplicating the verbal root; the second distinguishes the tenses by a change of vowel; the third has a special form only for the present tense, forming the past by means of formative endings. Grimm designates the first two classes as strong, and the third as feeble. Examples: 1st class, *blanda*, blend, *baibland*, blended; *têka*, touch, *taitók*, touched; 2d class, *binda*, band, *bund*, bind, bound, bound; *giba*, *gab*, *gêb*, give, gave, given; 3d class, *haba*, *habaida*, *habaiþs*, have, had, had; *sôkja*, *sôkida*, *sôkiþs*, seek, sought, sought. The past tense is formed in the last class by adding *da*, reduplicated *dad*, the auxiliary *do*, did. The verb to be is conjugated as follows: Pres. ind. singular, *im*, *is*, *ist*;

dual, *siu* or *siju*, *siuts* or *sijuts*; plural, *sium*, *siup*, *sind*. Past ind. singular, *vas*, *vast*, *vas*; dual, *vésu*, *vésuts*; plural, *vésun*, *vésup*, *vésun*, &c. Nouns have three genders and two numbers. They have inflections for the nominative, genitive, dative, and accusative cases, and a few have also a vocative case, but only in the singular. The stems end either in the vowels *a*, *i*, *u*, or in the consonants *n*, *r*, *nd*, and these terminations determine the modes of the declensions. The thematic vowel of the declension in *a* is distinctly preserved only in the dative singular and the dative and accusative plural, and is lengthened into *ô* in the feminines. The *i* of the next declension takes gradation, and an *a* is introduced before it. The declension in *u* retains the vowel of its theme quite persistently, even before the case sign *s* of the nominative masculine and feminine, as well as in the nominative neuter, where the other declensions drop it. The *n* of the theme disappears in the nominative and vocative of the singular. The vowel of the primitive suffix *dar*, *par*, or *tar* (as in *fadar*, father, *brôpar*, brother, *dahtar*, daughter, and *svistar*, sister), is dropped where a case sign is added; as gen. *brôprs*, dat. *brôpr*. The themes in *nd* comprise present participles declined as substantives. Adjectives are inflected differently, adopting in about half of the cases the demonstrative pronoun *ja*, and assimilating with it; as *hardus*, hard, *hardjis*, *hardjamma*, &c. The comparative degree is rendered by means of the suffixes *is* and *ôs*, which retain their form at the end of adverbs, but are lengthened into *izan* and *ôzan* at the end of adjectives. The superlative is formed by adding *ta* or *tan* to the *is* or *ôs* of the comparative; as *frôda*, clever, comp. masc. and neut. *frôdôzan*, fem. *frôdôzein*, sup. masc. *frôdista*, fem. *frôdisto*, &c. The personal pronouns are: *ik*, I; *pu*, thou; *is*, he; *si*, she; *ita*, it; *weis*, we; *vit*, we two; *jus*, you; *eis*, they masc.; *ijôs*, they fem; *ija*, they neut. Prepositions govern the genitive, dative, or accusative, and precede the words they govern. Only three interjections have been found: *ô*, oh; *sai*, behold; *vai*, woe! The pronouns *sa*, *sô*, *pata*, he who, she who, that which, are used as definite articles. There is no indefinite article.—The literary documents in which the Gothic language has been preserved consist of a few manuscripts. The *Argenteus Codex*, now in the library of the university of Upsal, written in silver and partly gold letters, is a purple parchment, supposed to date from about the beginning of the 6th century, at the time of the rule of the Ostrogoths in Italy. (See ARGENTEUS CODEX.) It comprised originally 330 sheets, with Ulfilas's translation of the gospels of Matthew, John, Luke, and Mark, in this order; but only 177 sheets have been preserved. (See ULFILAS.) The *Codex Carolinus* is a rescript, like all codices except the preceding, and is owned by the Wolfenbüttel library. It was discovered in 1756, and is also supposed to be of Italian origin. It con-

tains about 42 verses of the 11th to the 15th chapter of the epistle to the Romans. The five *Codices Ambrosiani* form part of the Ambrosian library in Milan, and contain fragments of the Pauline epistles, of the gospels of Matthew and John, of the books of Ezra and Nehemiah, and a calendar. They were discovered in 1817 at the convent of Bobbio in Italy. There is a parchment manuscript in Vienna dating from the 9th century, which contains a Runic and several Gothic alphabets, with a few words and numerical notations. Naples and Arezzo have each a Gothic certificate of sale written on papyrus. Another manuscript was discovered in 1866 by Franz Pfeiffer. It has received the appellation of *Codex Turinensis*, and consists of four sheets which had been used as the cover of a book or manuscript, and which contain fragments of the epistles to the Colossians and Galatians. Von der Gabelentz published an account of it in the *Germania* of 1867, and pronounced them illegible. In the following year, however, a translation by Massmann appeared in the same periodical. A complete edition of the literary monuments of the Gothic language has been published in Leipsic by Von der Gabelentz and Löbe (1836-'42), and another in Stuttgart by Massmann (1856-'7). Andreas Uppström has caused an exact reprint to be made of every line of Gothic manuscript extant. He published in this manner in 1854 the *Codex Argenteus*, and in 1861 the *Codex Carolinus* and some of the Ambrosian fragments. He died in 1865, and his son published in 1868, from his posthumous papers, the remaining documents. Since the texts could thus be critically studied, the Gothic grammars and vocabularies have been considerably changed. The latest researches are embodied in the 5th edition of Stamm's *Ulfilas, oder die uns erhaltenen Denkmäler der gothischen Sprache: Text, Wörterbuch und Grammatik*, which has been revised by Moritz Heine (Paderborn, 1872).

**GOTHLAND.** See GOTTLAND.

**GOTHS** (Lat. *Gothones*, *Guttones*, &c.), an extinct Germanic race, first mentioned as dwelling on the coasts of the Baltic during the 4th century B. C., and disappearing from history in the 8th century A. D. Their origin has not been ascertained. Pytheas of Massilia is the first who makes mention of them; he found them at the side of the Teutons in the southern portion of the Baltic region. Pliny, in the 1st century A. D., and Ptolemy, in the 2d, place them in the same territory. The name of Getæ given to them by later historians does not properly belong to the Gothic race, though Grimm's hypothesis connects the Getæ with the Goths. Cassiodorus, the principal minister of Theodoric the Great, wrote a history of the Goths, which chronicles their migrations and wanderings from regions beyond the Baltic. Procopius speaks of Goths, Vandals, and Gepidæ as one people in all respects, and describes them as of fair complexion, with reddish yellow hair and

tall manly forms. Modern authorities consider the Vandals, Heruli, Rugii, Gepidæ, Alani, Suevi, Longobards, Burgundians, and Franks as the principal families of the Gothic race.—In the latter half of the 2d century A. D. the Goths appear on the N. shores of the Black sea. In the 3d century they were in possession of the region N. of the lower Danube. They invaded the Roman territory in 237, plundered Thrace, and defeated the emperor Decius in 251. A few years later they were defeated by Æmilianus; but in 262 they ravaged Greece, and in 269 invaded the Roman empire again. The emperor Claudius defeated them in that year at Naissus. In 272 they obtained possession of Dacia. They invaded Mœsia in 332, but were repulsed. In 366 they assisted in the revolt of Procopius; but Valens defeated and drove them beyond the Danube. Meanwhile they had become divided into Ostrogoths and Visigoths, or Eastern and Western Goths. The former inhabited southern Russia between the Dniester and the Don; the latter the territory from the lower Danube to the Carpathian mountains, and from Hungary to Bessarabia. Ermanric, who ruled over both bodies, came in collision with the Huns in 375, and was defeated by them. The Goths put themselves thereupon under the protection of Valens, who assigned them a territory in Thrace; but reaching the provinces of Mœsia (Bulgaria and Servia), they took possession of the country, defeated Valens in a battle near Adrianople in 378, and ravaged Achaia and Pannonia. The Visigoths submitted to the Romans in 382; but the Ostrogoths continued their ravages several years longer, and finally settled in Thrace and Phrygia. Several Gothic tribes had already embraced the Christian faith, and about the year 360 Ulilas, bishop of the tribes who dwelt in Mœsia and Thrace, had translated the New Testament into the Gothic language. Upon the death of Theodosius, the barbarian nations took advantage of the dissensions of his successors to overrun the divided empire. The Huns poured in from one direction, while an army of Goths under Alaric invaded the region between the Adriatic and Constantinople, and subsequently marched into Italy and sacked Rome. (See ALARIC.) The Goths gradually intermingled in blood with the inhabitants of Italy. The Huns under Attila, 500,000 barbarians of many tribes, now threatened Italy and entered Gaul (A. D. 451). They were encountered by Romans and Goths, combined under command of Aëtius, and suffered a terrible defeat. Theodoric, king of the Visigoths, was among the slain on the side of the Romans. Meanwhile Spain and southern France came under Gothic dominion; and Odoacer, a prince of the Heruli, penetrating into Italy, dethroned Augustulus, the last of the West-Roman emperors, and assumed the title of king of Italy (A. D. 476). Zeno was emperor of the East, and, becoming embroiled with the Ostrogoths under Theodoric, consented to an invasion of Italy by this prince.

Theodoric accordingly crossed the Alps, defeated Odoacer, compelled from him, at Ravenna, the surrender of all Italy, and put him to death (493). Italy had begun to prosper under Odoacer, and the impulse was increased by the new king, who reigned 33 years. Profiting by the Gothic disorders consequent upon the death of Theodoric in 526, Justinian sent Belisarius to Italy. He took Rome, and, gaining the admiration of the Goths, was invited to be their king. This he refused, but held the Goths in subjection for his master. Totila, a noble Goth, rebelled, and mastered southern Italy. He was about to destroy Rome, but, yielding to the remonstrance of Belisarius that it would add more to his honor to spare it, contented himself with dispersing the inhabitants (546), and repopling it before the arrival of a fresh army from Constantinople under Narses. Totila fell in battle (552), and his successor Teias suffered the same fate (553). Italy was reconquered, and the Gothic monarchy founded by Theodoric the Great was extinguished. In Spain and southern France the Visigoths maintained a splendid monarchy till 711, when Roderic was killed in battle against the Moors, who, crossing from Africa, subjugated the kingdom.—The Goths became a cultivated and enlightened people. Grotius gives them high commendation for morality, integrity, love of justice, and good faith. There never had been a better administration in Italy than that of Theodoric. He was an Arian, but the Catholics were not only unmolested by him, but themselves generally acknowledged that at no other period did their church enjoy greater prosperity. The Gothic princes and tribes were generally tolerant of the faith of others. They were also distinguished in some degree as friends of fine arts, science, and learning. Theodoric maintained overseers of works of art, whose duties were to guard the statues and to watch over the preservation of public buildings. These were kept in repair, and others were erected. The old Gothic style of architecture, comprising what are called transition styles with the rounded arch, Byzantine, Lombard, Norman, &c., was thus originated; a simple massive character of art, which must not be confounded with modern Gothic, which dates even later than the Lombards in Italy.—The laws of the Visigoths were digested into a regular code 50 years before the Pandects of Justinian, who possibly borrowed the idea of a code from the Visigothic princes. Theodoric and the Goths in Italy preserved and improved the Roman laws. (See CIVIL LAW, vol. iv., p. 623.) Their form of government was absolute monarchy of a mixed elective and hereditary nature; and it has been said of most of the Gothic rulers in Italy, that they made good the promise of Theodoric, who on ascending the throne said that he would strive so to rule the empire that the “only regret of the people should be that the Goths had not come at an earlier period.”

**GÖTTINGEN**, a city of Prussia, in the province and 57 m. S. by E. of the city of Hanover; pop. in 1871, 15,841. It is the seat of a university (*Georgia Augusta*), which was founded in 1734 by King George II. of England and elector of Hanover, and inaugurated Sept. 17, 1737. Through the eminence of several of its professors, among whom were Gesner, Heyne, Michaelis, and the two Eichhorns, it became toward the end of the century the most famous university in Europe. Its fortunes were not materially changed until the foundation of the university of Berlin (1810), which proved a formidable rival. The students, however, still numbered 3,000 in 1825, but the political disturbances of 1831 caused a great diminution in the attendance, which in 1834 was reduced to about 900. Yet the university could still boast of a brilliant array of names on its staff, among whom were Blumenbach, Ewald, Mitscherlich, Müller, Gervinus, Heeren, and the brothers Grimm. The new university building was inaugurated on the day of its 100th anniversary in 1837, but before the end of the year the government expelled seven of the ablest professors, who had protested against the abrogation of the Hanoverian constitution by King Ernest. Two of the expelled professors, Ewald and Weber, resumed their functions in 1848, but Göttingen has never recovered from the shock which it had received, although it numbered in 1873 101 professors and 925 students. The university library comprises 360,000 volumes and 5,000 manuscripts; it surpasses almost all other German libraries in its copious collections of modern works, and is one of the best arranged libraries in Europe. The academy of sciences comprises sections for mathematics, natural sciences, and history. The *Gelehrte Anzeigen*, the oldest learned periodical in Germany, is published under its auspices. The museum of natural history contains a collection bequeathed to it by Blumenbach, including human skulls of natives of all quarters of the globe, a large collection of coins, and some few works of art. Connected with the university are seminaries for theology, philology, mathematics, and natural sciences; hospitals, clinics, and an anatomical theatre; a botanical and economical garden, a school for veterinary surgeons, a chemical laboratory, a fine physiological institution, an observatory, and an agricultural school. Prominent among the other educational establishments is the industrial school of Wagemann. There are five Lutheran churches, including the university church, a Reformed and a Roman Catholic church, and a synagogue. The charitable institutions are numerous. The manufactures consist of cloth, woolen stuff, surgical instruments, soap, leather, turnery, gold and silver wares, &c.

**GOTTLAND**, or *Gothland*, an island in the Baltic, belonging to Sweden, between lat. 56° 55' and 57° 53' N.; length about 80 m., greatest breadth 33 m.; area, about 1,200 sq. m.; pop.

in 1873, 54,239. The island is generally level, and but here and there slightly hilly. The climate is temperate, the mulberry and grape ripening in the open air. The people are chiefly employed in rearing cattle and fishing off the coast. The island possesses several good harbors. The chief towns are Wisby and Slite, the latter protected by forts. A submarine telegraph connects the island with the mainland of Sweden.

**GOTTSCHALK**, *Louis Moreau*, an American pianist and composer, born in New Orleans, May 8, 1829, died in Rio de Janeiro, Dec. 18, 1869. His father was an Englishman of German-Jewish descent, and his mother was of French extraction. Louis was their eldest child, and gave evidences of a remarkable musical organization at three years of age. At six he took lessons on the piano and violin, and at twelve was sent to Paris, receiving there instruction from Hallé and Camille Stamaty on the piano and from Maleden in harmony. He also formed the friendship of Hector Berlioz, from whom he received valuable advice. His first appearance as a pianist was on the continent, and it was not until Feb. 11, 1853, that he was heard in the United States, in concerts in New York and elsewhere. The class of music that he played and his skill made for him at once a widely extended reputation, and during his whole career he commanded the admiration of large and enthusiastic audiences. Although a composer, his published works exceeding 50 in number, he was preëminently a pianist. His compositions grew out of his love for the instrument, and were almost all written with a view to its capabilities. He seemed to have no grasp of musical effects except such as were producible upon the piano. The pieces on which his reputation principally rests were illustrative of tropical life, such as *Le bananier*, *La savane*, *Ricordati*, *La marche de nuit*, *O ma charmante*, *Le mancenillier*, *Réponds moi*, *Ojos criollos*, and many Cuban dances. His arrangements of the compositions of others are few in number and of no special merit; nor had he any exceptional skill as an interpreter of the works of other composers. He constantly played his own compositions, and with a sensuous charm that no other pianist could approach. His touch was one of extreme delicacy as well as force, and there were no difficulties of the instrument that he had not mastered. The piano sang under his hand with wonderful expression. He died suddenly while at the height of his reputation.

**GOTTSCHALL**, *Rudolph*, a German poet and dramatist, born in Breslau, Sept. 30, 1823. He studied law at Königsberg, where he published anonymously in 1842-'3 *Lieder der Gegenwart* and *Censurflüchtlinge*. He was afterward expelled from the university of Breslau on account of a political demonstration made in his favor. After some time he was allowed to resume his studies in that city, but could not obtain a license as a professor, though he re-

ceived a diploma as doctor of philosophy at Königsberg, where he became a dramatist. Subsequently he resided at Hamburg, Breslau, and Posen, and from 1864 at Leipsic as editor of *Unsere Zeit*, of *Blätter für literarische Unterhaltungen*, and of *Der neue Plutarch* (1874 *et seq.*). His poetical works include *Gedichte* (1849), *Die Göttin* (1853), *Carlo Zeno* (1854), *Neue Gedichte* (1858), *Kriegslieder* (1871), and *Janus: Friedens- und Kriegsgedichte* (1873). The most renowned of his plays are the comedy *Pitt und Fox*, the drama *Mazeppa*, and the tragedies *Katharina Howard* and *Herzog Bernhard von Weimar*. Among his prose writings are *Die deutsche Nationalliteratur im 19. Jahrhundert* (3 vols., 1853-'72), *Poetik* (1858), and *Porträts und Studien* (4 vols., 1870-'71).

**GOTTSCHED, Johann Christoph**, a German author, born at Judithenkirch, near Königsberg, Feb. 2, 1700, died in Leipsic, Dec. 12, 1766. He was educated at Königsberg, studied theology, but abandoned it for philosophy and belles-lettres, and was for 32 years professor of logic and metaphysics at Leipsic. He became president of the literary society of Leipsic in 1726, held for a time a sort of literary dictatorship in Germany, placing purity of language and clearness and elegance of style above all other literary merits, while his opponents of the Zürich school, Bodmer and others, contended for originality and genius. He was an indefatigable author, and left tragedies, translations, philosophical treatises, and various controversial and critical works. His chief merit was in contributing to make the German language the sole medium of instruction, by publishing popular manuals and abridgments of scientific and philosophical works in the vernacular tongue.

**GOUDA**, a town of the Netherlands, in the province of South Holland, on both banks of the Gouw at its junction with the Neder Yssel, 11 m. N. E. of Rotterdam; pop. in 1868, 15,776. It is entered by five gates, and has canals through the centre of all its streets. It has five churches, that of St. John being very magnificent. The principal manufactures are tobacco pipes, cotton fabrics, parchment, leather, and white lead.

**GOUCH, Hugh**, viscount, a British general, born at Woodstown, Ireland, Nov. 3, 1779, died March 2, 1869. He entered the army in 1794, and, after serving against the Dutch at the Cape of Good Hope and in the West Indies, in 1809 joined the British forces in Spain, distinguishing himself at Talavera, Barrosa, Vitoria, Nivelle, &c. During the war in China (1841) he was commander-in-chief of the land forces, and for his services was made a baronet. Having been transferred to India with the supreme command, in December, 1843, he gained the battle of Maharajpore against the Mahrattas of Gwalior. Upon the breaking out of the first Sikh war in 1845, he defeated the enemy at Moodkee, Dec. 18, and again at Ferozeshah on the 22d. He finished

the campaign, Feb. 10, 1846, by taking the entrenched camp of the Sikhs at Sobraon, though with terrible loss to his own troops. For these victories he was raised to the peerage as Baron Gough. His services in the second Sikh war (1848-'9) were characterized by bravery rather than generalship. At Mamnuggar an indecisive battle was fought. Another at Chillianwallah (Jan. 13, 1849) came near being a defeat; but after a severe struggle the British remained masters of the field, though with the loss of nearly 2,500 men. On Feb. 21 Gough completely routed the Sikhs at the town of Guzerat. News of the dearly bought victory of Chillianwallah having reached England, Gough was superseded in the command of the Indian army by Sir Charles Napier. The veteran, however, was raised to the additional rank of viscount in acknowledgment of his bravery and long service, was thanked by parliament, and a pension of £2,000 was settled upon himself and his two next successors. He was made field marshal in 1862, and at his death was commander of the forces.

**GOUGH, John B.**, an American orator, born at Sandgate, England, Aug. 22, 1817. He came to America in 1829, and soon after became a bookbinder's apprentice in New York. He became intemperate, and was accustomed to sing and recite in grog shops, where his powers of mimicry and action made him a favorite. He fell into great poverty, but about 1840 took the temperance pledge, and soon began to lecture on temperance, both in America and England. In time he added other subjects, and became a very popular orator. In November, 1873, he recited one of his orations in New York, announcing that this would probably be his last public appearance in that city. He has published his autobiography (1846), and a volume of orations (1854). He resides near Worcester, Mass.

**GOUGH, Richard**, an English antiquary, born in London, Oct. 21, 1735, died Feb. 20, 1809. He was a fellow of the royal society, and for many years director of the society of antiquaries, of which he wrote a history, and to whose *Archæologia* he was a frequent contributor. Among his works are enumerated an edition of Camden's *Britannia*, the valuable additions to which were the fruit of many excursions through England, Scotland, and Wales; "Anecdotes of British Topography" (4to, 1768; enlarged, 2 vols. 4to, 1780); and "Sepulchral Monuments of Great Britain" (3 or 5 vols. fol., 1786-'96).

**GOUJET, Claude Pierre**, a French author, born in Paris, Oct. 19, 1697, died there, Feb. 1, 1767. He was educated at a college of Jesuits, entered the order of Oratorians, and proved a zealous Jansenist. His labors as historian, compiler, and critic injured his health during his later years; he lost his sight, and was obliged to sell his library. Of his many works the following are the most important: *Bibliothèque des écrivains ecclésiastiques* (3 vols.,

1736); *Dissertations sur l'état des sciences en France depuis la mort de Charlemagne jusqu'à celle du roi Robert* (1737); *Histoire du pontificat de Paul V.*; *Bibliothèque française, ou Histoire littéraire de la France* (18 vols. 12mo., 1740-'59); *Mémoire historique et littéraire sur le collège royal de France* (4to, 1758); and *Mémoires historiques et littéraires* (1767). He edited Richelet's *Dictionnaire*, and Morel's *Dictionnaire historique*.

**GOUJON, Jean**, a French sculptor, born in Paris about 1515, said to have been killed there on St. Bartholomew's day, Aug. 24, 1572. Little is known of his life until 1541, when he was employed at Paris in producing the beautiful sculptures of the rood loft of St. Germain-l'Auxerrois, and at Rouen in the cathedral and in the church of St. Maclou. In 1548 Henry II. employed him in decorating the château of Anet, which he was building for his mistress, Diana of Poitiers. There he produced the celebrated group, now belonging to the Louvre, of Diana and the stag. Another huntress Diana by him is in the château of Malmaison. In 1550 the *fontaine des innocents* was commenced in the rue St. Denis; it was transported in 1788 to the square which it now adorns. He was also employed as an architect on the old Louvre. Several of his best works are still extant. See *Œuvres de Jean Goujon*, with 90 outline plates by Reveil (Paris, 1844).

**GOULBURN**, a city of New South Wales, Australia, in Argyle co., near the junction of the Mulwarree ponds and Wollondilly river, on the Great Southern railway, 120 m. S. W. of Sydney; pop. about 3,500. It is the seat of an Anglican and a Roman Catholic bishop. Prominent among the public buildings are several churches, the hospital, the mechanics' institute, the court house, and the jail. The progress of the town has thus far been chiefly due to agriculture; but in its vicinity are found gold, copper, and other metals, and marble. Goulburn was made a city in 1865. In 1872 it had three newspapers.

**GOULBURN, Edward Meyrich**, an English clergyman, born in 1818. He was educated at Eton, and at Balliol college, Oxford, became fellow of Merton college in 1841, and for a number of years was a tutor in the university, being at the same time incumbent of Holywell, Oxford. In 1850 he was elected head master of Rugby school, and in 1858 became minister of Quebec chapel and prebendary of St. Paul's, London. He was also appointed one of the chaplains in ordinary to the queen and incumbent of St. John's, Paddington, and in 1866 was made dean of Norwich. Dean Goulburn is a voluminous and popular writer. Among his chief works are: "The Doctrine of the Resurrection of the Body" (Bampton lectures, 1850); "Principles of the Cathedral System Vindicated;" "Thoughts on Personal Religion," with a sequel on the "Pursuit of Holiness;" "Sermons in Norwich" (1870); and "The Holy Catholic Church" (1873).

**GOULD, Augustus Addison**, an American naturalist, born in New Ipswich, N. H., April 23, 1805, died in Boston, Sept. 15, 1866. His father's family name was Duren, which was changed to that of Gould. He graduated at Harvard college in 1825, took his medical degree in 1830, and commenced practice in Boston. During his college life he devoted his spare moments to the study of natural history; in the early part of his professional career he lectured frequently on scientific subjects, and for two years gave instruction in botany and zoölogy at Harvard college. In 1855 he delivered the annual discourse before the Massachusetts medical society, and in 1856 received the appointment of visiting physician to the Massachusetts general hospital. He was an accomplished naturalist, and in the department of conchology stood preëminent both at home and abroad. His principal published works are: a translation of Lamarek's "Genera of Shells" (1833); "System of Natural History" (1833); "The Invertebrate Animals of Massachusetts" (1841); "Principles of Zoölogy," with Prof. Agassiz (1848); "Mollusca and Shells of the United States Exploring Expedition under Capt. Wilkes" (4to, 1852, with an atlas of plates); the completion of Dr. A. Binney's "Land Mollusks of the United States" (3 vols. 4to, 1851-'5); "The Mollusca of the North Pacific Expedition under Cpts. Ringgold and Rogers" (1860); and "Otia Conchologica" (1863). He was also a frequent contributor to scientific and literary periodicals.

**GOULD, Benjamin Apthorp**, an American astronomer, born in Boston, Sept. 27, 1824. After graduating at Harvard college (1844), he went to Göttingen, where he pursued his mathematical and astronomical studies under Gauss, and took his degree in 1848. He was for some time an assistant in the observatory at Altona with Schumacher and Petersen. After visiting many of the chief observatories of Europe and spending some time at each, he returned to America, and was employed in the United States coast survey, having charge of the longitude determinations, the telegraphic methods of which he very greatly improved. In 1866 he made the first determinations of transatlantic longitude by telegraph cable. In 1866 he was appointed director of the Dudley observatory at Albany, and superintended its building and arrangement in 1857-'8. His occupancy of this post ended in January, 1859, owing to a disagreement with the trustees of the institution, which led to a prolonged and painful conflict, carried on through pamphlets and the public press. A committee of scientific men subsequently justified the action of Prof. Gould in the matters leading to this misunderstanding. In 1868 he was appointed to organize and direct the national observatory of the Argentine Republic at Cordova. After ordering the instruments in Europe and erecting the building at Cordova, he began work there with four assistants in 1870. Since that time he has

completed a set of maps of the stars visible with the naked eye from his observatory, with their positions and magnitudes, and afterward undertook a series of zone observations of southern stars. Up to April 15, 1874, the great number of 83,000 stars had been observed. Prof. Gould's principal works are: "Report on the Discovery of the Planet Neptune" (Smithsonian Institution, Washington, 1850); "Investigation of the Orbit of Comet V." (Washington, 1847); "Discussions of Observations made by the United States Astronomical Expedition to Chili, to determine the Solar Parallax" (Washington, 1856); "Discussion on the Statistics of the United States Sanitary Commission;" and the charts of stars already named, with others of scarcely less importance. In 1849 he founded at Cambridge, Mass., the "Astronomical Journal," the expenses of which were long borne by himself and a few friends. He continued to conduct it until its suspension in 1861.

**GOULD, Hannah Flagg**, an American poetess, born at Lancaster, Mass., in 1789, died at Newburyport, Sept. 5, 1865. She was a frequent contributor to periodical literature, and published a volume of poems in 1832, a second in 1836, and a third in 1841. Her other books are: "Gathered Leaves," a collection of prose sketches (1846); "The Diosma," containing original and selected poems (1850); "The Youth's Coronal" (1851); "The Mother's Dream, and other Poems" (1853); and "Hymns and Poems for Children" (1854).

**GOULD, John**, an English naturalist, born in Lyme, Dorsetshire, Sept. 14, 1804. Between the ages of 14 and 20 he resided at the royal gardens at Windsor, studying the habits of birds and collecting specimens. He was afterward engaged to prepare specimens for the museum of the London zoölogical society, and published "A Century of Birds from the Himalayan Mountains," with illustrations by his wife (fol., London, 1832). He next published "The Birds of Europe" (1832-'7). In 1838 he went to Australia, where he resided two years, collecting materials for his "Birds of Australia," also illustrated by his wife (7 vols. fol., 1842-'8), and for the "Mammals of Australia" (1845-'59). His "Monograph of the Trochilidae" (fol., 1850) was suggested by his unrivalled collection of humming birds, of which he had procured 2,000 specimens, illustrating 320 species. Among his remaining works are: "Monograph of the Ramphastidae" (fol., 1833-'5); "Icones Avium" (1837-'8); "Monograph of the Trogonidae" (1835-'8); "Monograph of the Macropodidae, or Family of Kangaroos" (1841-'2); "Monograph of the Odontophorinae, or Partridges of America" (1844-'50); a supplement to the "Birds of Australia," containing species recently discovered; and a "Handbook to the Birds of Australia," giving all the information on the subject to the close of 1865. In 1873 he was preparing works on Asiatic and on British birds.

**GOUNOD, Charles François**, a French composer, born in Paris, June 17, 1818. He studied counterpoint at the Paris conservatory under Halévy, receiving also instructions in composition from Lesueur and Paër. In 1837 he received the second prize of the institute, and in 1839 he obtained the first premium for his cantata *Fernand*. In consequence of this success he became privileged to pursue his training at Rome at the government expense, and there devoted himself to ecclesiastical music. In 1843 he visited Vienna, where he procured the performance, in the church of St. Paul, of a mass for voices only, in the style of Palestrina. Returning to Paris, he was appointed musical director at the church of the Missions Étrangères. Here he adopted the monastic garb, and remained in obscurity till 1851. On April 16, 1851, he produced unsuccessfully his first opera, entitled *Sappho*. In 1852 some choruses, written for M. Ponsard's classical tragedy *Ulysse*, were performed at the Théâtre Français. In October, 1854, *La nonne sanglante*, a grand opera, was performed unsuccessfully, as was in 1858 an attempt at comic opera, consisting of a musical setting of Molière's *Médecin malgré lui*. On March 19, 1859, was produced at the Théâtre Lyrique the work on which Gounod's reputation chiefly rests, *Faust*. This was succeeded by *Philémon et Baucis*, a three-act opera; *La reine de Saba*, a grand opera; *Mirella*, an Italian version of the French *Mireille*; and *Romeo e Giulietta*. In addition to these works, he has composed masses, psalms, and motets, for single and double chorus. Among the most praiseworthy of his compositions of this class are his "St. Cecilia Mass" and a setting of the psalm "By the Waters of Babylon." Of late years he has lived principally in London.

**GOUR, Gaur, or Lucknouti**, a ruined city of Bengal, British India, 179 m. N. of Calcutta. Its remains are spread over a range of low hills which extend along the E. bank of the Bhagruttee, and cover a space 7 m. long (15 m. including suburban villages) by 2 or 3 m. broad. Many of the buildings have been demolished for the sake of the bricks of which they were constructed, but several grand edifices are still standing. Of these the most remarkable are a mosque, built of brick, and lined with a kind of black porphyry, a curious building faced with bricks of various colors, an obelisk 100 ft. high, numerous reservoirs, and two lofty gates of the citadel. Several villages have grown up on part of the site, and the rest is mainly covered with forests or is under cultivation.—The earliest record of Gour dates from 648, when it was governed by independent chieftains. At the beginning of the 13th century it was taken by an officer of the viceroy of Delhi under Shahal ud-Din, monarch of Ghore in Afghanistan; and in 1212 it became the capital of Bengal, an eminence which it retained, except during an interval of about 50 years previous to 1409, until the British

gained possession of the district in the 18th century. Its decline, however, began about 1574, when Monaim Khan, commander of Akbar's troops, captured it and made it the seat of an independent power, but in a few months fell a victim, with nearly all his troops, to the deadly climate. No cause has since contributed so much to its decay as the diversion of the Ganges from its former to its present channel, 4 or 5 m. distant, in the 17th century.

**GOURD** (Fr. *gourde*, a swelling), a name applied in Europe to plants of the order *cucurbitaceæ* in general, but restricted in the United States to the *lagenaria*, the hard shell of which is put to various domestic uses. To the gourd family belong the pumpkin, squash, watermelon, cucumber, muskmelon, and several others cultivated for ornament or known as weeds. The members of the family are succulent tendrill-bearing herbs with a watery juice; alternate and palmately ribbed, lobed, or angled leaves, and monœcious, sometimes diceious

Common Gourd (*Lagenaria vulgaris*).

flowers; the calyx coherent with the ovary (flower superior); corolla mostly monopetalous; the stamens are usually three and singularly contorted and united; the fruit generally fleshy, but sometimes with a hard shell when ripe. The common gourd, bottle or calabash gourd, *lagenaria vulgaris*, is a native of Asia and Africa; it climbs to a great distance, and has clammy, unpleasantly scented leaves. The sterile flowers are on long stalks, white with greenish veins; the fertile on short stalks, and producing a fruit that varies much in shape. The commonest form is shaped like a water bottle with a large base and a swollen handle; the rind of this when ripe is very hard and woody. By making an opening at the place where the stem joins the fruit and removing the contents, it makes, after soaking to remove the bitterness, an excellent water bottle. With an opening in the side it is a convenient dipper; and when sawed in two across the

larger part, the lower portion forms a dish, while the upper serves as a funnel. A variety is known at the west as sugar-trough gourd, the large flattened-spherical shell of which will hold several gallons. Hercules's club or California gourd produces a fruit sometimes 5 or 6 ft. long. Under the name of ornamental or fancy gourds several, mostly species of *cucurbita*, are grown for their small, handsomely marked, and variously shaped fruit. (See PUMPKIN, and SQUASH.)

**GOURGAUD, Gaspard**, baron, a French general, born in Versailles, Sept. 14, 1783, died July 26, 1852. He studied at the polytechnic school, and at that of Châlons, entered the army in 1802, and fought in the campaigns of Germany (1805-'6), of Poland (1807), of Spain (1808), and again in Germany (1809). Sent to Dantzic in 1811 to examine the strength of its fortifications, his reports gained the favor of Napoleon, whom he accompanied to Russia in 1812. He was wounded at Smolensk; at Moscow he prevented an explosion of 5,000 cwt. of gunpowder stored in the Kremlin, and was rewarded with the title of baron. On the retreat he proved his bravery at the passage of the Beresina. He was first *officier d'ordonnance* to Napoleon during the campaign in Saxony in 1813, where after the battle of Leipsic he saved the corps of Oudinot by delaying the command of Napoleon to destroy the bridge of Freiberg. After the battle of Brienne in the campaign of 1814, he saved Napoleon at Mézières from a troop of Cossacks, one of whom was already aiming his lance at the emperor. After the fall of Napoleon he was well treated by the Bourbons, on whose flight he joined the emperor (1815). Made general after the battle of Fleurus, he was among the last on the battle field of Waterloo, followed Napoleon to Malmaison and Rochefort, and carried his letter to the prince regent of England. Chosen one of the three who were allowed to follow the emperor in his exile, he lived three years at St. Helena, but left the island in consequence of illness and misunderstandings, went to England, and tried in vain to interest the congress of Aix-la-Chapelle and Maria Louisa in favor of the emperor. In 1821 he was allowed to return to France, where a legacy from Napoleon enabled him to live independently, though deprived of his titles. Together with Gen. Montholon he published the *Mémoires de Napoléon à Sainte-Hélène* (8 vols., London, 1823). His *Examen critique* (1825) of Ségur's "History of the Grand Army" caused a duel between the two generals, and was followed by a sharp controversy with Sir Walter Scott, who accused him of having compromised his master at St. Helena. Under Louis Philippe he was made peer of France, and in 1840 accompanied the duke de Joinville on his voyage to St. Helena, to bring the remains of Napoleon to Paris. In 1849 he was elected to the legislative assembly, where he voted with the conservatives.

**GOURGUES, Dominique de**, a French adventurer, born at Mont-de-Marsan, Gascony, about 1530, died in Tours about 1593. He served in the war with Spain, was taken prisoner in Italy and put in chains in the galleys, was captured with the vessel by the Turks, and recaptured by the knights of Malta. He afterward made voyages to Africa, Brazil, and the East. In 1567 he sailed from Bordeaux, with three small vessels equipped with 100 arquebusiers and 80 sailors, to avenge the massacre of the French colonists in Florida by the Spaniards under Menendez. He landed at St. Mary's river, made an alliance with an Indian chief, who joined him with 300 savages, captured Fort San Mateo on the St. John's river, and two other forts, slaughtered most of the garrisons, and hung his prisoners on the same trees on which the French had suffered. Menendez had placed over his victims the inscription, "Not as to Frenchmen, but as to Lutherans;" and Gourgues retaliated by putting over the Spaniards whom he executed, "Not as to Spaniards, but as to traitors, robbers, and murderers." On his return to France his surrender was demanded by the Spanish ambassador, but he found asylum among his friends at Rouen, and lived in obscurity for many years. When Queen Elizabeth of England, hearing of his misfortunes, invited him to enter her service, the French king restored him to favor. Shortly before his death Dom Antonio of Portugal appointed him commander of his fleet against Philip II. An account of his expedition to Florida was published by Basanier, *Voyage du capitaine Gourgues dans la Floride* (4to, 1586). Parkman's "Pioneers of France in the New World" (1865) has a full account of Gourgues.

**GOUSSET, Thomas Marie Joseph**, a French prelate, born at Montigny-les-Cherlieux, Haute-Saône, May 1, 1792, died in Rheims, Dec. 24, 1866. He was the son of a peasant, and labored in the field until his 17th year. In 1817 he was ordained priest, and after a brief interval was appointed professor of moral theology in the seminary of Besançon, where he remained for 17 years. In 1825 he published *Exposition de la doctrine de l'Église sur le prêt à intérêt*, which showed that he was far in advance of the common opinion regarding usury. Other writings on the relations between the civil code and moral theology brought him to the notice of the government; and in 1835 he was made bishop of Périgueux, and in 1836 archbishop of Rheims. In 1850 he was created a cardinal and senator of France. Throughout his career he never forgot his humble origin, and delighted to have his aged father, clad in his homely peasant's garb, placed conspicuously in a seat of honor near himself in the services of his cathedral. His most remarkable works are *Théologie dogmatique* (2 vols. 8vo, 1844; 8th ed., 1856), and *Théologie morale* (2 vols. 8vo, 1848; 12th ed., 1862), which are to be found in almost every priest's library on both sides of the Atlantic.

**GOUT**, a painful disease affecting principally the fibrous tissues about the smaller joints, and intimately connected with an excess of uric acid and its compounds in the blood. Various names have been given according to the part affected, as podagra when in the feet, chiragra when in the hands, &c.; but all such, and probably many cases of neuralgia accompanied by oxalic deposits in the urine, are mere forms of one disease. A common attack of acute gout is generally preceded by uneasiness, indigestion, loss of appetite, nausea, and vomiting, biliary derangement, dull pains or numbness in the parts to be affected, often with feverish symptoms; but in some cases, on the contrary, the disease comes on in the midst of apparent health and well-being, and occasionally at night during refreshing sleep. In most cases it makes itself known by an acute pain in the metatarso-phalangeal joint of the great toe; different sufferers compare this to the sensations produced by the contact of a drop of cold water, or of cold or heated metal, or by twisting, dislocation, or laceration, as by a nail or wedge driven into the foot; this is accompanied by feverish symptoms, urinary sediment, extreme tenderness, restlessness, involuntary muscular contractions, sleeplessness, and perspiration; the affected joint is swollen, red, and hot. This series of symptoms may last four or five days, to be followed after a day or two by three or four others, continuing in all from two to three weeks; the severity of the attack, its persistence, its seat, and its metastases vary according to circumstances. This first warning past, the luxurious epicure may not receive another, even if he persist in his indulgences, for months, or perhaps years; but the second comes, and the third, and so on, the intervals between the attacks becoming less; though the pain be less severe, the joints are more discolored and swollen, with œdema and chalky deposits in their neighborhood; and by a sudden retrocession toward the internal vital organs, life may be seriously threatened. When gout becomes chronic the attacks are more irregular, less severe, more frequent and sudden, leaving one joint for another after slight exposure to cold and moisture, excess at table, or vivid emotions; in this form, the continuance of the pain and the fear of injuring the gouty joints render its subjects cross, fretful, and disagreeable, though persons thus affected are often able to devote themselves to serious study and important private and public business. The pathology of gout reduces itself chiefly to the abnormal presence of uric acid in the blood, and to the deposit of urate of soda in the fibrous tissue around the joints and sheaths of tendons. Gout is rare before the age of 20, and men of robust constitution and of a mixed sanguine and bilious temperament are far more liable to it than females; it may be inherited, and seems independent of climate except so far as it influences the diet of a people, the northern races

being generally less temperate in the use of stimulating food and drinks than southern nations. A life of indolent sensuality, amid the excitements and passions of civilization in cities, and the use of highly seasoned animal food with alcoholic stimulants, are the predisposing causes to this disease. A person may have a gouty diathesis, and die from the evils arising from it, without having experienced what is popularly understood as a "fit of the gout;" the gout poison (uric acid) may be eliminated from the blood in any organ rich in fibrous tissue, and from recent researches it would seem that many cases of neuralgia (*sciatica* and *hemicrania*), lithiasis, and oxaluria, with oxalate of lime deposits in the urine, are symptoms of the same morbid action, and excess of uric acid in the blood either from over production or accumulation; the habits and manner of life, the tissues most affected, and the peculiar urinary deposit, indicate the identity of the above forms of disease, and the propriety of the same treatment in all. Organic chemistry teaches that in the gouty diathesis, with excess of urates and oxalates, there is a deficiency of oxygen in the system; hence the uric acid may remain unchanged, or may be oxidized only into oxalic acid, the later remaining as such instead of undergoing further oxidation and being converted into carbonic acid and urea, in which forms it can be removed from the organism. We find gout attacking the upper ranks of society, who indulge in a highly nitrogenous diet, which tends to produce uric acid in excess, even though the normal quantity should be duly eliminated, and the disease assumes the form of urate of soda deposits in the joints; in the lower classes, consuming less animal and stimulating food, and taking in more oxygen from their daily exercise, the uric acid becomes the oxalic, and the gouty diathesis manifests itself in neuralgia with oxalate of lime in abundance in the urine. By many authors rheumatism is considered closely allied to gout; and accordingly cases of the latter disease affecting especially fibrous tissues are sometimes called rheumatic gout, a pathological hybrid as absurd and impossible as scarlatinic measles would be, as Dr. Garrod has clearly shown; a gouty person may have also rheumatism, but the two diseases are distinct and cannot pass the one into the other, the former having as a prominent character an excess of uric, and the latter of lactic acid.—There are few diseases which have more empirical remedies extolled for their cure than gout; almost every drastic purgative, diuretic, tonic, and narcotic has been pressed into the service, either for external or internal use. To say nothing here of soothing topical applications, colchicum has enjoyed, and deservedly, a great reputation in the treatment of gout and neuralgia, between the attacks and in their chronic forms; it is most efficacious when it acts upon the skin and bowels. The acetate of potash and other alkalies are in favor with

many, both for their diuretic property and as alkalizing the acid in the blood and urine. Nitro-muriatic acid has been found of advantage for supplying the oxygen necessary for the conversion of the uric into oxalic acid, and the latter into carbonic acid and urea. The judicious use of purgatives, abstinence from highly nitrogenous food and stimulating drinks, attention to hygienic rules, and avoiding exposure to dampness, cold, and fatigue of body or mind, are absolutely necessary as aids in the treatment of this disease.

**GOUVION SAINT-CYR**, *Laurent*, a French marshal, born in Toul, April 13, 1764, died at Hyères, March 17, 1830. He studied the fine arts, and in 1792 enlisted among the volunteers who marched to the invaded frontier. Being elected captain by his companions, he was attached to the staff of Gen. Custine, and in the course of a year rose to the rank of general of division. In 1796 he commanded a division of the army on the Rhine under Moreau. In 1798 he was sent to Rome to reestablish discipline in the army, which had nearly revolted against Masséna, and succeeded. After the 18th Brumaire he again served under Moreau, and defeated Kray at Biberach (May 9, 1800). In 1801 he was sent as ambassador to Spain, and in 1802 commanded the French army of observation in southern Italy. He was too independent in his conduct and sentiments to please Napoleon, who assigned him to employment which gave him no opportunity of gaining distinction. In 1808 he was sent to Catalonia, and relieved Barcelona in spite of the scanty resources placed at his disposal; but dissatisfied with the treatment he received, he sent in his resignation and left his post without waiting for his successor. This being considered a breach of discipline, he was cashiered and ordered to his country seat, where he remained for two years in a kind of imprisonment. In 1811 he was called back to service, in 1812 commanded a corps in the great army which invaded Russia, and defeated Prince Wittgenstein at Polotzk on the Düna, Aug. 17–18; for this victory he was made a marshal. During 1813 he made a heroic stand at Dresden, signing at last an honorable capitulation, which however was not sanctioned by Prince Schwarzenberg, and he and his troops were sent prisoners to Austria. He consequently took no part in the events which marked the fall of the empire. He gave in his adhesion to the Bourbons, and on the second restoration became minister of war under Talleyrand, and again in 1817. He retired in 1819, and devoted his leisure to the preparation of his *Mémoires* (8 vols., 1829–'31).

**GOVERNOR'S ISLAND**, a fortified post of the United States, lying in New York harbor, at the entrance of East river, about  $\frac{1}{2}$  m. S. of the Battery, and separated from Brooklyn by Buttermilk channel. It is about a mile in circumference, and contains Castle William, Fort Columbus, and South battery, the last commanding the entrance to Buttermilk channel.

**GOWER, John**, an English poet, born, according to tradition, in Yorkshire, though some authorities make him a native of Kent or of Wales, about 1325, died in 1408. He was a gentleman of considerable estate, and appears to have studied law and to have contracted a friendship with Chaucer. It has been said, but on insufficient proof, that he attained the dignity of chief justice of the court of common pleas. Like Chaucer he was a Lancastrian, and like him also a censurer of the vices of the clergy. Chaucer dedicates his "Troilus and Cressida" to Gower, calling him "moral Gower," and the latter in his *Confessio Amantis* introduces Venus calling Chaucer "my disciple and my poete." Gower's chief works are the *Speculum Meditantis*, a treatise on the duties of married life, in French verse, in ten books; the *Vox Clamantis*, a poem in seven books, describing in Latin elegiacs the insurrection of the commons under Richard II.; and the *Confessio Amantis*, an English poem in eight books, said to have been written at the suggestion of Richard II. Of these works the first is supposed to have perished, the second exists in manuscript copies, and the third, which was finished about 1393, was first published by Caxton in 1483. A new edition, with the life of the author and a glossary, by Dr. Reinhold Pauli, appeared in London in 1857 (3 vols. 8vo). Some smaller poems of no great merit are preserved in manuscript in the library of Trinity college, Cambridge; and Warton discovered in the library of the marquis of Stafford a volume of *balades* in French, which was printed in 1818 by Lord Gower for the Roxburghe club. Gower is known chiefly by his *Confessio Amantis*, which was undoubtedly suggested by Chaucer's English poems. Hallam says: "He is always sensible, polished, perspicuous, and not prosaic in the worst sense of the word." In his latter years he was blind.

**GOYA**, a city of the Argentine Republic, in the province and 100 m. S. of the city of Corrientes, on a small river of the same name, near its junction with the Paraná; pop. in 1869, 10,907, of whom only 1,839 were able to read. It is situated in a low, flat district, which in the rainy season is converted into a vast marsh. The city was founded in 1807, and considerably enlarged in 1850. Its industry is chiefly connected with cattle rearing.

**GOYANNA**, a city of Brazil, in the province of Pernambuco, on the river Goyanna, here crossed by two bridges, 1,200 m. N. N. E. of Rio de Janeiro; pop. about 9,000. There are several churches, a convent, a tannery, and public stores. A cattle fair is held weekly. The port, large and spacious, with sufficient depth of water for coasting craft, is 9 m. from the sea. The surrounding country is fertile, and in a high state of cultivation. The chief commerce is in cotton, sugar, rum, hides, timber, fancy woods, and castor oil, which are generally sent to the port of Recife.

**GOYAZ. I.** A central province of Brazil, lying between lat. 6° and 21° 5' S., and lon. 44° 35' and 50° 58' W.; area, 284,000 sq. m.; pop. about 151,000, besides about 12,000 independent Indians. It comprises the basin of the Tocantins above its junction with the Araguay, and the E. portion of the basin of the latter river, together with nearly the whole of the N. side of the basin of the Paranahyba. The surface is generally mountainous. The Cordilheira Grande traverses it from the extreme north to about lat. 16° S., where it unites with the Montes Pyreneos, the culminating point of which, Goyaz, has an elevation of about 9,500 ft. Several sierras extend from S. to N., forming for the most part the E. boundary, and with the Cordilheira Grande and the Pyreneos encircling the basin of the Tocantins. The main ranges are intersected by numerous subsidiary ones, from which the country slopes gradually down to the sea level. The geological structure is imperfectly known. It has been appropriately described as "a metamorphic island in a sea of sandstone, the sandstones having been swept away from the greater part of the river basins, leaving irregular metamorphic rocks exposed." The great plains and valleys lying between the mountains are watered by numerous rivers, among which is the Tocantins; this, formed by the union of the Maranhão and the Paranatinga, flows N. to its confluence with the Araguay, in the N. corner of the province, receiving in its course many considerable affluents. The Araguay, which belongs only in part to the province, is much larger than the Tocantins, and hence is properly the main stream, and is navigable for steamers, which run to Pará (Belem), at the mouth of the Amazon. Gold is found in many parts, the neighborhood of the capital being especially auriferous. Diamonds and other precious stones have been discovered in various places. The country is generally open, although there is an extensive forest tract lying near the capital. The lowlands are not well fitted for cultivation; but the highlands are fertile, producing millet, mandioca, rice, and a small species of beans. Cotton, coffee, and tobacco are produced; the grape flourishes, affording two vintages in the year. Melons, bananas, oranges, &c., abound. The vanilla bean, sarsaparilla, rhubarb, and senna grow spontaneously. Palms are numerous, especially the beautiful species known as the *buriti*, from the fruit of which is produced a beverage resembling wine. A considerable part of the province is especially adapted for grazing, and there are many cattle, horses, and swine. Wild animals and birds, especially macaws and parrots, are numerous. **II.** A city, capital of the province, on the river Vermelho, in lat. 16° 20' S., lon. 50° W., about 600 m. N. W. of Rio de Janeiro; pop. about 8,500. It is very nearly in the centre of Brazil, being almost equidistant from Pará, Porto Alegre, and the frontiers of Peru and Uruguay. The site is uneven,

but the streets are regularly laid out, although ill paved. Most of the houses are built with mud walls. The principal edifices are the governor's palace, the house of legislation, the prison, and the municipal slaughter house. One of the churches has a fine exterior. The river is here crossed by two handsome bridges. There is very little trade. The climate is salubrious, but in summer the heat is excessive. The town was founded in 1736, and was then called Santa Anna. It was incorporated as a city in 1739, when it received its present name of Goyaz, or, in full, Villa Boa de Goyaz.

**GOZO.** See MALTA.

**GOZZI, Carlo**, count, an Italian dramatist, born in Venice about 1720, died April 4, 1806. He early published some poetry, but was obliged to enlist in the army owing to pecuniary embarrassment. After three years he returned to Venice, and became the most witty member of the Granalleschi society, which was devoted to learning and also to convivial and burlesque purposes. He began to ridicule the plays of the abbatte Chiari, and ended by attacking those of Goldoni, against whom he directed his satire *La tartana degli infussi per l'anno bissestile* 1757, which made him famous. His dramatic pieces, based on fairy tales, were for a time exceedingly popular, especially *Turandote*, which Schiller adapted to the German stage. He afterward wrote tragedies. He published a complete edition of his plays in 12 vols. (Venice, 1791). Werthes translated his plays into German (5 vols., Bern, 1795), and Streckfuss prepared a German version of his fairy tales (Berlin, 1805). He facetiously gave to his autobiography the title of *Memorie inutili della vita di Carlo Gozzi* (3 vols., Venice, 1797).—His brother **GASPARO** (1713-'86) was a voluminous writer in prose and verse, but is best remembered as the author of the *Osservatore veneto* (published periodically), *Sermoni*, and other humorously critical productions. His works, including his *Difesa di Dante*, were collected in 16 vols. (1818).

**GRAAF, Regnier de**, a Dutch physician, born at Schoonhoven in 1641, died in Delft, Aug. 17, 1673. He was especially distinguished for having originated the discovery that reproduction takes place in the viviparous as well as in the oviparous animals by means of ovarian eggs, and that all animals are therefore essentially oviparous. The "Graafian vesicles" of the mammalian ovary were discovered and described by him, although he mistook their exact nature and considered them as true eggs, while they have since been shown to be only the receptacles within which the microscopic egg is contained. He also acquired a wide reputation by his investigations on the pancreatic juice. His works are: *Disputatio Medica de Natura et Usu Succi Pancreatici* (Leyden, 1664); *De Virorum Organis Generationi inservientibus*, &c. (1668); *Epistola de nonnullis circa Partes Genitales novis inventis* (1668); *Tractatus Anatomico-Medicus de Succo Pancre-*

*atici Natura et Usu* (1671); and *De Mulierum Organis Generationi inservientibus* (1672).

**GRAAL**, or **Grail**, the Holy (in old French, *san gréal*; in old English, *sancgreall*; either from Fr. *saint*, holy, and the Celtic *greall*, Provençal *grazal*, and mediæval Latin *gradalis*, a vase or cup, or from the French *sang réal*, the "real blood" of Christ), one of the leading themes of mediæval romance, fabled to have been the cup or chalice used by Christ in the last supper, and in which he changed the wine into his blood. This chalice, preserved by Joseph of Arimathea, had also received the blood which flowed from the side of Christ on the cross. So says the apocryphal gospel of Nicodemus; but no early mention is made of it by either profane or ecclesiastical writers. In the 12th century, at the dawn of romantic literature, it reappeared as the central subject of the prophecies of Merlin, and the object of the adventurous quest of the knights of the round table. Romance mixed it up with the struggles in Spain between Moors and Christians, and with the foundation of the order of templars in Palestine. In the Arthurian romances Joseph of Arimathea (sometimes confounded with a bishop named Joseph sent by St. Augustine from Africa to England), on his arrival in Britain, consecrated his son first bishop of the island, and made his Christian relatives kings instead of the British pagan kings. Kept in prison by the Jews during the 50 years which immediately followed the death of Christ, he had been preserved from the approaches of old age by the possession of the holy graal, and was released by the Saviour in person, who taught him the words of the mass, and bade him renew daily the sacrament of the last supper. The holy graal lay thus at the foundation of the Christian priesthood. St. Joseph of Arimathea, in some forms of the legend, was the ever-living possessor of the precious relic; in others he died after the lapse of several centuries, bestowing his authority and the holy graal on his son, who in his turn died after consecrating one of his relatives as his successor. The last possessor, a contemporary of King Arthur, unmindful of his holy trust, sinned, and forthwith the holy vessel disappeared and was lost. The knights of the round table undertook the task of recovering it; but it baffled the seekers, as no one could see it who was not a virgin in body. Lancelot of the lake had arrived at the door of the chamber where the holy graal was; warned to depart, he nevertheless ventured to look in, "and saw a table of silver and the holy vessel covered with red samite, and many angels about it, whereof one of them held a candell of wax burning, and the other held a crosse and the ornaments of the altar." Having dared to enter, a blast of fire smote him to the ground, where he lay "twenty-four days and as many nights as a dead man." It was reserved to Sir Galahad, who was possessed of perfect purity, to behold it peacefully before his death. Immediately after

this event the holy grail was taken up to heaven. In other romances Sir Percival is distinguished in the place of Sir Galahad. At a later period several churches in France and Italy claimed to possess the holy grail; and in 1101 the crusaders obtained a cup which was believed for some time to be identical with it, and which is still preserved in the cathedral of Genoa.—The *Queste du Saint Graal* is among the longest of five great romances composing the Arthurian cycle. The *Percival* and *Titular* of Wolfram von Eschenbach treat the same subject. See also Tennyson's "Idyls of the King," and "History of the Holy Grail," edited from MS. by F. J. Furnivall (London, 1874).

**GRACCHUS. I. Tiberius Sempronius**, a Roman statesman, born about 168 B. C., died in 133. His father, Tiberius Gracchus, had been censor and consul, and had twice obtained a triumph. His mother, Cornelia, daughter of Scipio Africanus, had remained a widow, devoting herself to the education of her children, in which she was assisted by eminent Greek teachers. Tiberius, the oldest, made his first campaign in Africa under his uncle Scipio, and next filled the office of quaestor under the consul Mancinus in his unlucky campaign against the Numantines. The high regard in which the latter held both his father and his uncle induced them to grant to Tiberius, with whom alone they would treat, the favorable terms which saved the Roman army. But the senate refused to ratify the treaty, and had resolved to send back Mancinus and all his officers, when Tiberius interfered and saved the officers, the consul alone being given up. At the close of 134 he was elected tribune, and commenced his career as a political agitator. The multitude of slaves brought into Italy by the long and frequent wars had taken the place in agricultural occupations of the original farmers, while the small proprietors, during the protracted terms of military service, had been bought out by the rich. Thus all Italy was owned by a few large proprietors, who employed slave labor almost exclusively in the cultivation of the soil. The city at the same time was crowded with veteran soldiers, many of whom had thus lost their estates and all of whom were needy. Prompted by his own ambition and abetted by his mother and friends, Tiberius from the commencement of his tribuneship talked openly of reviving the Licinian law, by which no man could hold more than 500 *juga* (about 330 acres) of land, and thus the surplus would become the property of the poor citizens. He framed a modification of the Licinian law (see *AGRARIAN LAWS*), which he proposed to the tribes, and which was firmly resisted by the patricians and the wealthy. Three commissioners were to be appointed to superintend the working of the new law; and crowds hastened to Rome to take sides with Tiberius or the senate. Meanwhile the latter had obtained the veto of M. Octavius Cæcina, the other tribune, and thus each time the law was proposed the proceed-

ings were quashed. Tiberius, incensed at this mode of opposition, exercised his veto on other questions, stopping the public supplies, and the government came to a standstill. It was evident that one or both of the tribunes must retire from office. Gracchus at length put the question to the tribes, and it was voted to eject Octavius, who was dragged from the tribune's chair. The agrarian law was passed immediately, and Tiberius, his brother Caius, and his father-in-law Appius Claudius, were appointed commissioners. Thereupon the senate refused to vote Tiberius more than a denarius and a half (about 20 cents) a day for his expenses as a public officer. At this juncture Attalus, king of Pergamum, died, bequeathing his kingdom and treasures to the Roman people. Gracchus forthwith proposed to divide the treasure among the recipients of land under the new law, and to give the popular assembly, instead of the senate, the management of the kingdom. He was formally accused of aspiring to be king, and made a lame defence before the people. Seeing his popularity waning, he sought to be elected tribune for a second term; and this being demurred to as illegal, a whole day's discussion ensued. Next morning, learning that the senate would oppose his election by force, he armed his followers, and was proceeding to clear the capitol when Scipio Nasica at the head of the senators attacked his partisans, and slew 300 of them, as well as Tiberius himself. **II. Caius Sempronius**, brother of the preceding, born about 159 B. C., died in 121. At the death of Tiberius he was left with Appius Claudius as commissioner for carrying out the agrarian law, but abstained from taking any part in politics for several years. In 124 he returned to Rome from Sardinia, where he had been consul's quaestor under L. Aurelius Orestes, was immediately summoned before the censors to give an account of his administration, defended himself successfully, and became a candidate for the tribuneship. He was elected, and commenced by having a law passed aimed at Popilius, who had persecuted his brother's friends. Popilius fled from Rome, and was banished from Italy. Next came a poor-law, by which a monthly distribution of grain was to be made to the people at an almost nominal price. After this he transferred the judicial power in a very great measure to the knights. These measures gained him great popularity. During his second tribuneship (122) he proposed the extension of the Roman franchise to all Italy. But this ultimately led to his ruin. M. Livius Drusus, his colleague, was persuaded by the senate to veto this law, which he did with the applause of the tribes. Furthermore, Drusus outbid him again in the popular favor by offering to establish at once twelve colonies of 3,000 persons each, who were to have their allotments free. Gracchus having seconded a parallel proposition, made by the tribune Rubrius, to colonize a spot near Carthage, the

senate sent him thither as commissioner. When he returned his popularity was gone. In the next election for tribunes his name was omitted. The law founding the colony near Carthage had been unpopular, and soon after his return it was proposed to repeal it. This he resisted, uniting with Fulvius, a commissioner of the agrarian law, and inciting the populace to acts of violence. In the tumult one of the opposite party was slain by a follower of Gracchus, and the senate named the consul Opimius dictator. He summoned Gracchus and Fulvius to answer the charge of murder. Gracchus submitted, but his partisans were in arms, and a conflict ensued. He had crossed the Tiber and taken refuge in a grove of the Furies, where, hard pressed by his enemies, he commanded his servant to slay him. He is represented as a man of surpassing eloquence.

**GRACES, The** (Lat. *Gratiæ*, Gr. *Χάριτες*), mythological beings, generally described as daughters of Jupiter, but called by some daughters of Apollo, and by others of Bacchus; their maternity is still more undecided. The Spartans and Athenians recognized only two Charites, but Hesiod enumerates three, whom he names Euphrosyne, Aglaia, and Thalia; and this number and nomenclature generally prevailed. The Graces were the goddesses of social festivity, happiness, and mirth, the inspirers of those virtues and amenities which render human intercourse delightful, and the patronesses of whatever is graceful and beautiful in nature or in art. Great poets, painters, and sculptors were the peculiar objects of their favor. The Graces were commonly represented as the companions of other divinities, especially Apollo, Venus, and Cupid; and their attributes are made always to harmonize with those of the deity upon whom they attend. Thus as the companions of Apollo they bear musical instruments, while as those of Venus they carry myrtle, roses, or dice. They are usually represented as virgins in the bloom of life, embracing each other, and sometimes appear clothed, sometimes naked.

**GRACIAS, or Gracias á Dios** ("Thanks to God"), an inland city of Honduras, capital of a department of the same name, situated in a fertile plain, near the foot of a steep and craggy mountain, 77 m. by N. of Comayagua; lat. 14° 30' N., lon. 88° 50' W. Though now having only 3,000 inhabitants, Gracias was once a flourishing city, with a large population, attracted thither by the rich mines of the surrounding country, and was the chief entrepot for merchandise *in transitu* from Puerto Caballos to the populous region of Guatemala. It was founded in 1530 by Gabriel de Rojas, and enlarged in 1536 by Gonzalo (or more probably Pedro) de Alvarado. Until 1544 it was the seat of government of Guatemala and Nicaragua; but since then it has gradually fallen from its original splendor, the only traces of which are now visible in the parish church and the convent of La Merced. Although mi-

ning is still followed to a considerable extent, and opals of the finest quality are found in the vicinity, the inhabitants depend chiefly on agriculture for subsistence. The climate is very salubrious. Near the town a mountain torrent, one of the tributaries of the Rio Santiago or Venta, plunges by two successive leaps to a depth of 1,200 feet.

**GRACIAS Á DIOS, Cape**, the N. E. point of Central America, at the mouth of the large river Coco or Segovia, in lat. 15° N., lon. 83° 12' W. It was so named by Columbus, when, in his fourth voyage, after beating for many days against head winds and adverse currents, he finally succeeded in turning the angle of the continent, and taking his course southward. There is a harbor near the cape, with but 16 feet of water.

**GRACIOSA**, one of the Azores, so called from its beautiful situation and extreme productiveness, lat. 39° 5' N., lon. 28° 4' W.; area, 32 sq. m.; pop. about 12,000. Its chief exports are corn, wine, brandy, fruit, hemp, and flax. Chief town, Santa Cruz.

**GRADUATION**, the art of dividing astronomical, geodetical, and other mathematical instruments. It was formerly done by hand with ordinary dividing instruments, and so few makers possessed the requisite skill that it was very difficult to procure good instruments for the ordinary purposes of navigation; but now the operation is performed with great exactness by machines called dividing engines. Jesse Ramsden, a cloth presser, who subsequently turned his attention to engraving, being brought in contact with mathematical instrument-makers, was led to construct the engine which for many years was called by his name. At that time it was considered so valuable that the English commissioners of longitude entered into a contract with him (1775) to instruct a certain number of persons, not exceeding ten, in the method of making and using it, and to divide sextants and octants at certain prices as long as the engine remained in his possession, they becoming the purchasers for the sum of £315, and giving £300 in addition for the invention. Perfect as the instrument was then considered, it has since been greatly improved, so that it is now automatic, the whole operation of dividing a circle, after it has been placed on the engine, being performed by a motion given by the descent of a weight, or by a crank turned by hand. The engine consists of a large wheel of bell metal, the circumference being ratched into 720, 1,080, 1,440, 2,160, or 4,320 teeth, or any number which, divided by 2, 3, 4, 6, or 12, will give 360. These teeth are cut with great accuracy, and the wheel is turned on its centre by an endless screw, by which it may be moved any number of degrees or parts desired. The dividing point is fixed in a frame which admits of a free and easy motion to and from the centre. In England, Troughton, Simms, Thomas, Jones, Ross, and a few others, have been successful in making these engines,

while many others have failed. On the continent of Europe they were first made automatic, and other improvements were also made in them. Gambey of Paris has so arranged his as to divide an instrument without any eccentricity, even when placed in a slightly eccentric position on the engine. Oertling of Berlin has an arrangement for correcting any original errors in the teeth while dividing, and other mechanists of celebrity have constructed them to suit their own views, and for their own use. In the United States there is a large one belonging to the coast survey, made by Simms of London, and afterward made automatic by Saxton; also one in Philadelphia made by Young, and one in New York by the Messrs. Blunt, both of which are automatic. There is no branch of the mechanic arts which requires more skill in the use of tools, more geometrical knowledge, and greater patience, than the construction of a circular dividing engine. The large astronomical instruments are divided in a different manner, and, unless placed on a large engine from which the divisions may be in a manner copied, are original divisions. Troughton, Simms, and Jones of London have used movable microscopes with micrometers; while others on the continent of Europe have availed themselves of the feeling lever, a powerful instrument for that purpose invented by the astronomer Bessel. Straight line divisions for scales, &c., are made by means of a screw, a milled roller, or a wedge which is employed to move a platform sliding freely beneath a cutting frame, and carrying the scale to be divided. In the use of the screw much depends on its accuracy, and, with regard to the roller or wedge, on the working or manner of applying them. When great accuracy is required, the divisions are tested by means of two microscopes, and an error can be detected of  $\frac{1}{86,500}$  of an inch. The ruling machines used by engravers in this country are well calculated for this purpose.

**GRÆVIUS, Johann Georg** (GRAEFFE), a German scholar, born in Naumburg, Jan. 29, 1632, died in Utrecht, Jan. 11, 1703. He had begun to study law at Leipsic, when, meeting with Gronovius at Deventer, he determined to begin his education over again, devoting himself to belles-lettres. After remaining two years at Deventer, he passed to Amsterdam, where he studied history under Morus and Blondel, and abjured Lutheranism for Calvinism. In 1658 he succeeded Gronovius in the atheneum of Deventer, and in 1661 obtained the chair of eloquence in the academy of Utrecht, to which was attached in 1667 that of politics and history. Louis XIV. gave him a pension, and the universities of Heidelberg, Leyden, and Padua in vain sought to attach him to them. Among his works are editions of Hesiod, Cicero, Catullus, Tibullus, Propertius, Suetonius, and Florus, and *Thesauri* of Italian antiquities.

**GRÄFE. I. Karl Ferdinand von**, a German surgeon, born in Warsaw, March 8, 1787, died in

Hanover, July 4, 1840. He graduated as a doctor of medicine at Leipsic in 1807, and in 1811 became professor of surgery in Berlin. During the war with Napoleon he superintended the military hospitals, and after the restoration of peace (1815) he became a member of the medical staff of the army. Students from all parts of the world attended his lectures, and on his visit to England he was the guest of the king. In Paris Dupuytren invited him to take his place as a lecturer. In 1840 he was summoned to Hanover to operate upon the eyes of the crown prince (the present ex-king George), but he suddenly died after his arrival there. The revival of the rhinoplastic process was due in a great measure to the labors of Gräfe, who propounded his system in his work *Rhinoplastik* (Berlin, 1818).

**II. Albrecht von**, a German oculist, son of the preceding, born in Berlin in May, 1828, died there, July 18, 1870. He studied mathematics and the natural sciences, and afterward medicine, at Berlin, Prague, Vienna, and Paris, devoting himself particularly to ophthalmology, and founded in Berlin a private establishment for the treatment of the eyes. He was also professor of ophthalmology in the university. He was distinguished for great practical and scientific acquirements in ophthalmology, the leading journal of this department of medicine at Berlin, *Von Gräfe's Archiv für Ophthalmologie*, being conducted under his name with the collaboration of Profs. F. Arlt, F. C. Donders, and Th. Leber. Most of Von Gräfe's important contributions were published in this journal. These were papers on the "Physiology and Pathology of the Oblique Muscles of the Eyeball," on "Double Vision after Operations for Strabismus," on "Diphtheritic Conjunctivitis," on the "Effect of the most refrangible Solar Rays upon Sensation," on the "Treatment of Glaucoma by Iridectomy," on the "Cerebral Causes of Blindness," and on a modified form of the operation for the extraction of cataract. He was also a frequent contributor to the medical society of Berlin and to various medical journals. **III. Alfred Karl**, nephew and some time assistant of the preceding, born Nov. 23, 1830. In 1858 he graduated at Halle, afterward became professor there, and founded an ophthalmic institute, which is visited by several thousand patients annually. He was the first to obtain a recognition of the study of diseases of the eyes as a special science in the Prussian universities. He has published *Klinische Analyse der Motilitätsstörungen des Auges* (Berlin, 1858), *Symptomenlehre der Augenmuskellähmungen* (1867), and *Ein Wort zur Erinnerung an Albrecht von Gräfe* (1870).

**GRÄFENBERG.** See PRIESSNITZ.

**GRAFTING**, the process in horticulture by which a portion of a plant is made to unite with another plant, whether of the same kind or of another variety or species. The plant upon which the operation is performed is called the stock; the portion inserted in or joined

with it the scion or graft. No attempts toward grafting plants on others which do not belong to the same natural order have been successful. Generally speaking, varieties succeed best on varieties, species on species, or species and varieties on allied genera. All our cultivated fruits, for instance, are improved varieties of some original species. Out of thousands of varieties raised from the seeds of some previous excellent variety, it is not likely that any will be precisely like the immediate parent; some few may be equal or superior to it, but the great majority will be inferior. When a new and decidedly valuable variety occurs, it becomes a matter of importance to perpetuate it in as many individual plants as possible, and this, with trees, is usually done by grafting. The trifling effect that the stock has upon the scion enables the poorer varieties to be employed in furnishing the trunk and root to the smaller and younger scion. A piece of well ripened wood, in the form of a twig of the growth of the previous season having three or four buds upon it, is thus transferred to the poorer kind, and forms a living extremity, which extends itself into branches and forms a new head or top. Fruit trees are grafted on plants of their own kind, called free stocks, or they are grafted upon a related variety or species to accomplish some particular end. Certain stocks induce early fruiting and a dwarfed growth; to dwarf the apple, it is grafted upon the paradise, a distinct variety of apple; the pear is dwarfed by grafting upon the quince. A species of cherry called the mahaleb (*prunus mahaleb*) is used for dwarfing the cherry, and the sloe and the beach plum for the plum. The peach upon its own roots does not grow well in stiff and cold soils, and for such situations it is worked upon a plum stock. The pear will grow when grafted upon the apple, but the union is short-lived; it is also sometimes grafted upon the thorn and mountain ash, but such unions are a matter of fancy rather than utility; nurserymen use only the stocks we have mentioned. The raising of stocks is an important part of the nurseryman's business; though a tree may be grafted at almost any age, in nurseries where hundreds of thousands are worked every year the stocks used are as small as practicable. Free stocks for the apple and pear are raised from seeds, while the dwarfing paradise and quince stocks are grown from layers and cuttings. Most of the grafting in nurseries is done indoors in the winter. The stocks, which are a quarter of an inch or more in diameter, are taken up in the autumn and buried in an accessible place; when worked, the root is shortened, the top cut off, and the scion inserted at the "collar," or where root and stem join. The grafted roots are set in boxes of sand and kept in a cellar until they can be planted in spring. The operation is performed with great rapidity, and several mechanical appliances have been devised for facilitating the work. Sometimes pieces of the root

are used as stocks, but there has been much discussion and great difference of opinion as to the value of the trees so produced. Stone fruits are more difficult to graft than the apple and pear, but if it be done sufficiently early in spring the plum may be so treated very successfully; the peach is rarely grafted at the north, but it succeeds at the south; this fruit is usually propagated by that form of grafting called budding. Although fruit trees are grafted with scions of ripened wood, there are some trees which will only succeed when green wood is used for both scion and stock; this kind of grafting is called herbaceous. Many evergreens can be grafted in the ordinary way, but the pines only succeed with herbaceous grafting, and the same may be said of some nut-bearing trees. Ornamental trees of various kinds are propagated by grafting, especially where it is desired to perpetuate some individual peculiarity, such as a pendent or weeping habit, or foliage of an unusual shape or color. Some weeping trees which are naturally low, as the weeping beech, ash, and poplar, form elegant specimens when grafted upon a stock 8 or 10 ft. high. Among ornamental trees and shrubs grafting is resorted to as the most rapid means of propagation: sometimes a variety cannot be multiplied readily from cuttings, but can be grafted upon some related stock that will grow rapidly. The choicer species of clematis, now so much prized as ornamental climbers, take root with great difficulty, while some of the older kinds strike root freely; the florist grows these from cuttings, and grafts the more difficult subjects upon their roots. The fine double camellias will not grow from cuttings, but are propagated by grafting upon the single kinds which readily do so. Epiphyllums and other trailing cactuses make fine plants by grafting them upon a stout stem of *cereus triangularis* or one of the pereskias. Successful grafting of the apple upon the maple, the rose upon the black currant, and the like, is impossible, although instances of it are often narrated.—The utility of the operation of grafting depends upon the fact that a bud is the representative of the tree from which it is taken; it has the possibility of unlimited development; and as it will, if allowed to extend into a branch on the tree where it has formed, repeat all the characters of the tree, so when taken from the tree which produced it and planted as it were in the substance of another tree, it will develop a branch like the parent tree, and not like the stock with which it is united. Between the wood and bark of exogenous trees, including all northern fruit trees, there is a layer in which the forces of vegetation are most active; here the wood of the tree receives each year a layer of new wood, outside of the old, and the inner bark has deposited upon it a new layer upon the inside of that of previous years. This portion, which is neither perfect wood nor bark, but the place where both are

being formed, is called the *cambium* layer. It is this which, if a cut be made in a tree, sends out a new growth to close over and repair the wound; and it is upon the extraordinary vitality of this cambium that the success of grafting depends. The mechanical operations of grafting are various, but they all have for their object the bringing of the newly forming wood and bark of the scion into the closest possible contact with those of the stock. As a general rule, grafting is most successful when the scions are quite dormant, but the forces of vegetation in the stock are active. Fruit-tree scions are cut at any time after the fall of the leaf before the buds begin to swell, and kept in damp sand or saw dust to prevent drying.—Cleft grafting is in this country the most common and likewise the most clumsy method, and yet very often the most successful. It is practised upon stocks from an inch to several inches in diameter. The branches of old trees are renewed by this method, the grafts being inserted in the branches. Sometimes the entire tree of four or five inches diameter is cut to a bare stock and used in the same manner. The stock, whether trunk or branch, is cut over horizontally with a sharp saw, and the surface pared smooth with a knife; a cleft about two inches deep is made in the stock with a grafting knife and mallet; the scion to be grafted is prepared by sloping its lower end in the form of a wedge about an inch and a half long, leaving it a little thicker on the outer edge. The cleft being kept open with a wedge, the scion is carefully

loam and cow dung, or with grafting wax, to exclude the air and to facilitate the union. Until a few years ago clay and loam were exclusively used, but grafting wax is neater and more effective. Various compositions are in use; they consist of resin and wax melted to-

FIG. 3.—Whip Grafting on the Collar.

gether, with lard or linseed oil, and should be of such consistency as to remain plastic in cool weather, yet not run in hot weather. It is best applied by means of strips of well worn muslin or calico saturated with the composition. For root grafts, well waxed cotton twine, or paper waxed on one side, may be used. Where the stock is large two scions are put in on opposite sides, but with small stocks only one is used, and the stock at the side opposite to the scion is cut in a sloping manner to facilitate healing.—Another process, called whip or tongue grafting, is considered the most expeditious. The stock upon which it is performed must be slender, from the size of a goose quill to any diameter which coincides with the thickness of the graft. Some smooth, clear part of the stock being selected, it is sloped on one side with a knife to a very acute angle. A scion having two or more buds, and of the size to match the stock, is cut with a slope to correspond with that upon the stock; then upon each slope or cut surface is cut a tongue; the scion and stock are locked together by means of these tongues in a manner that will be understood by an examination of the engraving. The barks of both being made to correspond, a piece of waxed cloth or waxed twine is wound round them to hold them in place. After the graft pushes its buds, the binding should be loosened and finally removed, when the adhesion is completed. This method is used in root grafting, and may be practised also on flowering shrubs.—In saddle grafting, the scion is cleft instead of the stock; the stock is pared away on each side to an acute angle, so as to allow the scion to sit or ride

pushed down to the place fitting its inner bark on one side, so that the inner edges of the bark of stock and scion may coincide. The wedge is then withdrawn, and the scions are retained in place by the springing together of the cleft, when the graft is covered with a mixture of

upon it, and the union of the edges of the barks made as complete as possible on each side.—Crown grafting is by many preferred to cleft grafting, as there is no split made in the stock, which often leads to decay; it is practised upon large trees of which the wood is too hard and stubborn to be cleft, or upon small stocks. Several scions are pared away on one side of the lower end for about two inches, so as to make that side flat and leave a shoulder forming a right angle with it. The head of the stock being sawn off horizontally, and the cut portion smoothed, the bark is gently raised from the wood and thin wedges inserted. The scions are now pushed under the bark, their shoulders resting on the crown of the stock; the wedges being withdrawn, the whole is covered with wax or waxed cloth. After the grafts have grown, and made long, tender shoots, which they will be apt to do with much rapidity and vigor, they should be secured to long stakes planted near the stock and rising above it, to

FIG. 4.—Crown Grafting, showing the completed operation and an enlarged view of the scion.

prevent the wind from breaking off the newly formed top at the junction with the stock; or where the grafts are in the head of a tree, their vigor is controlled by pinching.—Sometimes it is essential to replace limbs that have been broken from young trees, or from branches of older ones, and to restore the symmetry of form; and this is done by side grafting. Here the bark and a little of the wood is sloped off from the side of the trunk or of the branch, and the lower end of the scion is cut so as to fit the part as near as possible; it is then fixed in the branch or trunk, first tonguing both as in whip grafting, tying them with bast, and claying or waxing over. Another form of side grafting is used on the camellia and other hard-wooded shrubs; a long, nearly perpendicular cut is made in the stem, in which the scion is placed.—Inarching is only a kind of grafting, and is employed where the cut scion is not easily united to the desired stock. Two branches, or two stocks of the

two distinct plants, are brought close together, and the prepared surfaces are matched and tongued, as in whip grafting; after a while a perfect union will take place, when the inarched portion is to be separated from its parent root, and it henceforth becomes the branch or top of its new foster mother. The two plants to be inarched must be brought near to one another, which is usually accomplished by having one of them in a pot. In some cases the same object is effected by placing the lower end of the branch to be inarched in a bottle, which is kept supplied with water.—Budding is only a variety of grafting in which a single bud is used instead of a scion with several; it is also called shield grafting. (See BUDGING.)—The practice of grafting seems to have been long known; but the processes have multiplied with the discoveries and improvements in horticulture, and others besides those mentioned here are employed for particular subjects. A full account of all the processes known will be found in *L'Art de greffer*, by Baltet. Du Breuil's "Arboriculture," Barry's "Fruit Garden," and Thomas's "Fruit Culturist" may also be consulted for practical details.

FIG. 5.—Inarching.

**GRAFTON**, a W. county of New Hampshire, bounded W. by the Connecticut river; area, 1,463 sq. m.; pop. in 1870, 39,103. It has a mountainous surface, containing some of the celebrated summits of the White mountains and the Franconia range. Much of the land is devoted to pasturage, but parts of it are susceptible of high cultivation. The Northern (N. H.) and its Bristol branch, the White Mountain, and the Boston, Concord, and Montreal railroads pass through the county. The chief productions in 1870 were 57,802 bushels of wheat, 198,165 of Indian corn, 390,172 of oats, 1,078,208 of potatoes, 1,095,623 lbs. of butter, 189,602 of cheese, 446,197 of wool, 650,445 of maple sugar, 26,377 of hops, and 140,220 tons of hay. There were 7,135 horses, 12,748 milch cows, 6,685 working oxen, 14,562 other cattle, 86,681 sheep, and 4,302 swine. The number of manufactories was 646, with an aggregate capital of \$2,362,735; value of products, \$5,012,033. The most important were 5 of agricultural implements, 15 of clothing, 1

of elastic sponge, 7 of furniture, 14 of gloves and mittens, 5 of hosiery, 3 of iron castings, 11 of dressed skins, 8 of paper, 4 of shoe pegs, 25 of starch, 6 of woollen goods, 69 saw mills, 10 tanneries, 5 currying establishments, and 6 flour mills. Capital, Haverhill.

**GRAFTON**, a town of Worcester co., Massachusetts, on the Blackstone and Quinsigamond rivers, and on the Blackstone canal and the Boston and Albany and Providence and Worcester railroads, 38 m. S. W. of Boston; pop. in 1870, 4,594. It comprises several villages, and is extensively engaged in manufacturing, the canal and rivers furnishing water power. There are 8 cotton mills, with 30,170 spindles, several currying establishments, and extensive boot and shoe factories. The town has also mica quarries, two national banks, 18 public schools, including a high school, and seven churches.

**GRAGNANO**, a town of S. Italy, in the province of Naples, at the foot of Monte Pendolo, 19 m. S. E. of Naples; pop. about 10,000. It is the seat of a bishop, and has manufactures of macaroni and a considerable trade in wine.

**GRAHAM. I.** An extreme W. county of North Carolina, formed since the census of 1870 from Cherokee co., bounded N. E. by the Tennessee river, and separated from Tennessee by the Iron mountains; area, about 300 sq. m. The surface is mountainous; the soil of the valleys is fertile. Capital, Fort Montgomery. **II.** A N. W. unsettled county of Kansas; area, 900 sq. m. It is intersected by the South fork of Solomon river, and drained by Saline river.

**GRAHAM, Isabella**, a Scottish philanthropist, born in Lanarkshire, July 29, 1742, died in New York, July 27, 1814. Her maiden name was Marshall. In 1765 she married Dr. John Graham, an army surgeon, and went with him to Canada and to Antigua, where he died in 1774. Returning to Scotland, she taught school in Paisley and in Edinburgh. In 1789 she came to New York, and established a seminary for young ladies. Before leaving Scotland she originated the "Penny Society," now known as the "Society for the Relief of the Destitute Sick;" and through her efforts in part or entirely, the "Society for the Relief of Poor Widows," the "Orphan Asylum Society," the "Society for Promoting Industry among the Poor," and the first "Sunday School for Ignorant Adults," were established in New York. She aided also in organizing the first missionary society and the first monthly missionary prayer meeting in the city; was the first president of the Magdalen society; systematically visited the inmates of the hospital, and the sick female convicts in the state prison; and to hundreds of families distributed Bibles, as well as tracts prepared under her own direction. Her memoirs were written by Dr. Mason (8vo, 1816), and her letters and correspondence, selected by her daughter, Mrs. Bethune, were published in New York in 1838.

**GRAHAM, John**, Viscount Dundee and Lord Graham of Claverhouse (by which latter title

he is most generally known), a Scottish soldier, born near Dundee in 1643, killed at the battle of Killiecrankie, July 17, 1689. Educated at the university of St. Andrews, he served both the French and the Dutch as a soldier of fortune from about 1670 to 1677, when he returned to England. Letters of recommendation from the prince of Orange to Charles II. caused him to be appointed captain of one of the troops of dragoons which the king was sending into the western lowlands to force the Covenanters to comply with the established religion. His own merciless severity was so well seconded by his troopers, that his name is held in lasting execration. Defeated at Drumclog by the exasperated Covenanters, he took a fearful revenge at Bothwell bridge, and continued his atrocities through the western shires. Ennobled in November, 1688, by James II., he ardently espoused the king's cause against the prince of Orange, attended the parliament convened in Edinburgh to arrange the succession to the crown, and, becoming alarmed for his personal safety, fled from the city with a squadron of horse. Several disaffected clans and a body of Irish joined him. At the pass of Killiecrankie he routed the troops of William III., and fell by a chance shot in the moment of victory. His qualities as a soldier and a politician, which were conspicuously displayed during the last few months of his life, have diverted attention somewhat from his crimes; and Sir Walter Scott, in his "Old Mortality," has presented a vigorous though highly colored picture of him. One of the latest attempts to relieve his character from the odium which attaches to it was made by Prof. Aytoun in the appendix to his "Lays of the Scottish Cavaliers." See also "Memorials and Letters illustrative of the Life and Times of John Graham of Claverhouse, Viscount Dundee, by Mark Napier" (3 vols., Edinburgh, 1859-'62).

**GRAHAM, Sylvester**, an American reformer, born in Suffield, Conn., in 1794, died in Northampton, Mass., Sept. 11, 1851. Almost from childhood he was dyspeptic and rheumatic, and having tried successively farm labor, paper making, travelling with a horse dealer, shop-keeping, and teaching, was driven from them all by feeble health and symptoms of consumption. In 1823 he entered Amherst college to prepare for the ministry. There the fervor of his elocution was ridiculed as theatrical, and this almost determined him to seek some other profession; but in 1826 he married, and soon after became a Presbyterian preacher. In 1830 the Pennsylvania temperance society engaged him as a lecturer, and he took up the study of physiology and anatomy, from which he was convinced that the only permanent cure for intemperance was to be found in correct habits of living and judicious diet. This idea, which he extended to the cure of diseases generally, was set forth in his "Essay on Cholera" (1832),

and in a course of lectures which he delivered at various places and published under the title "Graham Lectures of the Science of Human Life" (2 vols., Boston, 1839). He also published a "Lecture to Young Men on Chastity," which made a great sensation, and a treatise on "Bread and Bread Making." Bread made from unbolted flour still bears his name. A few years before his death he began a "Philosophy of Sacred History," intended to show the harmony between Scriptural teachings and his views on dietetics; he finished only one volume of it, which was published posthumously.

**GRAHAM, Thomas**, a Scottish chemist, born in Glasgow, Dec. 20, 1805, died in London, Sept. 15, 1869. He studied at the universities of Glasgow and Edinburgh, and after graduating opened a laboratory in Glasgow and lectured on chemistry at the mechanics' institute. He was professor at the Andersonian university in Glasgow from 1830 to 1837, and at the university college in London from 1837 to 1855. Having, as a non-resident assayer, submitted all the specie in the mint to a uniform scientific standard, he became, in February, 1855, Sir John Herschel's successor as master of the mint, and held this office till his death. He was one of the founders and the first president of the chemical society of London, for many years president of the Cavendish society, and a fellow and twice vice president of the royal society, which gave him many medals. He conducted many physical and chemical investigations for the government, including one of especial interest on the effect of hail storms in the Newcastle coal mines, reporting on the ventilation of the houses of parliament, and in 1851, with Professors Miller and Hoffmann, on the quality of the metropolitan water supply. He discovered the law of diffusion of gases and the polybasic character of phosphoric acid; demonstrated the existence of a diffusive power in liquids resembling that in gases, to which he applied the name of *omosis*, and determined its relation to *endosmosis* and *exosmosis*; expounded new theories on the composition of salts, and extended his researches to the transpirability of gases. His discoveries and other labors are embraced in his "Elements of Chemistry" (London, 1842), edited with notes and additions by Dr. Robert Bridges (Philadelphia, 1852; new eds., 2 vols., London, 1856-'8, and 1865; German translation by Otto, 3d ed., Brunswick, 1857). He contributed important papers to the "Philosophical Transactions," and the annals of the chemical and other scientific societies. His genius is highly appreciated in Germany, and A. W. Hoffmann published in Berlin (1870) his *Gedächtnissrede auf Thomas Graham*. A bronze statue of Graham was placed in George square, Glasgow, in 1872.

**GRAHAM, William Alexander**, an American statesman, born in Lincoln co., N. C., Sept. 5, 1804, died in Saratoga, Aug. 11, 1875. He was educated to the law, and in 1833 entered

the lower branch of the state legislature, of which he was several times elected speaker. He represented North Carolina in the United States senate between 1841 and 1843, and was governor of the state from January, 1845, to January, 1849. On the accession of Mr. Fillmore to the presidency he was appointed secretary of the navy, an office which he filled until June, 1852, when, receiving from the whig national convention the nomination for vice president, he resigned the secretaryship. During the last year of the civil war he was a senator in the confederate congress, and in 1866 he was a delegate to the union convention in Philadelphia.

**GRAHAM ISLAND**, or *Isle of Julia*, a volcanic island, which appeared in the Mediterranean in July, 1831, and disappeared toward the close of October. The locality was about midway between Sciacca in Sicily and the island of Pantellaria, lat. 37° 8' N., lon. 12° 42' E. The depth of water had been found, a few years before, to exceed 100 fathoms. An earthquake shock was felt over the spot three weeks before the appearance of the island; and on July 10, a few days before land was observed, a waterspout was seen by a Sicilian navigator, which was succeeded by an immense column of steam rising to the estimated height of 1,800 feet. Fire was seen on the 17th by the master of the brig *Adelaide* of London. On the 18th the Sicilian captain, repassing the spot, found a small island, 12 ft. out of water, with a crater in its centre, ejecting volcanic matter and immense columns of vapor. About the same time Commander Swinburne, R. N., reported it to be 70 or 80 yards in external diameter, and its lip as thin as it could be consistent with its height, which might be 20 ft. above the sea at the highest point. On July 23, as reported and sketched by Mr. Russell of H. M. ship *St. Vincent*, the circumference of the island was three fourths of a mile, and its highest point 80 ft. above the water. At that time columns of water were ejected to the height of 800 to 1,000 ft., and scoriæ were thrown, it was supposed, twice as high. The first landing was effected on Aug. 3, by Capt. Senhouse of the *St. Vincent*, who hoisted the British flag, and called the island by the name which was afterward adopted by the royal and geographical societies. The island was then from  $1\frac{1}{4}$  to  $1\frac{3}{4}$  m. in circumference, and its highest point was about 180 ft. above the surface. A deep circular crater lay between two longitudinal hills, by which it was entirely shut in except for about 250 yards on its S. E. side, where a bank only 3 ft. high separated it from the sea. The crater was filled with boiling salt water of a dingy red color, from which rose a nauseous and oppressive vapor. The only gas evolved in large quantity was carbonic acid. Some authorities have made it about this time to be 3 m. in circumference, with a maximum height exceeding 200 ft. On Aug. 25 it was reduced to 2 m., and on Sept. 3 to

only  $\frac{3}{4}$  m., with a maximum height of 107 ft. The crater was then 780 yards in circumference. The materials which composed the island were scoriae, pumice, and lapilli, arranged in regular strata which sloped steeply away from the crater. The only substances found not of volcanic nature were fragments of dolomitic limestone. No lava was ever seen to flow, and no solid beds were formed which could resist the action of the waves. By these all the loose materials were washed away, so that at the close of October it may be said to have entirely disappeared. Two years afterward Capt. Swinburne found a dangerous reef at the spot, in the centre of which was a black rock of the diameter of 26 fathoms, from 9 to 11 ft. under water. Around it, extending 60 fathoms to deep water, were banks of black volcanic stones and loose sand. The black rock in the centre was supposed by Lyell to be solid lava which rose in the crater and became solidified and formed a dike. Another shoal 450 ft. S. W. of the great reef marked the spot where another outbreak of boiling water and steam had been observed in the month of August, 1831. In July, 1863, the island reappeared, and in a few weeks rose to the height of 200 or 260 ft.; but it was soon demolished by the wash of the waves. The volcano had appeared once or twice previous to 1831. It is said that a smoking island existed in this spot about the year 1801, and the shoal is marked in old charts. This island has been called by seven names, and is sometimes still known as *Ferdinanda*.

**GRAHAME, James**, a Scottish poet, born in Glasgow, April 22, 1765, died near that city, Nov. 30, 1811. He was educated at the university of Glasgow, went to Edinburgh, and became a writer to the signet in 1791, and a member of the faculty of advocates in 1795. But the legal profession had always been distasteful to him, and in the spring of 1809 he went to England, where he was ordained a minister of the established church, and became curate of Shipton, Gloucestershire, and afterward of Sedgfield, in Durham. His principal poetical works are "The Sabbath," "Mary, Queen of Scots," "British Georgics," and "The Birds of Scotland."

**GRAHAME, James**, a Scottish historian, born in Glasgow, Dec. 21, 1790, died in London, July 3, 1842. He studied at St. John's college, Cambridge, but soon terminated his connection with that institution, and after preparatory studies was admitted an advocate at the Scottish bar in 1812. For nearly 14 years he practised his profession, until he was obliged through ill health to seek a more genial climate. Settling in the south of England in the spring of 1826, he devoted himself to the preparation of a history of the United States. His early education, his religious views, which were those professed by the Scotch Covenanters and Puritans, and his zeal in the cause of civil liberty, combined to render the subject

attractive to him. In 1827 the first two volumes were published, and in 1836 a new edition appeared in 4 vols. 8vo, bringing the history down to the year 1776. The thoroughly American spirit in which the work was written interfered with its success in England, and for several years it attracted little notice in the United States; but in 1839 the author received from Harvard college the degree of LL. D., and in 1841 an article on his history by Prescott appeared in the "North American Review." Four years later an edition of his work was published at Philadelphia in 4 vols. 8vo, succeeded in 1846 and 1848 by editions in 2 vols. each, that of 1846 containing a memoir of the author by Josiah Quincy. Mr. Quincy also published a work entitled "The Memory of the late James Grahame, the Historian of the United States, vindicated from the Charges of Mr. Bancroft" (8vo, Boston, 1846). In 1837 Mr. Grahame, who for some years previous had resided at Nantes, France, began to collect materials for continuing his history, but was compelled by ill health toward the close of the year to abstain from literary labor of all kinds. His last work was a pamphlet entitled, "Who is to Blame? or Cursory Review of the American Apology for American Accession to Negro Slavery" (London, 1842). The subject had excited his attention for many years, and he had testified his sincerity by joining with his children in liberating a number of slaves they had jointly inherited from his wife. He wrote pamphlets on various social and religious questions, including a "Defence of the Scottish Presbyterians and Covenanters against the Author of the 'Tales of my Landlord;'" but the absorbing study of the best years of his life was American history. He delighted to call himself an American by adoption, and declared that his daughter was "hardly dearer to him than America and American renown." His "History of the United States" is written, according to Chancellor Kent, "with great gravity and dignity, moderation and justice."

**GRAHAM'S TOWN**, a town of Cape Colony, capital of the district of Albany, 22 m. N. N. W. of Bathurst, and 465 m. E. by N. of Cape Town; pop. about 8,000. It is pleasantly situated on an eminence surrounded by high grassy hills. The streets are wide; the dwellings provided with gardens well watered and stocked with fruit trees. There are several handsome churches, a public library, two banks, and a flourishing grammar school. It is the see of an Anglican and a Roman Catholic bishop.

**GRAIL, Holy.** See **GRAAL**.

**GRAIN** (Lat. *granum*, a seed), the smallest measure of weight in use, about equal to that of a kernel of wheat. A statute passed in England in 1266 ordained that 32 grains of wheat, taken from the middle of the ear and well dried, should make a pennyweight, 20 of which should make an ounce, 12 of which should make a pound. The pound, therefore, consisted then of 7,680 grains, but afterward of only 5,760, in

consequence of the division of the pennyweight into 24 grains. The present troy pound is 5,760 grains, and the avoirdupois pound 7,000.

**GRAIN COAST**, a part of the coast of upper Guinea, W. Africa, between Capes Mesurado and Palmas, comprising a large part of the coast of Liberia. It receives its name from the cardamom, or grain of paradise, called otherwise Guinea grains and Malagueta pepper, which is exported. (See **LIBERIA**.)

**GRAINGER**, a N. E. county of Tennessee, bounded N. W. by Clinch river and S. E. by Holston river, here navigable by steamboats; area, about 330 sq. m.; pop. in 1870, 12,421, of whom 1,030 were colored. The surface is hilly, Clinch mountain crossing the county from N. W. to S. E. The river bottoms are fertile, and the highlands are rich in iron and other ores. The chief productions in 1870 were 78,146 bushels of wheat, 353,260 of Indian corn, 86,005 of oats, 12,285 of Irish and 8,045 of sweet potatoes, and 709 tons of hay. There were 2,233 horses, 2,248 milch cows, 4,670 other cattle, 9,797 sheep, and 17,723 swine. Capital, Rutledge.

**GRAKLE. I.** A conirostral bird of the East Indian genus *gracula* (Linn.), constituting in itself the subfamily *guaculinæ* of the family *sturnidæ* or starlings. The species, especially the mina bird (*G. religiosa*), are celebrated for their powers of song and speech. (See **MINO BIRD**.)

**II.** In the United States, the name of birds of the subfamily *quiscalinæ* or boat-tails, which includes the genera *scolecophagus* (Swains.), *quiscalus* (Vieill.), and *scaphidurus* (Swains.). The genus *scolecophagus* has the bill shorter than the head, nearly straight, slender, with the edges inflexed; the wings moderate and pointed, the first quill shorter than the second, third, and fourth, which are longest; the tail shorter than the wings, flat and nearly even; tarsi as long as the middle toe, with broad scutellæ; toes long and slender, the hind toe long, and the slender claws sharp and slightly curved. The rusty grackle (*S. ferrugineus*, Swains.) is about 9 in. long, extent of wings 14 in., bill 1 in., tarsus  $1\frac{1}{2}$ ; the plumage is soft and glossy, of a deep black color, with greenish and bluish reflections; the female is smaller, of a general brownish or rusty black, the feathers beneath margined with brownish; the young resemble the female, with the head, neck, and lower parts lighter brown, and the rump tinged with gray; in the autumn and winter even the males become rather rusty. They are found from the Atlantic coast to the Missouri, migrating to the far north in the spring to breed; in the autumn they return to the south in small flocks with the cow-bunting and red-winged blackbird, with which they associate until spring returns. The flight is quick and undulating, and the walk is graceful, the tail being jerked up and down at every step. They frequent the corn fields and rice plantations, where they do little mischief; they are fond of the com-

pany of cattle, picking out the grain from their droppings; in the winter they resort to marshes and watercourses, feeding on aquatic insects and small mollusks. Their note is a kind of chuck, but during the breeding season they are noisy and have a lively and agreeable song. They are not very shy. The nest is built on low bushes in moist places, of coarse materials, and the eggs, four or five, are light blue, streaked and dashed with lines of brown and deep black. The Mexican grackle (*S. cyanocephalus*, Cab.) is a somewhat larger bird, with a stouter bill, and a purplish gloss confined to the head and neck; it is found from Minnesota to the Pacific, and as far south as Mexico.—The other grackles belong principally to the genus *quiscalus*, characterized by a bill as long as the head, broad, with the edges inflexed, and the tip of the upper mandible overhanging the under; the wings moderate, the second, third, and fourth quills the longest; the tail longer than the wings, graduated and the sides turned upward; the tarsi as long as the middle toe, strong, and greatly scutellated; the toes strong, and the hind one long, all scutellated; claws short, robust, and slightly curved. More than 12 species are described, which migrate according to the seasons; in winter their immense flocks are very destructive on plantations, while in spring they devour from the fields and ploughed lands great numbers of worms, grubs, and caterpillars, injurious to vegetation; they pull the young corn soon after it has sprouted, and also attack it when in the milky state. The species found in the United States are best distinguished by the size and form of the tail. The largest is the great-tailed grackle (*Q. macrourus*, Swains.), 18 in. long, with an extent of wing of about 27, and the tail  $9\frac{1}{2}$ ; the color is shining black, with purple and green reflections, and the feathers of the head soft and velvety; it is found from the valley of the Rio Grande in Texas southward. The boat-tailed grackle, great crow-blackbird, or jackdaw as it is sometimes called (*Q. major*, Vieill.), is about 16 in. long, with an extent of wings of 2 ft.; the color is shining black, the purple gloss being confined to the head, neck, and fore part of the breast, elsewhere with green reflections; the crown feathers are coarse and stiff. Their habits are the same as those of the other grackles; they seek their food among the salt marshes and along the muddy shores, eating fiddler crabs, insects, worms, shrimps, and other aquatic animals; they are fond of the eggs of other birds, and commit depredations in the corn and rice fields. They are very shy, and fly at a considerable elevation and for long distances; the notes are harsh and shrill, though rather pleasing in the love season. The nest is large, of coarse materials, placed on tall reeds growing in the water, on smilax bushes, and on live oaks, where they breed in communities; they begin to lay about the 1st of April, sometimes earlier; the eggs, four or five, are dull white with irregular streaks of brown and black; only one

brood is raised in a season. This species is found in the southern Atlantic and gulf states, near the coast, and in Texas. During the breeding season, the sides of the tail are turned upward, whence its common name has been

Purple Grackle (*Quiscalus versicolor*). 1. Female. 2. Male.

derived. The purple grackle, or common crow-blackbird (*Q. versicolor*, Vieill.), is 13 in. long, with an extent of wings of 19; the head and neck are steel-blue, the rest of the plumage with varied reflections of bronze, golden, green, violet, and copper; the female is smaller, with a less brilliant and more brownish plumage. The habits are the same as in the others of the genus; the friends of the farmer in spring by devouring grubs, in summer and early autumn they dispute the possession of the corn fields with the planters, who seek to frighten or destroy them; their mischief is so great that the corn is sometimes steeped in saline and bitter solutions to prevent it from being pulled up; in cold weather they feed upon beech nuts, acorns, and the refuse of the cattle pens. In the southern states the nest is generally in a hole in a decayed tree; the eggs, four to six, are bluish, with brown and black streaks and blotches; in the north, pine trees are favorite places for their nests. They are found in the Atlantic states, from New England to Florida, and on the high central plains of the continent. The flesh is eatable.—The genus *scaphidurus* has a long bill, with the culmen advancing on the forehead, and sloping to an acute and curved tip; the wings are long and pointed, the first quill the longest; the tail lengthened, graduated, with the sides turned upward. They are found in the West Indies and in South America.

**GRAMMAR.** See LANGUAGE.

**GRAMME**, the French unit of weight, equal to 15.4325 grains troy, or very nearly  $\frac{1}{16}$  of a dram avoirdupois. It is the weight of a cubic centimetre of distilled water at the temperature of maximum density, 4° C., or 39.2° F.

The gramme is divided, according to the French system, into 10 decigrammes, 100 centigrammes, or 1,000 milligrammes. Its multiples by 10 are successively deca-, hecto-, kilo-, and myriagrammes. The weight of the kilogramme, or 1,000 grammes, is equal to 2.6793 lbs. troy, or 2.2046 lbs. avoirdupois. In rough estimates 50 kilogrammes are often conveniently taken as equivalent to 1 cwt., being only  $\frac{1}{4}$  lb. short of this, and 1,000 kilogrammes as 1 ton, the deficiency being only 35.4 lbs.

**GRAMONT**, an ancient French family, which traces its origin to the 14th century, takes its name from the seignorial estate of Gramont in Lower Navarre, and has produced several distinguished men. **I. Antoine III.**, duke de, distinguished himself in several campaigns during the reigns of Louis XIII. and Louis XIV., became marshal of France in 1641, was commissioned in 1660 to bring from Spain the infanta Maria Theresa as bride of Louis XIV., and died in 1678. He left personal *Mémoires*, which were published by one of his sons. **II. Philibert**, count de, brother of the preceding, born in 1621, died Jan. 10, 1707. His innumerable love affairs, gambling adventures, and intrigues have been handed down to posterity in the sprightly narrative by his brother-in-law, Anthony Hamilton. This hero of fashionable licentiousness, after figuring indifferently in several campaigns, was ordered to leave France in 1662, because he had been presumptuous enough to pay his homage to Mlle. Lamothe Houdancourt, upon whom Louis XIV. had fixed his affections. He then repaired to the court of Charles II. of England, where he became the favorite of many ladies of rank and beauty. He was stopped at last in his career of debauchery by an enforced marriage with Eliza Hamilton. He returned to France with his wife, who was appointed lady in the household of Queen Maria Theresa. He was 80 years old when, to divert him, his brother-in-law undertook the *Mémoires* which were to perpetuate his name. **III. Antoine Agénor Alfred**, duke de, a French diplomatist, born in Paris, Aug. 14, 1819. He commenced his diplomatic career in 1852, and represented France successively at Cassel, Stuttgart, Turin, and Rome. He was sent to Vienna in 1861, and held the post of ambassador there until in May, 1870, he entered the Ollivier cabinet as minister of foreign affairs. When Prince Leopold of Hohenzollern spontaneously renounced his candidacy for the Spanish crown, Gramont further insisted that the king of Prussia should give a solemn promise that no prince of his house should in future be a candidate for the throne of Spain. On July 15 Gramont officially announced to the French chambers that war existed between France and Prussia. When the Ollivier ministry were compelled to resign, Aug. 9, 1870, Gramont retired to private life. During and since the war he has been the object of vehement attacks in the French journals. In January, 1872, he was

summoned, with Marshal Lebœuf, to appear before a committee of inquiry into the causes of the revolution of Sept. 4, 1870.

**GRAMPIANS**, a range of mountains traversing Scotland diagonally from S. W. to N. E. for 150 m., and forming the natural boundary between the highlands and the lowlands. Beginning in Argyleshire, on the W. coast, near the S. W. extremity of Loch Awe, they pass along the W. and N. boundaries of Perthshire, including the Ben Lomond hills in Stirlingshire to the south, and at Cairn Ealer divide into two branches, which pass to the sea respectively on the N. and S. sides of the river Dee. The term is not strictly limited in its application, but in its widest usage it includes all the highest mountains of Scotland. Several of its summits, as Ben Nevis, Ben Macdhui, Cairntoul, and Cairngorm, rise to a height of about 4,000 ft.

**GRAMPUS**, a porpoise-like cetacean, belonging to the genus *phocæna* (Cuvier); English writers, however, make a generic name of the word grampus, calling the animal *G. orca* (Fabr.). The name seems to be a corruption of the French *grand poisson* (large fish), to which its size well entitles it. Other names are finner and black-fish whale, from its dorsal fin and prevailing color; killer or thrasher, from its alleged habit of attacking and killing the whale. It attains a length of 25 to 30 ft., with a circumference of 10 or 12; the snout is short and rounded, the lower jaw broader and shorter than the upper; the teeth are about 44, 22 above and 22 below, large, strong, conical, and somewhat hooked; the so-called dorsal fin, near the middle of the back, is 4 ft. high, and the pectorals are large and oval; the tail is lunate, thick, and powerful. The color is black above, suddenly changing to white on the sides and beneath; a large white patch behind and above the eyes. It is occasionally

cious and entirely carnivorous, devouring large fish, such as cod, halibut, skates, turbot, &c., smaller cetaceans, and even seals. American whalers call it killer and thrasher, and affirm that a herd of them will surround a large whale, bite and tear away its flesh with their powerful teeth, and finally weary and destroy it; the accounts of such cetacean combats are probably exaggerated, but from the size, strength, and voracious habits of the grampus, no doubt even whales sometimes fall victims to their hungry herds. The oil, though small in quantity, is of excellent quality. Gray, in the *Spicilegium Zoologicum*, vol. ii., describes other species, as *G. intermedius*, *Heavisidii*, and *obscurus*, the last two from the Cape of Good Hope; all the species are frequently called dolphins, though they have not the prolonged beak of the latter.

**GRAN** (Hung. *Esztergom*). **I.** A N. W. county of Hungary, traversed from W. to E. by the Danube; area, 424 sq. m.; pop. in 1870, 65,306, mostly Magyars. The surface toward the centre is flat, in the north generally level, and mountainous in the south. The river Gran (Hung. *Garam*), which rises in the Carpathians, traverses the N. E. portion of the county. The soil, which is generally fertile, produces corn, fruits, and wine, of which the Neszmélyi is favorably known in commerce. Coal, limestone, and gray, red, and variegated marble are found. **II.** A city, capital of the county, on the right bank of the Danube, crossed here by a bridge, opposite the mouth of the Gran, 24 m. N. N. W. of Pesth; pop. in 1870, 8,780. It is a royal free city, the seat of an archbishop, primate of Hungary, who was made cardinal in 1874, and contains many remarkable buildings, the most conspicuous of which are the palace of the primate, the houses of the chapter, and the cathedral, in the Italian style, one of the finest churches of Europe, built on a precipitous height overlooking the Danube. It has also a gymnasium and a theological seminary. The inhabitants are chiefly employed in the manufacture of woollen cloth. Gran is said to have been founded by the Romans. It continued to flourish until it was destroyed by the Tartars, on their invasion of Hungary, 1241-'3. At a later period it was taken by the Turks, and reconquered in 1683 by John Sobieski.

**GRANADA**. **I.** A W. department of Nicaragua, between Lake Nicaragua and Lake Managua, and bordering on the Pacific; area, 2,943 sq. m.; pop. about 56,000. The general aspect of this department is that of an extensive table land, with a gentle descent toward the lakes and steep acclivities on the side of the Pacific. A low central chain of mountains divides the country into almost equal portions, the northern and western being essentially volcanic, though cultivated in every direction and densely populated, in spite of the great scarcity of water. Among the numerous volcanoes are Mombacho, Masaya, Madera, and

Grampus (*Grampus orca*).

seen on our coast, and not unfrequently on the shores of Europe and in the middle Atlantic; its favorite haunts are the northern regions, in the vicinity of Greenland and Spitzbergen. They are often met in small herds of six or eight, chasing each other as if in sport; they are swift and strong, which renders their capture difficult, and they yield comparatively little oil. The grampus is exceedingly vora-

Ometepe, on the beautiful island of Zapatera, in Lake Nicaragua. A few of the volcanoes are still active, but the most recent serious eruption was that of Masaya in 1858. Besides the two large lakes, there are several small ones having no visible outlet. There are no navigable rivers. The mineral productions are abundant, and many mineral springs exist. **II.** A city, capital of the department, on the W. shore of Lake Nicaragua, 27 m. S. E. of Managua; pop. about 10,000. The streets are irregular and unpaved. There are three ancient churches. On the lake side stand the remains of the old fortifications of the city. A company was formed in 1872 for raising the water of the lake to the city by machinery, the elevation being 58 ft. The hospital is in a dilapidated condition, and one wing is used as a prison for females. The university courses are held in the halls of the ancient cloister of San Francisco. The situation of Granada is unequalled in a commercial point of view by any other inland town in Central America, but its trade is at a low ebb, although the products of several departments concentrate here for shipment by the lake steamers, which leave twice or thrice a month, and reach the Atlantic through the Rio San Juan. The town was founded in 1523, and was in the latter part of the 17th century repeatedly plundered and partially destroyed by buccaneers. The usurper Chamorro having taken refuge here, the democrats besieged the city from May, 1854, to February, 1855. After the death of Chamorro, in 1855, the filibuster William Walker took the city by surprise, burned it, and established a provisional government which lasted till 1857, when Granada was retaken by the united arms of San Salvador and Guatemala. A large portion of the city has been rebuilt since that time; but whole squares still lie in ruin, covered with vegetation.

**GRANADA. I.** An ancient kingdom of Spain, in Andalusia, now comprising the three modern provinces of Malaga, Granada, and Almeria, bounded S. and E. by the Mediterranean; greatest length about 200 m., greatest breadth about 80 m.; area, 11,063 sq. m. The surface is diversified, with lofty mountains, beautiful valleys, and extensive plains. The Sierra Nevada mountains traverse the territory from E. to W.; their summits are crowned with perpetual snow, and one of them, the Cerro de Mulhacen, attains an elevation of 11,654 ft. above the sea, and is the highest mountain in Spain. The only railway of the province connects the city of Granada with Antequera and the railway from Malaga to Cordova. The principal rivers are the Jenil, the Almanzora, and the Guadalorze. The climate of the mountain districts is cold, that of the plains temperate, and that of the valleys sultry and unhealthy, especially during the prevalence of the wind called *solano*, which blows periodically from the Mediterranean. The soil is barren or fertile in proportion to the possibil-

ity of irrigating it from the mountain streams. Agriculture is the chief business. The principal manufacture is silk. The wine is generally inferior, but the *tierno*, muscatel, and Malaga are exceptions, and have a high reputation. The sugar cane grown in the neighborhood of Velez Malaga is deemed fully equal to that of the West Indies for size and juiciness. The foreign trade is not important, and is chiefly carried on through the ports of Almeria and Malaga. This province formed an opulent, civilized, and powerful kingdom under a Moorish dynasty founded in 1238, which was overthrown by Ferdinand the Catholic in 1492.

**II.** A modern province, bounded N. by Cordova, Jaen, and Albaete, E. and S. by Almeria and the Mediterranean, S. W. by Malaga, and N. W. by Cordova; area, 4,937 sq. m.; pop. in 1870 estimated at 485,000. It is almost entirely mountainous, the only large tract of level country within its boundaries being the Vega or plain of Granada, on the Jenil, between the capital and Loja. **III.** A city, the capital of the province and kingdom, on two declivities of the Sierra Nevada and on the plain between them, 34 m. from the Mediterranean, and 224 m. S. of Madrid; lat. 37° 13' N., lon. 3° 40' W.; pop. about 68,000. The river Darro flows through it, and falls into the Jenil just outside the walls. The site of the city is about 2,000 ft. above the sea, and its appearance from a distance is singularly picturesque and beautiful. It is divided into the city proper, the Alhambra suburb, the Albaycin suburb, and the Antequeruela suburb. The first three are partially fortified, but the fourth is entirely open, and here the working classes generally reside. The streets are narrow and crooked, but the houses are well built in antique oriental style. There are several handsome squares and numerous public fountains. But the public edifices and the monuments of its former splendor are the great attractions of Granada, and first among these must be ranked the Alhambra, or ancient palace of the Moorish kings. (See ALHAMBRA.) The Gothic cathedral is profusely ornamented with jasper and colored marble, and surmounted with a dome resting on 12 arches, beneath which stands the gorgeously decorated altar. The church of Nuestra Señora de las Angustias is remarkable for its altar and towers; the church of San José, a modern structure, for its elegance. The monastery of San Gerónimo contains the tomb of its founder, Gonsalvo de Cordova; but his bones were dug up and cast out by a mob who plundered the convent in 1836. Granada contains the unfinished palace of Charles V., the Generalife, a Moorish palace surrounded with gardens and fountains, an episcopal palace, a university, and a general hospital, as well as many conventual establishments for both sexes. The chief manufactures are silk, woollen stuffs, hats, paper, saltpetre, and gunpowder. The trade is insignificant, and the roads leading to the city are so wretch-

ed that in the rainy season they are almost impassable. Granada was founded by the Moors in the 10th century, and from 1238 was the capital of the kingdom of Granada till its sub-

version in 1492, when it was taken by Ferdinand and Isabella after a protracted siege. It prospered for another century, but when the Moors, who composed the greater part of

Granada.

its population, were finally expelled from Spain in 1609, it received a blow from which it has never recovered. At the height of its splendor it is said to have contained as many as 500,000 inhabitants.

**GRANADA, New.** See COLOMBIA.

**GRANADILLA** (Span., diminutive of *granada*, a pomegranate), the Spanish-American name for the edible fruit of several species of *passiflora*, especially that of *P. quadrangularis*. The genus *passiflora*, which will be described under PASSION FLOWER, is well known for the great beauty of the flowers of many species which are common greenhouse climbers. Other edible-fruited species are *P. edulis*, *P. laurifolia* (the water lemon), *P. maliformis* (the sweet calabash), and *P. incarnata*, the may-pop of the southern states. *P. quadrangularis* is a native of the West Indies, where its fruit is esteemed for the dessert. In French works upon horticulture it is placed among the exotic fruits to be grown under glass, and granadillas thus produced are sometimes seen in the markets of Paris and London. In our greenhouses the plant is often seen in flower, but rarely in fruit, as gardeners do not seem to be aware that the flowers require to be artificially fertilized with their own pollen or that of some other species, else the fruit will not set. The fruit is 6 or 8 in. in diameter, of a mulberry color, and with an odor something like the pineapple or strawberry. The purple pulp, which encloses numerous seeds, is subacid, and is usually eaten with wine and sugar. In contrast with the fruit, the root of this species is powerfully narcotic and emetic.

**GRANBY, John Manners**, commonly called marquis of, an English general, born Jan. 2, 1721, died in Scarborough, Oct. 19, 1770. He was the eldest son of the third duke of Rutland, was educated at Eton and Cambridge, and during the rebellion of 1745 raised a regiment of foot at his own expense. In 1759 he was sent to Germany as second in command, under Lord George Sackville, of the troops destined to co-operate with Prussia. Lord George having resigned, Granby succeeded to the chief command of the British, and served with distinction during the remainder of the seven years' war. In 1760, while still in the field, he was appointed a member of the privy council. In 1763 he became master general of the ordnance, and in 1766 commander-in-chief of the forces. He also served several terms in parliament. He was exceedingly popular, but his military qualities appear to have been greatly overrated.

**GRAND**, the N. W. county of Colorado. See SUMMIT.

**GRANDEE** (Span. *grande de España*), the highest rank of Spanish nobility. The grandes of Spain were the great nobles descended from the ancient chief feudatories of the crown, and from members of the royal family. They had the right to levy soldiers under their own banner, were free from taxes, and could not be subjected to the jurisdiction of any civil or criminal court without the express command of the king. They also claimed the right to make war upon the king without incurring the guilt of treason. As the power of the monarch increased, the privileges of the grandes were restricted, till little was left but the right

of wearing their hats in the royal presence, and of being saluted by the guards at the royal palace. The Spanish grandees considered themselves superior in rank to all the other nobility of Europe, and second only to princes of royal blood. On public occasions the order of precedence placed them next to the high prelates. Many of the grandees had no title; others had the titles of count, marquis, and duke, and some possessed enormous estates. Among the richest were the dukes of Medina Celi, Alva, Ossuna, Altamira, Infantado, and Arcos. The duke of Arcos, in the latter part of the 18th century, maintained 3,000 servants. The grandees have no privileges now.

**GRAND FORKS**, a N. E. county of Dakota territory, recently formed, and not included in the census of 1870; area, about 4,000 sq. m. It is separated on the east from Minnesota by the Red river, and is drained by several affluents of that stream.

**GRAND HAVEN**, a city, port of entry, and the capital of Ottawa co., Michigan, at the mouth of Grand river, on the E. shore of Lake Michigan, opposite Milwaukee, and 90 m. W. N. W. of Lansing; pop. in 1870, 3,147. It is bounded on two sides by hills, and in the neighborhood are extensive peach orchards. Springs possessing medicinal properties have lately been discovered. The city contains one of the finest hotels in the state, a cemetery of 40 acres, and three school houses. It is the W. terminus of the Detroit and Milwaukee railroad, and is intersected by the Michigan Lake Shore line. Steamers run throughout the year to Milwaukee, and in summer a daily line plies to Grand Rapids. The principal manufactories are seven saw mills, a shingle mill, a machine shop, two ship yards, and one manufactory each of agricultural implements and furniture, of sash, doors, and blinds, of spinning wheels, and of curtain rollers. There are a dry dock, a national bank, two weekly newspapers, a high school, and 11 churches. Grand Haven was laid out in 1836, though a trading post had been established on its site by the northwestern fur company in 1825. It received a city charter in 1867.

**GRAND ISLE**, a N. W. county of Vermont, consisting of a number of islands in Lake Champlain and the S. part of a peninsula jutting into the lake from Canada between Richelieu or St. John's river and Missisquoi bay; area, about 77 sq. m.; pop. in 1870, 4,082. The chief islands are North Hero, South Hero, and Isle La Motte. The surface is undulating, and the soil fertile. The county is famous for its orchards, which yield the finest apples in the state. The chief productions in 1870 were 21,073 bushels of Indian corn, 105,431 of oats, 26,876 of buckwheat, 26,295 of peas and beans, 51,599 of potatoes, 160,653 lbs. of butter, 83,838 of wool, 12,271 tons of hay, and 15,982 lbs. of hops. There were 1,285 horses, 2,827 cattle, and 16,087 sheep. The lake is here navigable by vessels of 90 tons. The Vermont

Central railroad crosses the N. part of the county. Capital, North Hero.

**GRAND MANAN**, or *Menan*, an island off the E. coast of Maine, at the entrance to the bay of Fundy, belonging to Charlotte co., New Brunswick; pop. in 1871, 1,867. Its length is nearly 20 m., and its average breadth about 5 m. It abounds with excellent timber, and has several fishing stations. The coast is deeply indented, and affords numerous good harbors. There is a lighthouse on the island, lat. 44° 45' 52" N., lon. 66° 44' 4" W.

**GRANDPRÉ**, *Louis Marie Joseph Ohier*, count de, a French navigator and traveller, born in St. Malo, May 7, 1761, died in Paris, Jan. 7, 1846. After a long experience on the sea as a trader, he entered the navy, and at the end of 15 years' service was admitted to the *hôtel des invalides*, where he remained until his death. He published *Voyage à la côte occidentale d'Afrique, fait dans les années 1786 et 1787* (2 vols. 8vo, 1801), in which he gives an interesting account from his own observation of the Congo slave trade before the French revolution; *Voyage dans l'Inde et au Bengale fait dans les années 1789 et 1790* (1801), followed by *Voyage dans la mer Rouge*. He also published a *Dictionnaire universel de géographie maritime* (2 vols. 4to, 1803), an *Abrégé élémentaire de géographie physique* (8vo, 1825), a *Répertoire polyglotte de la marine* (2 vols. 8vo, 1829), and many essays, among them a *Mémoire sur l'emplacement que l'île Atlantide peut avoir occupé entre l'ancien et le nouveau monde*.

**GRAND RAPIDS**, a city and the capital of Kent co., Michigan, situated at the rapids of Grand river, here spanned by five bridges, 30 m. E. of Lake Michigan and 60 m. W. N. W. of Lansing; pop. in 1850, 2,686; in 1860, 8,085; in 1870, 16,507, of whom 5,725 were foreigners. It is built on both sides of the river, which here, deviating from its general W. direction, runs nearly S. between high bluffs about a mile apart, which gradually diverge and nearly disappear above and below the city. The central school building, erected in 1868 at a cost of \$50,000, is on the highest part of the bluffs E. of the river, and commands a fine view. The county jail, built in 1872, is a fine specimen of architecture. There are many handsome residences, a number of gravelled streets, and several miles of street railroad. The river is navigable to this point for steamers of considerable size. Six railroads intersect here: the Detroit and Milwaukee, the Grand Rapids and Indiana, the Grand River Valley division of the Michigan Central, the Kalamazoo division of the Michigan Southern, the Chicago and Michigan Lake Shore, and the Grand Rapids, Newaygo, and Lake Shore. The rapids furnish extensive water power, which is utilized by means of two canals. The one on the E. side of the river is 2,600 ft. long, 140 ft. wide at the upper and 30 ft. at the lower end; the W. side canal is 3,300 ft. long, 100 ft. wide at the upper and 50 ft. at

the lower end. Only a portion of the available power is in actual use. The principal manufactures are of wood work, embracing furniture, barrels, and rim and bent work, tubs, pails, sashes and blinds, carriages and wagons, &c. There are also manufactories of agricultural implements and brushes, several foundries and machine shops, chemical works, tanneries, breweries, &c. The pine lumber produced in 1872 exceeded 60,000,000 ft. A large establishment for preserving fruit has recently been erected. Four firms, with an aggregate capital of \$400,000, are engaged in quarrying and manufacturing gypsum, which is abundant in the vicinity, the annual production being about 100,000 tons. Cream-colored bricks, known as Milwaukee bricks, are also manufactured here. There are two national banks with an aggregate capital of \$700,000, and a savings bank. The city is divided into eight wards, is lighted with gas, and has an efficient police force and a paid fire department. The assessed value of property in 1873 was \$4,949,282. The United States circuit and district courts for the W. district of Michigan are held here. The school buildings are nine in number, including a high school. There is a public library with more than 7,000 volumes, a free reading room, and a scientific institute which has a fine museum. There are three daily and five weekly (one Dutch and one German) newspapers, two monthly periodicals, and 20 churches. Grand Rapids was first settled in 1833, and incorporated in 1850.

**GRAND RIVER** (Ind. name, *Washtenong*), a river of Michigan, and the largest which lies wholly in that state. It rises in the S. E. part of the lower peninsula, in two branches which unite near Jackson, and after a N. W. and W. course of about 270 m., including its numerous windings, it discharges into Lake Michigan at Grand Haven. It is about 950 ft. wide at its mouth, and deep enough for vessels of less than 12 ft. draught. Steamboats ascend 40 m. to the rapids, where the river has a fall of 18 ft. in a mile; and small boats ply between the head of the rapids and Lyons, about 50 m. further. The principal affluents are the Rogue, Flat, Maple, Looking-glass, and Red Cedar from the north, and the Thornapple from the south. Jackson, Lansing, Grand Rapids, and Grand Haven are the chief towns on its banks.

**GRAND RIVER**, one of the constituents of the Colorado of the West, rises in the Rocky mountains in Colorado territory, 5 or 6 m. W. of Long's peak, in about lat. 40° 17' N., lon. 105° 43' W. It pursues a general S. W. course of about 350 m., and joins the Green in Utah territory. It bends S. just before entering Utah, and then N. as it crosses the boundary, resuming its general direction. The only important tributary from the north is Milk creek, which joins the main stream near its source. From the south it receives the Blue river (which, rising near the base of Mt. Lincoln, has by some been regarded as the true source of the Grand), Piney creek,

Roaring fork, the Gunnison or South fork (the largest tributary), and the San Miguel and Dolores rivers, which unite and empty into the Grand just beyond the Utah border. It flows through a mountainous region, forming deep and precipitous cañons.

**GRAND TRAVERSE**, a N. W. county of the S. peninsula of Michigan, bounded N. E. by Grand Traverse bay; area, about 500 sq. m.; pop. in 1870, 4,443. It is drained by Grand Traverse river, which enters the bay of the same name. The surface is undulating and dotted over with a great number of small lakes. The chief productions in 1870 were 31,157 bushels of wheat, 26,708 of Indian corn, 15,218 of oats, 94,174 of potatoes, and 3,544 tons of hay. There were 2 flour and 9 saw mills. Capital, Grand Traverse City.

**GRANDVILLE**, Jean Ignace Isidore, whose real name was GÉRARD, a French caricaturist, born in Nancy in September, 1803, died at Vanves, near Paris, in March, 1847. He was the son of a miniature painter, and attracted attention in 1828 by his *Métamorphoses du jour*, illustrating prevailing follies and vices by representing well known personages with the faces of animals. His political caricatures and his pictures of animals increased his reputation, and he furnished many designs for illustrated and humorous journals, for Lafontaine's fables, and for many other works. In the latter part of his life he took up fantastic and ghostly subjects, and he died in a lunatic asylum.—See *Grandville*, by Charles Blanc (Paris, 1855).

**GRANE**, Gran, or Quade (Arabic, *El-Kueit*), a seaport town of Arabia, in the district of El-Hasa or Ahsa, on a bay of the same name, at the N. W. corner of the Persian gulf, 90 m. S. of Bassorah; lat. 29° 23' N., lon. 47° 57' E.; pop. about 9,000. It is on a peninsula jutting into the bay, which is 60 m. in circuit, affords excellent anchorage for the largest vessels, and is well protected by the small island of Felej or Felitche. In the town there is a scarcity of water. Most of the houses are built of clay, but many wealthy merchants reside here. Trade is carried on with the Red sea and India.

**GRANGE**, National. See HUSBANDRY, PATRONS OF, and supplement.

**GRANGER**, Gideon, an American statesman, born at Suffield, Conn., July 19, 1767, died at Canandaigua, N. Y., Dec. 31, 1822. He graduated at Yale college in 1787, and rose to eminence at the bar. In 1801 President Jefferson appointed him postmaster general. He was reappointed by President Madison, but was displaced in 1814 for opposing Madison's policy. He then removed to Canandaigua, N. Y. He gave 1,000 acres of land to further the construction of the Erie canal.—His son FRANCIS, born Dec. 1, 1792, was also a prominent lawyer and member of congress, and postmaster general from March to July, 1841. He died at Canandaigua, N. Y., Aug. 28, 1868.

**GRANICUS** (now *Khodja Tehai*), in ancient geography, a small river of Asia Minor, rising

N. W. of Mt. Ida, and emptying into the Propontis after a N. E. course of 50 or 60 m. It is famous as the scene of the first decisive victory of Alexander the Great over the Persians, 334 B. C.

**GRANIER, Adolphe Bernard**, commonly called A. GRANIER DE CASSAGNAC, a French journalist, born in the department of Gers about 1806. He was educated at the college of Toulouse, and began his career at Paris in 1832, by writing literary criticisms for the *Journal des Débats* and the *Revue de Paris*. The asperity of his articles displeased Bertin, editor of the *Débats*, and Granier joined the *Presse*, then just founded by Girardin. In this journal he defended Victor Hugo and the romantic school, and wrote severe criticisms upon Racine. A collection of these articles was published in 1852 under the title of *Portraits littéraires*. In 1837 he published *Histoire des classes ouvrières et des classes bourgeoises*, and in 1840 *Histoire des classes nobles et des classes anoblies*. He also wrote pamphlets in defence of slavery, by which he recommended himself to the planters of Martinique and Guadeloupe; and in 1840 he made a visit to the West Indies, of which an account was given in his *Voyage aux Antilles* (2 vols., 1842-'4). While there he married Mlle. Beauvallon, a creole. On his return to Paris he became editor of the *Globe*. His conduct of this journal involved him in various controversies and duels. In 1845 his brother-in-law Beauvallon, who was employed upon the same paper, killed Dujarrier, the manager of the *Presse*, in a duel, and was prosecuted for having used unfair means. He was acquitted, but was afterward convicted of having procured his acquittal with false witnesses. Granier de Cassagnac testified on these trials in behalf of his brother-in-law, and his character was compromised by their result. The *Globe* having been discontinued in 1845, he founded an ultra-conservative journal called *L'Époque*, which existed for two years. He was then sent by Guizot to found a journal at Rome for the promotion of French interests. On the breaking out of the revolution of 1848 he returned to France, but did not go to Paris till 1850. He was a declared opponent of the republic and a devoted adherent of Louis Napoleon. He became in 1850 the principal editor of the *Pouvoir*, then a regular contributor to the *Constitutionnel*, and in 1857 founded the *Réveil*. This survived but a year, and he then assumed the direction of the *Pays*. The next paper which he edited was *L'Écho*, which in 1863 was merged in the *Nation*. In 1866 he resumed the direction of the *Pays*. He was four times elected to the chamber of deputies, as a government candidate, 1852-'69. In the chamber he was a violent partisan of the government. In 1868 he voted with six of his colleagues against a law which was favorable to the press, and replied to arguments advanced by Picard and Ollivier in relation to it with a challenge to fight. Both he and his son, Paul de Cassagnac, be-

came notorious for the great number of controversies, duels, and broils in which they were engaged. After the French reverses in the war of 1870-'71 he resided partly at Wilhelms-höhe and partly at Brussels. After the restoration of peace he returned to Paris and wrote occasionally for the *Pays*. In 1873 he published *Histoire des origines de la langue française*, in which he contended, as he had done in the *Presse* in 1836 and in his *Antiquité des patois: antériorité de la langue française sur le latin* (1859), that the French was spoken in Gaul before Latin was introduced. He has also published *Histoire des causes de la révolution française* (1850; 2d ed., 3 vols., 1856); *Histoire du directoire* (3 vols., 1851-'6); *Histoire de la chute du roi Louis Philippe, de la république de 1848 et du rétablissement de l'empire* (2 vols., 1857); *Histoire des Girondins et des massacres de septembre* (2 vols., 1860); and *L'Empereur et la démocratie moderne* (1861).

**GRANITE**, a hard firm rock, made up essentially of crystalline grains of feldspar and quartz, deriving its name from its granular structure. The typical granites are generally described as composed of a potash feldspar (orthoclase), quartz, and mica; but there are similar rocks which entirely lack the mica, and others in which it is replaced by hornblende. To this latter combination some writers give the name of syenite, but this term appears to have been originally employed to designate a rock composed of hornblende with a soda feldspar (albite, oligoclase, or labradorite), and without quartz, being identical with what by other authors is called diorite. It seems better therefore to follow the example of certain German lithologists, who define granite as a binary aggregate of orthoclase feldspar and quartz, in which mica and hornblende may be present as accidental minerals, giving rise to micaceous and hornblende granite, while the variety from which they are both absent is termed normal or binary granite. In some cases a chloritic mineral, often confounded with talc, takes the place of mica, and gives rise to what has been called protogine or talcose granite. The color of the feldspar of granite is generally white, gray, or reddish, while the quartz is either colorless or somewhat smoky, the hornblende greenish black, and the mica varies in color from nearly white to brownish or blackish. Associated with the orthoclase, some granites contain portions of a soda feldspar, which may be either albite or oligoclase, distinguished from the former by its white or greenish-white color, which often contrasts with the reddish tint of the orthoclase. There are various degrees of fineness in the texture of granites, and some of them, which have large crystals of orthoclase imbedded in a finely granular mixture of the constituent minerals, are called porphyritic granites. Geologically granite is described as an unstratified rock, from the fact that it wants the banded or stratified structure which characterizes gneiss, a

granular rock made up of the same mineral species arranged in layers, which are generally supposed to represent planes of deposition. Moreover, granite appears in irregular masses, breaking through gneiss and various crystalline stratified rocks, and often sending out veins or dikes into the midst of these. All the relations of the true granites to the stratified rocks are in fact such as to suggest the notion that the former have been extruded in a more or less pasty condition from below the latter. From the microscopic study of the minute cavities often found in the quartz of granites, which are filled with water or saline solutions, Sorby has concluded that this rock must have consolidated at a temperature in some cases approaching a red heat, and under a degree of pressure which implies that it was at that time buried beneath a very great weight of rock. There is a popular notion that granite is the oldest of all rocks, and is in fact the substratum which underlies all others; but this idea rests upon certain misconceptions, and is probably incorrect. It is true that it is found breaking up through the newer crystalline stratified rocks, the primitive slate formations of some geologists; but these are seen to rest upon an older formation composed in great part of highly crystalline gneiss, which, though often granite-like in its aspect, is clearly stratified, and includes beds of quartzite, limestone, and iron ores. This oldest known series, to which the name of Laurentian is given, was by some of the earlier geologists mistaken for the granite which was supposed to underlie the newer series, and it has been suggested with much probability that it is the gneisses of this old series, which in a softened condition have been forced upward among the overlying formations, where they take the form of unstratified granites. The primitive rock, which is supposed to have been before all stratified deposits, is everywhere concealed by these, and from chemical analogies may be supposed to have been very unlike granite. The so-called granites of the Alps are now shown to be stratified rocks of eozoic age, which by great and profound folds have been brought up and made in some cases to overlie the newer strata. (See ALPS.)—The dikes of a fine-grained granite, which appear as offshoots from the great eruptive masses, are not to be confounded with the granite veinstones, which appear to have been formed by a process of gradual deposition from aqueous solution in fissures or cavities in the rocks. Such veins, although often made up in great part of feldspar and quartz with mica, are closely related to the veinstones of quartz and calc spar, which are so often the gangue of metallic ores. They frequently present a banded structure parallel with the walls of the enclosing rock, and are remarkable for containing in many cases large and beautiful crystals, not only of the constituent minerals of granite, but of rarer species. Among the most common of these are garnet, tourmaline,

beryl, topaz, columbite, and cassiterite. The gneisses and mica schists of what has been called the Montalban or White mountain series of the Appalachians are noted for the abundance of these veins, and for the fine minerals which these contain. Some of these granite veins are mined for the mica which they afford, and others for the pure and abundant white orthoclase which is sought for the manufacture of porcelain. These veins are of very various sizes, sometimes 100 feet or more in breadth, and often traverse the enclosing rocks at right angles. A peculiar aggregate is sometimes found in these veins, in which plates and imperfect skeleton crystals of quartz are so scattered through the masses of cleavable orthoclase, that a section across the ends of these plates presents the appearance of written characters or hieroglyphics on a ground of feldspar; hence the name of graphic granite.—Granite is very strong and durable, and resists the atmospheric influences; but in the southern and western parts of the United States and in South America, as also in central France, it is found to be softened and decayed to considerable depths. This softening, which Dolomieu called the *maladie du granit*, and ascribed to the evolution of carbonic acid from the interior of the earth, depends upon a chemical decomposition of the feldspar, which loses its alkali and a part of the silica in a soluble form, leaving a hydrated silicate of alumina, which in its purest form constitutes kaolin or porcelain clay. The feldspars and hornblends of the gneisses undergo a similar change. According to Sterry Hunt, this decomposition is not recent, and is not connected with an evolution of carbonic acid from below, but was effected in remote periods, when the whole atmosphere was highly charged with this gas, and has ceased in modern times; although it is not impossible that some such changes may now be going on in localities where an abundance of carbonic acid is given off from the earth. The red granites from Peterhead, near Aberdeen in Scotland, are especially esteemed for their beauty of color. Similar red granites are found on the coasts of Maine and New Brunswick; and the hornblendic granites of Rockport and Quincy in Massachusetts are quarried in very large quantities and shipped to distant points.—True granite is found in masses of great solidity, unbroken by seams and of remarkably uniform structure. It is seen upon the sides of mountains covering acres, with hardly a crack or seam. But, however massive and unbroken it appears, it exhibits when quarried a tendency to divide more easily in some directions than in others, and is found to be really traversed by parallel seams, which separate it into blocks more or less symmetrical. Having great durability, and being so hard and compact that the finer varieties are susceptible of a good polish, and when carved retain better than any other rock used for architectural purposes the sharp edges of mouldings, granite has always

occupied the first rank among building stones. Its great strength to resist pressure is exhibited in the trial of the Aberdeen granite used in the construction of the piers in the vaults of the London custom house. A half-inch cube of the best stone required to crush it the pressure of 24,556 lbs. It is easily split in large blocks by a very simple process. With a hand drill and hammer a workman bores a succession of holes from  $3\frac{1}{2}$  to 6 in. in depth, and 2 to 6 in. apart, along the line where he wishes to open the stone. The depth and number of the holes are proportioned to the size of the block. Into each of the round holes thus made he introduces two slips of iron called half-rounds, buckings, or feathers, being of wedge form, but round on one side, and running to a point. He then inserts a small steel wedge between the flat faces of the two half-rounds and gently tightens it with the hammer. This being done, he moves along the line tapping each wedge in order, and repeating the process till the strain causes a crack, which gradually opens, separating the block. Good granite of close grain and uniform texture should in this way make a clean separation, the crack going straight through twice or three times the depth of the holes. It may even be quarried out of the solid ledge in the same manner, provided there are natural seams; and where practicable the process is much to be preferred to blasting, which wastes the stone, breaking it into irregular fragments. But the latter is necessary in quarrying, to expose suitable faces for splitting, and to open seams. Blocks of great size may be obtained from good quarries, much larger indeed than there is any demand for. They are often split out from 40 to 80 ft. in length, and are afterward reduced to smaller sizes. They are sold in the rough blocks commonly by the ton of 14 cubic feet, or if dressed, by the superficial foot of hammered surface. In many parts of the country gneisses of great homogeneousness and with little evidence of stratification are quarried under the name of granite, for which they furnish an excellent substitute. Such is the case with some of the gneisses of the Laurentian in New York, and still more with the fine-grained gray gneisses of the Montalban series in New England and further southward in the Blue Ridge. The so-called granites of Hallowell and Augusta in Maine, and of Concord in New Hampshire, are examples of these granite-like gneisses. They are somewhat more tender than the true granites, but are more easily wrought, and from their beauty of color and texture are greatly esteemed for architectural purposes. A very fine variety of so-called granite is largely quarried on the James river near Richmond, Virginia, but it is not certain whether it is a true granite or one of the gneisses above described.

**GRANSON**, or *Grandson*, a town of Switzerland, in the canton of Vaud, on the lake of Neuchâtel, near its S. W. extremity; pop. about 1,500. It is chiefly memorable for the

victory achieved near it, March 3, 1476, by the Swiss over Charles the Bold of Burgundy. (See **CHARLES THE BOLD**.)

**GRANT**, a word constantly used in deeds of conveyance, and which once had a specific meaning, that now is almost lost. By the rules of the early common law all estates of land of which actual delivery could be made, could be transferred only "by livery (delivery) of seisin (possession);" that is, by open and actual or symbolic (a key for a house, a sword for a field, &c.) transfer of possession from the one party to the other. But there were valuable interests which could not be transferred in this way, as rents, estates in expectancy, reversions and remainders, and generally all mere rights and all incorporeal hereditaments. These could be transferred only by deeds containing the proper words of transfer. Of these, one of the principal was *concedo*, translated by "grant;" and all things which could be transferred only in this way were said "to lie in grant," while all of the first named class of interests and estates were said "to lie in livery." With *concedo* (grant), *do* (give) was always used; and these two words, "give and grant," were said to be the appropriate and peculiar words of a grant. This distinction between livery and grant was once very important; but it is now little more than a part of the obsolete learning of the law. In all deeds of land, or of any interest in land, corporeal or incorporeal, it is customary to say "give and grant." In several of the United States the peculiar meaning and force of the word may be regarded as abrogated by statute; for all deeds of bargain and sale, of lease and release, and all conveyances of the freehold, are declared to be grants. The same broad construction is given to the word by the practice of conveyancers and of courts in other states, and it would probably be found to prevail generally for all practical purposes.

**GRANT**, the name of 11 counties in the United States. **I.** A N. E. county of West Virginia, bordering N. W. on Maryland, crossed by the Alleghany mountains, and watered by the N. and S. branches of the Potomac; area, 500 sq. m.; pop. in 1870, 4,467, of whom 331 were colored. The soil of the valleys is fertile. Iron ore is found. The chief productions in 1870 were 31,631 bushels of wheat, 52,350 of Indian corn, 10,593 of oats, 67,587 lbs. of butter, 20,689 of wool, and 4,787 tons of hay. There were 1,435 horses, 1,739 milch cows, 4,730 other cattle, 7,551 sheep, and 3,116 swine. Capital, Grant Court House. **II.** A N. central parish of Louisiana, bounded E. by Little river and S. W. by Red river; area, about 500 sq. m.; pop. in 1870, 4,517, of whom 2,414 were colored. It is well watered. The surface is level, and the soil productive. Pine timber abounds. The chief productions in 1870 were 58,786 bushels of Indian corn, 9,948 of sweet potatoes, 2,119 of peas and beans, and 4,377 bales of cotton. There were 651 horses, 1,097 milch cows, 1,771 other cattle, and 4,791

swine. Capital, Colfax. **III.** A S. central county of Arkansas, watered by the Saline river; area, about 650 sq. m.; pop. in 1870, 3,943, of whom 339 were colored. The surface is generally level, and the soil fertile. The chief productions in 1870 were 105,664 bushels of Indian corn, 22,147 of sweet potatoes, and 1,145 bales of cotton. There were 748 horses, 1,367 milch cows, 3,303 other cattle, 2,022 sheep, and 8,770 swine. Capital, Sheridan. **IV.** A N. county of Kentucky, drained by Eagle river, an affluent of the Kentucky; area, about 200 sq. m.; pop. in 1870, 9,529, of whom 509 were colored. It occupies a part of the Dry Ridge, which separates the waters of the Licking from those of the Kentucky. The Louisville and Cincinnati short line railroad passes near the N. border. The surface is undulating and well timbered, and the soil is fertile. The chief productions in 1870 were 41,974 bushels of wheat, 20,384 of rye, 611,568 of Indian corn, 31,059 of oats, 17,668 of potatoes, 137,407 lbs. of butter, 164,295 of tobacco, and 1,541 tons of hay. There were 3,790 horses, 2,364 milch cows, 3,960 other cattle, 7,233 sheep, and 19,563 swine; 4 flour mills, 5 saw mills, and 2 wool-carding and cloth-dressing establishments. Capital, Williamstown. **V.** A central county of Indiana, drained by Mississinewa river; area, 420 sq. m.; pop. in 1870, 18,487. It is intersected by the Pittsburgh, Cincinnati, and St. Louis railroad. It has a level surface and an excellent soil, adapted to grain, grass, and fruit. The chief productions in 1870 were 374,574 bushels of wheat, 540,453 of Indian corn, 68,349 of oats, 41,657 of potatoes, 375,244 lbs. of butter, 84,824 of wool, 28,068 bushels of flax seed, and 9,448 tons of hay. There were 6,942 horses, 5,052 milch cows, 6,636 other cattle, 25,290 sheep, and 27,045 swine. The principal manufactories were 12 of carriages, 2 of clothing, 2 of woollen goods, 6 flour, 3 planing, and 32 saw mills. Capital, Marion. **VI.** A S. W. county of Wisconsin, separated from Iowa on the W. and S. W. by the Mississippi river, bounded N. and N. W. by the Wisconsin and S. by Illinois; area, 1,080 sq. m.; pop. in 1870, 37,979. The surface is diversified by valleys, ridges, prairies, and woodlands; the soil, watered by Platte, Grant, Blue, and other rivers, is fertile. Lead and zinc are abundant, and the former metal is found throughout the S. part of the county, which is said to produce more than 6,000,000 lbs. a year. There were 5 mines in operation in 1870. The Milwaukee and St. Paul (Prairie du Chien division) railroad crosses the N. part, and the Mineral Point railroad terminates at Platteville in this county. The chief productions in 1870 were 914,455 bushels of wheat, 1,744,398 of Indian corn, 1,433,020 of oats, 44,316 of barley, 288,017 of potatoes, 17,971 of flax seed, 861,028 lbs. of butter, 75,821 of wool, 44,585 of hops, and 39,244 tons of hay. There were 13,901 horses, 13,312 milch cows, 23,301 other cattle, 24,936 sheep, and

51,254 swine; 18 manufactories of carriages, 9 of barrels and casks, 3 of bricks, 1 of gunpowder, 6 of pig lead, 9 of saddlery and harness, 5 of woollen goods, 5 saw mills, 4 breweries, and 13 flour mills. Capital, Lancaster. **VII.** A central W. county of Minnesota; area, about 625 sq. m.; pop. in 1870, 340. There are a number of small lakes and streams. The surface is level, and the soil fertile. The St. Paul and Pacific railroad crosses the S. W. part. Capital, Grant Court House. **VIII.** A S. W. county of Nebraska, bordering on Kansas, and bounded on the N. E. by the Platte river; area, about 3,000 sq. m.; pop. in 1870, 484. Since then it has been absorbed by other counties. **IX.** A S. E. county of Oregon, bordering on Nevada; area, 21,000 sq. m.; pop. in 1870, 2,251, of whom 940 were Chinese. The N. W. portion is watered by John Day's river, a branch of the Columbia, the E. part by Malheur river, an affluent of the Snake, and in the south are a number of lakes. The Blue mountains cross the N. part. Along the streams is some fertile land, the grazing lands are more extensive, and forests are common, but much of the county consists of barren sage plains and rocky hills. Gold was discovered in this county in 1861, since which time it is estimated that \$10,000,000 have been produced. The chief productions in 1870 were 17,459 bushels of wheat, 23,426 of oats, 22,172 of barley, 13,225 of potatoes, and 1,193 tons of hay. There were 507 horses, 1,384 milch cows, 2,112 other cattle, 1,154 sheep, and 1,248 swine. Capital, Canyon City. **X.** An E. county of Dakota territory, bordering on Minnesota, recently formed, and not included in the census of 1870; area, about 700 sq. m. It is bounded on the N. E. by Big Stone lake, and is drained by affluents of the Minnesota river. **XI.** The S. W. county of New Mexico, bounded S. by Mexico and W. by Arizona; area, about 10,000 sq. m.; pop. in 1870, 1,143. The Gila river and its tributaries drain the N. and W. portions, while the Rio de los Mimbres flows through the E. part. The Sierra Madre range occupies a portion of the county. The soil in parts is fertile. Copper and gold are found, and there are three quartz mills and a saw mill. Capital, Pinos Altos.

**GRANT, Anne**, better known as Mrs. Grant of Laggan, a Scottish authoress, born in Glasgow, Feb. 21, 1755, died in Edinburgh, Nov. 7, 1838. Her father, Duncan McVicar, an officer in the British army, was ordered to America while she was a child. He received a grant of land in Vermont, and added to it by purchase. Ill health obliged him to return to Scotland in 1768, and his lands were confiscated on the breaking out of the revolutionary war. In 1779 Anne married the Rev. James Grant of Laggan, Inverness-shire, and had a large number of children. On his death in 1801 she was left in straitened circumstances, and in 1803 published a volume of poetry, which met with immediate favor. She next

published "Letters from the Mountains" (3 vols., London, 1806-'7), which contains descriptions of highland scenery, character, and legends. Her "Memoirs of an American Lady" (2 vols., 1808) gives a pleasant picture of her own childhood and of colonial life in America. Other works are, "Essays on the Superstitions of the Highlanders of Scotland" (2 vols., 1811), and "Eighteen Hundred and Thirteen, a Poem" (1814). After 1810 she resided in Edinburgh, and toward the close of her life she received a pension of £100. In 1844 appeared the "Memoir and Correspondence of Mrs. Grant of Laggan" (3 vols.), the memoir being an autobiography, continued by her son, John Peter Grant, who died in Edinburgh in 1871.

**GRANT, Sir Francis**, a Scottish artist, born in Edinburgh, Jan. 18, 1803, died Oct. 5, 1878. His talent for painting was encouraged by Sir Walter Scott, and he first exhibited in 1834. In 1837 he executed for the earl of Chesterfield "The Meet of his Majesty's Staghounds," with more than 40 portraits of noted sportsmen. Subsequently he produced "Melton Hunt," which was purchased by the duke of Wellington. Afterward he became distinguished as a portrait painter, and executed numerous pictures of beautiful women and celebrated men. In 1866 he succeeded Eastlake as president of the royal academy.

**GRANT, James**, a British journalist, born in Elgin, Scotland, in 1806. He started the "Elgin Courier" in 1827, and removed to London in 1834, where he soon formed a connection with the "Morning Advertiser," and became its editor in 1850. He has published "Random Recollections of the House of Commons" (London, 1836), "The Bench and the Bar" (2 vols., 1837), "The Metropolitan Pulpit" (2 vols., 1839), "Travels in London," "Portraits of Public Characters," and "Paris and its People." His "God is Love" and "Our Heavenly Home" have passed through many editions. In 1871 he published in two volumes "The Newspaper Press, its Origin, Progress, and Present Position."

**GRANT, James**, a Scottish novelist, born in Edinburgh, Aug. 1, 1822. His father was an officer in the British army, and his own education was mostly received in barracks in British North America. After serving for a short time in the 62d regiment as ensign, he resigned his commission in 1840, and devoted himself to literature. He has been a voluminous writer of military and historical romances, some of which have had a very extensive circulation in a cheap form. His chief publications are: "The Romance of War" (4 vols., 1846-'7); "Adventures of an Aide-de-Camp" (1848); "Memoirs of Kirkcaldy of Grange" (1849); "Walter Fenton, or the Scottish Cavalier" (1850); "Bothwell, or the Days of Mary, Queen of Scots" (1851); "Jane Seton" (1853); "Harry Ogilvie" (1856); "Dick Rodney" (1862); "Second to None" (1864); "The White Cockade" (1867); and "Under the Red

Dragon" (1872). Most of his works have been reprinted in the United States; some have been translated into French, and all into Danish and German. Mr. Grant is a frequent contributor to periodicals.

**GRANT, James Augustus**, a British traveller, born in Nairn, Scotland, in 1827. He was educated at Marischal college, Aberdeen. In 1845 he received an appointment in the Indian army, took part in both sieges of Mooltan and in the battle of Guzerat, and was with Havelock at Lucknow. In 1861 he accompanied Capt. Speke on his second expedition to the lake region of central Africa. After traversing a district never before visited by white men, they reached Gondokoro in March, 1863, whence they soon after returned to England. Capt. Grant furnished the designs of the maps and engravings in Speke's "Journal of the Discovery of the Source of the Nile," and in 1864 published "A Walk across Africa, or Domestic Scenes from my Nile Journal." In 1866 he was made a commander of the bath. In 1868 he accompanied Lord Napier in the Abyssinian expedition as head of the intelligence department, and was nominated a commander of the order of the star of India for his services. He is now (1874) a major in the Bengal army.

**GRANT, Sir James Hope**, a British soldier, brother of Sir Francis Grant, born at Kilgraston, Perthshire, July 22, 1808, died March 7, 1875. He was brigade major under Lord Saltoun in the first English war against China. He served through the campaign in the Punjab in 1848-'9, continued in the Indian service, and was made brevet colonel in 1854, and major general and knight commander of the bath in 1858. The last distinction was conferred upon him especially in recognition of distinguished service at the siege of Delhi, the relief of Lucknow, and the operations at Cawnpore. He was put in command of the British forces in China in 1859, and conducted the campaign there to its successful termination in the capture of Peking in 1860. For this he was formally thanked by parliament, and made a knight grand cross of the bath. In 1861 he was made lieutenant general and commander-in-chief at Madras, in 1867 quartermaster general at headquarters, and in 1871 commander of the division at Aldershot. In January, 1874, a compilation from his private journals during his Indian campaigns was published in London, under the title of "Incidents in the Sepoy War, 1857-'8."

**GRANT, Ulysses S.**, eighteenth president of the United States, born at Point Pleasant, O., April 27, 1822. His ancestors were Scotch. In 1823 his parents removed to the village of Georgetown, O., where his boyhood was passed. He entered West Point military academy in 1839, appointed by the Hon. Thomas L. Hamer, member of congress. His name originally was Hiram Ulysses; but the appointment was blunderingly made out for Ulysses S., and so it had to remain. The study in which he showed

most proficiency during his course at the academy was mathematics. He graduated in 1843, ranking 21st in a class of 39, and was made a brevet second lieutenant of infantry and attached as a supernumerary lieutenant to the 4th regiment, which was stationed on the Missouri frontier. In the summer of 1845 the regiment was ordered to Texas, to join the army of Gen. Taylor. On Sept. 30 Grant was commissioned as a full lieutenant. He first saw blood shed at Palo Alto, May 8, 1846, and took part also in the battles of Resaca de la Palma and Monterey, and the siege of Vera Cruz. In April, 1847, he was made quartermaster of his regiment, but still participated in all active operations; and after the battle of Molino del Rey, Sept. 8, 1847, he was appointed on the field a first lieutenant for his gallantry. In his report of the battle of Chapultepec (Sept. 13, 1847) Col. Garland, commanding the first brigade, said: "The rear of the enemy had made a stand behind a breastwork, from which they were driven by detachments of the 2d artillery under Capt. Brooks and the 4th infantry under Lieut. Grant, supported by other regiments of the division, after a short but sharp conflict." "I must not omit to call attention to Lieut. Grant, 4th infantry, who acquitted himself most nobly, upon several occasions, under my own observation." Grant was brevetted captain for his conduct at Chapultepec, to date from the battle. After the capture of the city of Mexico he returned with his regiment, and was stationed first at Detroit, and then at Sackett's Harbor. In 1848 he married Miss Julia T. Dent of St. Louis, sister of one of his classmates. In 1852 he accompanied his regiment to California and Oregon, and while at Fort Vancouver, Aug. 5, 1853, was commissioned full captain. On July 31, 1854, he resigned, and removed to St. Louis, cultivating a farm near that city and engaging in business as a real estate agent. In 1859 he was employed by his father in the leather trade at Galena, Ill.—When the civil war broke out, he was chosen to command a company of volunteers, with which he marched to Springfield. There he was retained as an aid to Gov. Yates, and acted as mustering officer of Illinois volunteers until he became colonel of the 21st regiment, his commission dating from June 17, 1861. He joined his regiment at Mattoon, organized and drilled it at Caseyville, and then crossed into Missouri, where it formed part of the guard of the Hannibal and Hudson railroad. On July 31 he was placed in command of the troops at Mexico, forming a part of Gen. Pope's force. On Aug. 23 he was promoted to brigadier general of volunteers, the commission being dated back to May 17, and assumed command of the troops at Cairo, which were soon increased by the addition of Gen. McClelland's brigade. He seized Paducah, at the mouth of the Tennessee, on Sept. 6, and Smithland, at the mouth of the Cumberland, on the 25th. In a proclamation to the citizens of Paducah he said: "I have

nothing to do with opinions, and shall deal only with armed rebellion and its aiders and abettors." On Oct. 16 he sent out a detachment under Col. Plummer to check the advance of the confederate forces under Gen. Jeff Thompson, which was accomplished by a battle at Fredericktown, Mo., on the 21st. On Nov. 7, with two brigades, Grant fought the battle of Belmont, where he commanded in person and had a horse shot under him. Gen. Halleck, on assuming command of the department of Missouri, gave Gen. Grant the command of the district of Cairo (Dec. 21), which was so extended as to form one of the largest military divisions in the country, including the southern part of Illinois, that portion of Kentucky west of the Cumberland river, and the southern counties of Missouri. After a reconnaissance in force toward Columbus in January, 1862, Grant started on Feb. 3 from Paducah, with a force of 15,000 men, aided by Commodore Foote with a fleet of gunboats, for the capture of Forts Henry and Donelson, the former of which commanded the Tennessee river, and the latter the Cumberland, near the dividing line between Kentucky and Tennessee. Fort Henry, commanded by the confederate Gen. Tilghman, surrendered on Feb. 6, and Fort Donelson, commanded by Gen. Buckner, on the 16th. The reduction of Fort Henry was mainly the work of the gunboats; Fort Donelson was only captured after a severe battle (Feb. 15), in which the federal forces, which had been increased to 30,000 or more, sustained a loss of 2,300. In answer to Buckner's proposal that commissioners be appointed to arrange the terms of capitulation, Grant wrote: "No terms other than an unconditional and immediate surrender can be accepted. I propose to move immediately upon your works." The capture of Fort Donelson with all its defenders except Gen. Floyd's brigade was the first brilliant and substantial victory that had crowned the federal arms. To the gratification at so great a military success was added a popular admiration of the terse and soldierly declaration in which the surrender had been demanded; and the hero of the affair sprang at once into national celebrity. He was immediately commissioned major general of volunteers, to date from Feb. 16. Gen. C. F. Smith had been directed by Gen. Halleck to make an expedition up the Tennessee with about 40,000 men; but he died soon after it started, and the command devolved upon Gen. Grant. A large portion of the force, after lying three weeks at Pittsburgh Landing, in preparation for an attack on Corinth, was surprised at daybreak of April 6 by an overwhelming confederate force under Gen. A. S. Johnston, driven from its camp, and routed with heavy loss. Gen. Grant arrived on the field of battle at 8 A. M., and reformed the lines. Heavy reinforcements, under Gen. Buell, having arrived in the night, the battle was renewed on the 7th, and the enemy, defeated, withdrew

to Corinth. The loss on each side was about 12,000. Gen. Grant was slightly wounded. Gen. Halleck, arriving at the front two or three days afterward, began siege operations against Corinth; but the confederates evacuated the place on the last days of May. Halleck was called to Washington on July 11, and Grant became commander of the department of West Tennessee, with headquarters at Corinth. The most serious problem that demanded his immediate attention was the disposal of guerillas, spies, and traders, who were crossing the lines on all sorts of pretexts, carrying information and stores to the enemy. He issued several severe orders against them, took possession of all unoccupied buildings in Memphis and rented them for the benefit of the United States government, and gave the Memphis "Avalanche" the alternative of suspending publication or dismissing an editor who had written an "incendiary and treasonable" article. On Sept. 17 Grant ordered an advance from Corinth, to stop the progress of the confederate Gen. Price, who had a large force concentrated at Iuka. A battle was fought at this place, Sept. 19, and a complete victory gained. As Gen. Bragg's force was pushing toward the Ohio river, Grant now removed his headquarters to Jackson, Tenn. The confederates under Price and Van Dorn, 40,000 strong, attacked his position at Corinth, which was held by Rosecrans with about 20,000 (Oct. 3 and 4). After a desperate fight, the assailants were repulsed with heavy loss and pursued beyond the Hatchie river. Buell moved out to intercept Bragg, and defeated him at Perryville, Oct. 8, whereupon he retreated to East Tennessee. On the 16th Gen. Grant's department was extended by the addition of a portion of Mississippi, as far as Vicksburg, and designated as the department of the Tennessee; the forces under his command were constituted the 13th army corps. The most stringent measures were taken to prevent plundering and illegal trading, as necessary to military discipline under the peculiar circumstances of an army so placed in a mingled community of friends and foes. After unsuccessful movements against Vicksburg, "the Gibraltar of the Mississippi," from the north, and the loss of an immense quantity of stores which the confederates (Dec. 20) seized and destroyed at Holly Springs, Grant moved his army down the west bank of the river, crossed to the east side at a point below the city on the last day of April, 1863, defeated the enemy in the actions of Raymond, Jackson, Champion's Hill, and Big Black, preventing Gen. J. E. Johnston from joining Pemberton at Vicksburg, and laid siege to that place, May 18. The city was surrendered, with about 27,000 prisoners, on July 4, 1863. Thereupon Grant was promoted to the rank of major general in the regular army. In October he was placed in command of the military division of the Mississippi, comprising the departments commanded by Sherman,

Thomas, Burnside, and Hooker. Immediately after the capture of Vicksburg he had sent heavy reinforcements to Gen. Sherman on the Big Black river, who was thereby enabled to drive the confederate force under Johnston out of Jackson. Grant concentrated his forces for the defence of Chattanooga, which was threatened by Bragg, and the latter's positions on Missionary ridge and Lookout mountain were carried by assault on Nov. 24 and 25. Bragg's forces retreated to Dalton, Ga., being followed as far as Ringgold. The pursuing columns were then sent to the relief of Knoxville, which, held by Burnside, was closely invested by Longstreet. Gen. Halleck, in his annual report, said: "Considering the strength of the rebel position and the difficulty of storming his intrenchments, the battle of Chattanooga must be considered the most remarkable in history. Not only did the officers and men exhibit great skill and daring in their operations on the field, but the highest praise is due to the commanding general for his admirable dispositions for dislodging the enemy from a position apparently impregnable. Moreover, by turning his right flank and throwing him back upon Ringgold and Dalton, Sherman's forces were interposed between Bragg and Longstreet, so as to prevent any possibility of their forming a junction." The first measure passed in the congressional session of 1863-4 was a resolution providing that a gold medal be struck for Gen. Grant, and returning thanks to him and his army. Resolutions of thanks were also passed by the legislatures of New York and Ohio. A bill reviving the grade of lieutenant general in the army was passed by congress, and on March 1, 1864, received the signature of President Lincoln, who at once nominated Gen. Grant for the position. The senate confirmed the nomination on the following day. On the eve of starting for Washington to receive the commission, Grant wrote a letter to Gen. Sherman, in which he said: "Whilst I have been eminently successful in this war, in at least gaining the confidence of the public, no one feels more than I how much of this success is due to the energy, skill, and the harmonious putting forth of that energy and skill, of those whom it has been my good fortune to have occupying subordinate positions under me. There are many officers to whom these remarks are applicable to a greater or less degree, proportionate to their ability as soldiers; but what I want is, to express my thanks to you and McPherson, as the men to whom, above all others, I feel indebted for whatever I have had of success." Grant arrived in Washington on March 9, received his commission at the hands of the president, and on the 17th issued his first general order, dated at Nashville, assuming command of the armies of the United States, and announcing that headquarters would be in the field, and until further orders with the army of the Potomac. Not before during the civil war had any one

general in the field commanded all the national armies. Grant, with nearly 700,000 men in the field, at once planned two campaigns, to be directed simultaneously against vital points of the confederacy by the two chief armies under his command: the one, under Gen. Meade, to operate against Richmond, defended by Lee; the other, under Gen. Sherman, against Atlanta, defended by Johnston. At midnight on May 3 Grant began the movement against Richmond, crossing the Rapidan with the army of the Potomac, which was joined two days later by the 9th corps under Burnside, and, with an aggregate force of 140,000 men, pushing through the Wilderness by the right of Lee's position, in the endeavor to place himself between the confederate army and the confederate capital. Lee was apprised of the movement on the morning of the 4th, and boldly took the offensive, pushing eastward to strike the federal columns on the march. The immediate result was the bloody battle of the Wilderness, which foiled Grant's first attempt to interpose his army between Lee's and Richmond. Making another advance by the left flank, he was again confronted by Lee at Spottsylvania; and after partial success and a bloody repulse, he repeated the movement again, only to find Lee in a strong position on the North Anna river; and still a fourth advance brought the army of the Potomac before the absolutely impregnable rifle pits of Cold Harbor. After a costly assault on these, Grant once more moved his army by the left flank and crossed the James. The day after the success of Spottsylvania he had sent a despatch to the government, which closed with these words: "I propose to fight it out on this line if it takes all summer." His losses in the campaign from the Rapidan to the James (May 3 to June 15) were 54,551, killed, wounded, and missing. Lee's losses were about 32,000. Sherman opened his campaign toward Atlanta as soon as Grant telegraphed to him that the army of the Potomac had crossed the Rapidan. At the same time Grant had directed Sigel to advance from Winchester up the Shenandoah toward Staunton, and Crook to advance from Charleston up the Kanawha toward Lynchburg. But Sigel was defeated at Newmarket by Breckinridge, and Crook, after considerable fighting, was compelled to retreat. Meanwhile Gen. Butler, with the army of the James, had been directed to capture and hold Petersburg, and if possible to invest Richmond closely from the south side, but had totally failed to do so. All these flanking movements being foiled, and Lee being neither defeated in the open field nor cut off from Richmond, the great problem of the war instantly narrowed itself down to a siege of Petersburg, which Grant now began. Lee's attempt to create a diversion by an invasion of Maryland and an attack on Washington failed, Sheridan ultimately driving back the invaders up the valley of the Shenandoah; while, in Georgia,

Johnston was unable to check the advance of Sherman, and his successor in command, Hood, was forced to evacuate Atlanta, and lost his army before Nashville. The siege of Petersburg ended, after the victory at Five Forks, in the beginning of April, 1865, when Richmond was evacuated and Lee retreated westward toward Danville, followed closely by Grant, who finally forced the surrender of his remaining force, which took place at Appomattox Court House, April 9.—After the war Grant fixed his headquarters at Washington; and on July 25, 1866, he was commissioned general of the United States army, the rank having been created for him. On Aug. 12, 1867, when President Johnson suspended Secretary Stanton from office, Gen. Grant was made secretary of war *ad interim*, and held the position until Jan. 14, 1868, when he returned it to Mr. Stanton, whose removal the senate had refused to sanction. The president wished Grant to retain the office notwithstanding the action of congress, and Grant, in a letter to him dated Feb. 3, closing a somewhat tangled correspondence, said: "I can but regard this whole matter, from the beginning to the end, as an attempt to involve me in the resistance of law for which you hesitated to assume the responsibility in orders, and thus to destroy my character before the country. I am, in a measure, confirmed in this conclusion by your recent orders directing me to disobey orders from the secretary of war, my superior and your subordinate, without having countermanded his authority to issue the orders I am to disobey." At the republican national convention held in Chicago May 21, 1868, Gen. Grant on the first ballot was unanimously nominated for president, with Schuyler Colfax for vice president. Their democratic competitors were Horatio Seymour and Francis P. Blair. Grant and Colfax carried 26 states, and received 214 electoral votes, against 80 for Seymour and Blair. Grant was inaugurated president on March 4, 1869, and on the next day sent in to the senate the following nominations for cabinet officers: Elihu B. Washburne of Illinois, secretary of state; Alexander T. Stewart of New York, secretary of the treasury; Jacob D. Cox of Ohio, secretary of the interior; Adolph E. Borie of Pennsylvania, secretary of the navy; John M. Schofield of Illinois, secretary of war; John A. J. Creswell of Maryland, postmaster general; E. Rockwood Hoar of Massachusetts, attorney general. These nominations were at once confirmed, but it was discovered that Mr. Stewart was disqualified by an act of 1789, which provided that no person should hold the office of secretary of the treasury who was "directly or indirectly concerned or interested in carrying on the business of trade or commerce." The president, in a brief message, thereupon suggested to congress that Mr. Stewart be exempted by joint resolution from the action of the law. This was objected to, and Mr. Stewart declined, and George S. Boutwell of Massa-

chusetts was appointed in his stead. Soon afterward Mr. Washburne gave up the office of secretary of state, being appointed minister to France, and was succeeded by Hamilton Fish of New York; while Secretary Schofield retired from the war department, and was succeeded by John A. Rawlins of Illinois, who died in September, when the vacancy was filled by the appointment of William W. Belknap of Iowa. Mr. Borie resigned in June, and was succeeded by George M. Robeson of New Jersey. Mr. Hoar resigned in July, 1870, and was succeeded by A. T. Akerman of Georgia, who resigned in December, 1871, and was succeeded by George H. Williams of Oregon. Mr. Cox resigned in November, 1870, and was succeeded by Columbus Delano of Ohio. As President Grant was in political harmony with the majority in congress, the reconstruction of the lately rebellious states, which had been delayed by the lack of such harmony during the previous administration, now went on. A proclamation by President Grant, dated May 19, directed that there should be no reduction of the wages paid to government employees in consequence of the reduction in the hours of labor which congress had enacted. In 1871 President Grant urged the annexation of Santo Domingo as a territory of the United States. A treaty to effect this, and also one by which the peninsula and bay of Samana were ceded to the United States for 50 years at an annual rental of \$150,000 in gold, had been signed Nov. 29, 1869, on behalf of President Grant and President Baez. Early in 1870 these treaties were confirmed by a popular vote in Santo Domingo; but it was believed that a free election had not been held, and it was said that, in anticipation of annexation, the Dominican government had granted to private individuals every valuable franchise or piece of property in its possession. In conformity with a resolution of congress, President Grant appointed B. F. Wade of Ohio, A. D. White of New York, and S. G. Howe of Massachusetts, as commissioners to visit Santo Domingo, accompanied by several scientific men, and report upon the condition of the country, the government, and the people. Their report, submitted in April, 1871, was favorable to annexation; but the senate withheld its approval of the treaties. A "joint high commission" of five British and five American members met at Washington, Feb. 27, 1871, and on May 8 signed a treaty on the subject of the coast fisheries, river navigation, and the "Alabama claims." The last named question was submitted to a court of arbitration to meet at Geneva, Switzerland, which on Sept. 14, 1872, awarded the gross sum of \$15,500,000, to be paid by the British government to the United States for damages to American commerce by confederate cruisers fitted out in British ports. The act to enforce the provisions of the 14th amendment of the constitution, popularly known as the Ku-Klux bill,

was followed by a presidential proclamation exhorting obedience to it; and on Oct. 17, 1871, the president suspended the privilege of habeas corpus in the northern counties of South Carolina. Under the provisions of an act of congress of March 3, 1871, President Grant appointed a board of seven commissioners to inquire into the condition of the civil service and devise a plan for rendering it more efficient. The chairman of the board, George William Curtis, resigned in March, 1873, because of essential differences between his views and the president's on the enforcement of the rules. At the national republican convention held in Philadelphia, June 5, 1872, President Grant was renominated by acclamation, and Henry Wilson of Massachusetts received the nomination for vice president; while Horace Greeley and B. Gratz Brown were the candidates of both the liberal republicans and the democrats. Grant and Wilson received 286 votes in the electoral college, against 80 for other candidates. Grant's popular majority over Greeley was 762,991. During the last session of the 42d congress the salary of the president was doubled, and those of the vice president, speaker of the house, justices of the supreme court, and heads of departments increased 25 per cent. William M. Richardson of Massachusetts became secretary of the treasury March 4, 1873, and was succeeded on June 2, 1874, by Benjamin H. Bristow of Kentucky. On the death of Chief Justice Chase in 1873, the president nominated successively George H. Williams, Caleb Cushing, and Morrison R. Waite of Ohio; the last named was confirmed. On April 22, 1874, he vetoed a bill to increase the currency. He retired from office at the close of his second term, March 4, 1877, and on the 17th of May embarked at Philadelphia, with his wife and his elder son, for a tour around the world. After visiting nearly every country of Europe, where he was received with distinguished honors by the crowned heads, the ex-president embarked at Marseilles, Jan. 24, 1879, and arrived at Bombay on the 12th of February. In India, Burma, China, and Japan, he met with similar receptions to those which had been extended to him in Europe; and on the 25th of August he sailed from Yokohama for San Francisco, where he landed on Sept. 20. At the close of the year he visited the West Indies and Mexico.—In the republican national convention held in Chicago in June, 1880, Gen. Grant received on the first ballot 304 votes for the presidential nomination; on the 34th ballot he received 312; and on the 36th (when Garfield was nominated), 307.—Accounts of the battles fought by Gen. Grant will be found under their respective titles. See "Military History of Ulysses S. Grant," by Adam Badeau (3 vols., New York, 1868-'81); "Life of Ulysses S. Grant," by C. A. Dana and J. H. Wilson (Springfield, 1868); and "Report of the Operations of the Union Army from March,

1862, to the Close of the Rebellion" (New York, 1866).

**GRANVELLE, Antoine Perrenot**, cardinal de, a Spanish statesman, born in Besançon, Aug. 20, 1517, died in Madrid, Sept. 21, 1586. He was the son of Nicolas Perrenot, the chancellor and minister of the emperor Charles V. He was educated at Dôle, Padua, and Louvain, and mastered seven languages. At the age of 23 he was appointed canon of Liège cathedral and bishop of Arras. At the council of Trent, in 1545, he defended the emperor's war policy against France, and obtained an appointment as councillor of state. After the battle of Mühlberg (1547) he drew up the treaty of peace. In 1550 he succeeded his father as chancellor. He accompanied the emperor on his flight from Innsbruck in 1552, and displayed great ability in negotiating the treaty of Passau, which followed it. On the accession of Philip II. in 1555, Granvelle became his minister, and delivered on his behalf an eloquent address to the Flemish people. While Philip remained in the Netherlands he was guided by the counsels of his minister. The regulations in reference to Protestantism, adopted in 1550, were reenacted in 1556. The Spaniards having gained the victory of St. Quentin over the French, Granvelle was instrumental in negotiating the treaty of Cateau-Cambrésis, which was signed in 1559. Soon afterward Philip II. returned to Spain, and left Margaret of Parma regent of the Netherlands; but with her was associated a council, advisory power in doubtful and important cases being reserved to a *consulta* consisting of three members of the council. Granvelle was one of this select body, and had the other two completely under his control; and it was soon obvious that he wielded all the power of Spain in the Netherlands. His paramount object was the restoration of the supremacy of the Catholic church. Spanish troops were retained in the country; the general assembly of the states was not called together; and 13 new bishoprics were created. In 1560 Granvelle was made archbishop of Mechlin, and primate. But what incensed the people most was the preparations for the introduction of the Spanish inquisition. In 1561 he was created a cardinal. At last even Margaret of Parma yielded to the pressure and joined in the request for his recall. But it was not until Granvelle himself had signified his acquiescence that Philip II. commanded him "to leave the Low Countries for a few days, and go to Burgundy to see his mother." He obeyed the command in 1564, and never returned. He retired to Besançon, and occupied himself with literature and the physical sciences. In 1565 he went to Rome by the king's order, and participated in the election of Pope Pius V. In 1570 he was employed to negotiate the alliance between Spain, Rome, and Venice against the Turks. He next became viceroy of Naples, and in 1575 was recalled to Madrid, where Philip made him president of

the supreme council of Italy and Castile. He negotiated the terms of union between Spain and Portugal, and when Philip went to take possession of his new kingdom, Granvelle acted as regent during his absence. He enriched the college of Besançon, founded by his father, and contributed largely to support the printing establishment of Plantin at Antwerp. He left a large number of letters and documents, which eighty years afterward were assorted by the abbé Boissot, forming 82 volumes. A selection from them has been published by the French government (9 vols. 4to, 1841-'61).

**GRANVILLE**, a N. county of North Carolina, bordering on Virginia, intersected by Tar river and watered by the Neuse river; area, about 750 sq. m.; pop. in 1870, 24,831, of whom 13,355 were colored. The surface is slightly hilly, and the soil generally good. The chief productions in 1870 were 110,209 bushels of wheat, 306,113 of Indian corn, 115,593 of oats, 16,484 of Irish and 34,298 of sweet potatoes, 129,595 lbs. of butter, 2,134,228 of tobacco, and 277 bales of cotton. There were 2,722 horses, 4,073 milch cows, 4,828 other cattle, 881 sheep, and 18,986 swine; 2 iron founderies, and 39 manufactories of tobacco. The county is traversed by the Raleigh and Gaston and the Roanoke Valley railroads. Capital, Oxford.

**GRANVILLE**, a village of Licking co., Ohio, pleasantly situated on an affluent of Licking river, 3 m. from the Central Ohio division of the Baltimore and Ohio railroad, and 25 m. E. N. E. of Columbus; pop. in 1870, 1,109. The town is neatly built. Denison university (Baptist) was organized in 1831, and in 1872 had 10 professors and instructors, 191 students (71 collegiate), and a library of 11,000 volumes. The scientific department, organized in 1854, had 21 students. The Granville female college had 8 instructors and 111 students; and the young ladies' institute (Baptist) had 8 instructors and 115 students.

**GRANVILLE**, a seaport town of Normandy, France, in the department of La Manche, on the English channel, at the mouth of the Bosq, 29 m. S. W. of St. Lô; pop. in 1866, 15,622. It has a small harbor with a fine granite pier capable of mounting cannon, is built in terraces formed on the side of a promontory, is surrounded with walls, and has a fort on the summit of the promontory. The town has a school of navigation, and the inhabitants are chiefly engaged in the cod and oyster fishery.

**GRANVILLE, George**, Baron Lansdowne, an English author and statesman, born in 1667, died Jan. 30, 1735. He entered Trinity college, Cambridge, at the age of 10, and three years later received the degree of M. A. About the same time he began to write poetry, and on the accession of James II. addressed several pieces of verse to him. During the reign of William and Mary he lived in retirement and wrote several plays, one of which, "Heroic Love," is highly praised in a passage of Dryden. His "British Enchanters" was per-

formed 40 times. Becoming by the death of his father and elder brother the head of the influential family of Granville, he entered parliament in 1710, and in the same year was appointed secretary of war in place of Walpole. In January, 1712, he was created Baron Lansdowne of Biddeford. Upon the queen's death he lost his offices, and, on account of his avowed sympathy for the pretender and his participation in the scheme for raising an insurrection in the west of England, was committed to the tower in September, 1715, where he was confined till Feb. 8, 1717. Being suspected again in 1722 of some connection with the Atterbury plot, he retired to France, and returning to England in 1732 published his works in prose and poetry in 2 vols. 4to.

**GRANVILLE, Granville George Leveson Gower**, second earl, a British statesman, born in London, May 11, 1815. He was educated at Eton and Oxford, and entered public life in 1835 as attaché to the British embassy at Paris, of which his father, the first Earl Granville, a well known diplomatist, was the head. In 1836 he was returned to parliament for the borough of Morpeth, subsequently became under secretary of state for foreign affairs, and sat for Lichfield from September, 1841, to January, 1846, when he succeeded to his title. He held the seals of the foreign office in the Russell cabinet from December, 1851, to February, 1852, and was lord president of the council from December, 1852, to June, 1854, from February, 1855, to February, 1858, and from June, 1859, to June, 1866. In 1868 he again became a member of the cabinet as secretary of state for the colonies. In the house of lords he was a leader in debate, and ably sustained liberal views in regard to the Irish church bill, 1869, and the land bill, 1870. On the death of Lord Clarendon in 1870 he became secretary for foreign affairs. He resigned with the other members of the Gladstone cabinet in February, 1874.

**GRANVILLE, John Carteret**, earl, an English statesman, born in Bedfordshire, April 22, 1690, died Jan. 2, 1763. He was educated at Westminster school and at Oxford, and as Baron Carteret took his seat in the house of lords in 1711. His zeal in support of the Protestant succession caused George I. to promote him in 1715 to be bailiff of the island of Jersey, and in 1716 to be lord lieutenant of Devonshire. In 1718 he was ambassador to Sweden; in 1720 ambassador extraordinary at the congress of Cambrai; from May, 1721, to April, 1724, secretary of state; and from that time till 1730, with a brief intermission, he was lord lieutenant of Ireland. Afterward he was prominent in the debates in the house of lords till February, 1742, when he was again made secretary of state, and in September following was sent to the states general to assist in devising measures to maintain the liberties of the United Provinces. The succeeding year he passed with the king in Hanover. In 1744, by the death of his mother, he succeeded to

the title of Earl Granville, and shortly after he was compelled to resign his office. During his parliamentary career he was conspicuous for his speeches on questions arising from the Edinburgh riots, and he was the mover for the settlement of £100,000 a year from the civil list on the Prince of Wales. Macaulay says: "No public man of that age had greater courage, greater ambition, greater activity, greater talents for debate or for declamation. No public man had such profound and extensive learning. His knowledge of modern languages was prodigious. He spoke and wrote French, Italian, Spanish, Portuguese, German, even Swedish." He alone of the ministers of George I. could converse with the monarch in his native tongue. His ministry was popularly termed the "drunken administration," an expression not altogether figurative, for Granville's habits were extremely convivial, and champagne lent its aid to keep him in that state of joyous excitement in which his life was passed. No misfortune could depress him. His spirits were constantly high. When driven from office, says Macaulay, "he retired laughing to his books and his bottle." Ill as he had been used, he did not seem, says Horace Walpole, "to have any resentment, or indeed any feeling except thirst."

**GRAPE**, the fruit of woody vines of the genus *vitis* (the ancient Latin name), the type of the order *vitaceæ*, which includes shrubs climbing by tendrils. At each node or joint of the grape-vine is borne a leaf, with a tendril or flower cluster upon the opposite side; the leaves are long-petioled, palmately veined, variously lobed and smooth or downy in different species; in the axil of each leaf are produced two buds, one of which develops the same season, producing what the vineyardist calls "laterals," while the other remains dormant as a provision for the growth of the following year. The tendrils are branched; the branches have hooks at the ends, and when these catch hold of some supporting object the tendril coils spirally, rapidly becomes woody, and holds the vine with great firmness. The tendril may be considered as a modified branch, which in some cases bears flowers and fruit; nothing is more common than to find in our native vines clusters in which one of their branches retains its tendril character and helps to hold up the fruit. The flowers of the wild grape are sometimes diœcious, but in cultivated ones perfect; they are very small; the calyx short and lined with a disk, which bears the petals and stamens; petals five, cohering at the apex, and forming a little cap which in flowering falls off entire; stamens five, with a gland or lobe of the disk between each pair; a single pistil, with a two-lobed stigma, has a two-celled ovary with two ovules in each cell; this in ripening becomes a one- to four-seeded berry. The flowers of the grape are delightfully fragrant, recalling the odor of mignonette. Grapes are found in the temperate climates of both

hemispheres. There is at present some confusion about the species, but in a horticultural view they are divided into European and American grapes. The European grape, *vitis vinifera*, is the species that in some of its numerous varieties is cultivated in most European

European Grape (*Vitis vinifera*).

and Asiatic countries. Regel, the distinguished botanist and director of the imperial gardens at St. Petersburg, has recently given the somewhat startling opinion that *V. vinifera* is not a true species, but a hybrid between *V. labrusca* and *V. vulpina*, both of which are natives of North America, Japan, Mantchooria, and the Himalaya. He bases his opinion upon the facts that the European vine is not found in a truly wild state, but only as an escape from cultivation, and that the two species suggested as its parents are found wild in that portion of Asia in which the cultivation of the vine originated. Whatever may have been its origin, it will continue to be known by our cultivators as the European or foreign grape. Very early in the history of America attempts were made to cultivate the foreign grape in the open air, and these have been repeated from time to time up to the present day; but in no instance have they met with success east of the Rocky mountains. In exceptionally favorable localities, as in city yards, the foreign vine has here and there succeeded for a few years; but in order to grow it with certainty it must have the protection of glass. Upon the Pacific coast the case is different; the Jesuit missionaries early discovered that the soil and climate were adapted to the foreign grape, and after California was settled by Americans grape culture, confined almost exclusively to foreign varieties, became one of the important industries of the state. (See AMERICAN WINES.) The foreign vine is distinguished from American species principally by the character of the fruit; in the latter the seeds are enveloped and held together by a

more or less firm pulp, which slips from the skin, while a foreign grape may be broken open with the pulp still adhering to the skin, and the seeds so free from it that they will fall out or may be readily separated. The cultivation of the foreign grape under glass is followed to a considerable extent both as a matter of luxury and of profit. Two modes of culture are practised: in the cold grapery, which is a glass house without artificial heat, and in the forcing grapery, which is heated and the vines brought into growth and fruiting at such times as are desired. For details reference may be had to special treatises.—Of American species of the genus *vitis* producing edible fruit, botanists recognize four: *V. labrusca*, the northern fox grape; *V. aestivalis*, the summer grape; *V. cordifolia*, the frost grape; and *V. vulpina*, the muscadine or southern fox grape. Several grapes from west of the Mississippi have been described as distinct species by some botanists, but others regard them as only forms of the above. The American grapes differ so much in the wild state, in form of leaf and size, shape, and color of the fruit, that it is often difficult to decide to which species a specimen should be referred; and when they are subjected to cultivation the variation is still more strongly marked. In no branch of fruit culture has there been greater progress than in the cultivation of American grapes. Twenty-five years ago the Catawba and Isabella were the only kinds grown to any considerable extent, while at the present time the varieties are numbered by hundreds, and additions are yearly made to the list. In the article AMERICAN WINES the leading varieties are named, and the species from which they are supposed to have originated indicated. In the vineyards of the eastern states the growing of the fruit for market is quite as important as raising it for wine, and in the wine districts the fruit is packed and shipped as table fruit so long as it will bring a price above that at which it can be profitably crushed for wine. By keeping them at a low temperature some varieties may be preserved in good condition

Flower of the Grape, magnified.

for several months after they are gathered. Aside from the commercial value of the grape, it is of great importance as one of the few fruits that can be conveniently produced in cities and towns. While judicious treatment is essential to the best results, it will grow

and bear fruit under the most adverse circumstances, and it is cultivated for its abundant shade as well as for its fruit. Within a few years a new class of grapes has sprung up, produced by hybridizing native varieties with the foreign. Mr. Rogers of Salem, Mass., was the first to attempt this upon an extensive scale, but the varieties he produced are not very strongly marked with the characteristics of the foreign vine. Dr. Wylie of Chester, S. C., Mr. Underhill of Croton Point, N. Y., and others, have produced varieties which in the fruit make a near approach to the exotic grape, while the foliage is more like that of its native parent.—The vine is propagated with the greatest ease by layers and from cuttings; in commercial nurseries the propagation is from cuttings, except with a few varieties that take root with difficulty, and these are grown from layers. Cuttings of the last season's growth of wood removed in the autumn pruning, with two or three buds upon each, are buried in a dry place until spring, and then set out in rows with one bud at the surface of the ground and the others below; with some varieties a large percentage of such cuttings will form roots and make salable vines by autumn; other kinds are very uncertain when treated in this way, and these are started under glass, from what are called single eyes, which consist of one bud with a short piece of the wood attached; these eyes are planted in a bed of sand, and by a proper management of heat and moisture roots and leaves are soon formed, when the young plants are transferred to a rich soil. Vines are sometimes propagated, especially in the case of rare kinds, from cuttings of green shoots, but planters do not approve of vines thus produced. In the matter of pruning and training there is a considerable difference of opinion and practice among vineyardists, but they all agree in controlling the growth of the vine within certain bounds. Whatever the system of pruning, its successful practice depends upon a knowledge of the manner of growth of the vine. The fruit of a vine is produced upon shoots which in spring push from buds upon branches or canes which grew the season before. If a young vine consisting of a single stem having 20 buds is left unpruned, the majority of these buds will develop as shoots; the few uppermost will start first and be the most vigorous, while those below will be weak; at the end of the season such a vine will have two or three strong canes above and a few slender ones below; the next year, if still unpruned, the stronger canes will follow the same course as did the single one, and the most vigorous growth and the fruit-bearing buds will be still further from the root; and if the vine be allowed to grow entirely wild for several years, fruit will be found only upon the extreme branches. One great object in pruning is to keep the fruit-bearing portion of the vine near the ground; another is to keep up a constant supply of fruit-bearing wood, and another to

so regulate the amount of fruit borne by each vine that it shall attain the greatest possible development and excellence. The methods of pruning are thoroughly discussed in the recent treatises upon grape culture.—The vine grower has many enemies to contend with, one of the most destructive of which is mildew, which consists of two or more forms or species of parasitic fungi. The most common mildew upon native grapes, *peronospora*, appears as small grayish patches of down on the under side of the leaves, and on the young shoots and fruit stalks; if not arrested, it soon destroys the foliage of the vine and checks the development of the fruit. Flowers of sulphur, frequently and persistently applied by means of a bellows invented for the purpose, will prevent the further spread of this destructive parasite. Another form of mildew, *oidium* or *erysiphe*, makes its appearance on the upper side of the leaves and on the fruit, especially upon exotic vines under glass, though in certain situations and in very dry seasons it attacks vineyards of the native grape; one form of "rot" upon the fruit is due to this. Insects of various kinds, from the time the leaf begins to expand until the fruit is gathered, demand the constant vigilance of the cultivator. Of late years a minute aphid-like insect has been discovered, though its ravages were noticed long before the cause was ascertained, the *phylloxera vastatrix*; this attacks both the roots and the leaves, but not always to the same degree in all varieties; those that have descended from the summer grape (*V.estivalis*) seem to be more exempt from its attacks than others. In Europe the devastations of this insect have been so great as to completely destroy the grape industry in parts of France as well as in other vine-growing countries. It is believed in France that the insect was introduced from this country, and in 1873 the commissioner of agriculture sent M. Planchon to investigate the habits of *phylloxera* in what they regard as its native localities. The best history of this insect will be found in the third, fourth, and fifth reports of C. V. Riley, state entomologist of Missouri, which are comprised in the reports of the Missouri state board of agriculture for 1870, '71, and '72. No satisfactory remedy has been discovered.—The principal varieties of foreign and native grapes are described in Downing's "Fruit and Fruit Trees of America" (revised ed., 1869) and other general works upon fruits. Special treatises upon the grape are numerous; the most important to the American cultivator are "American Grape Grower's Guide," by William Chorlton, and "Grape Culture and Wine Making," by A. Haraszthy, both mainly devoted to the foreign grape; "The Grape Culturist," by A. S. Fuller; "Grapes and Wine," by George Hussmann; and "Culture of the Grape," by W. C. Strong.

**GRAPE SHOT**, formerly small shot put into a canvas bag, which was corded into cylindrical form to fit the piece of ordnance from which

it was to be fired. This was superseded by canister shot, in which the balls are confined in a canister of iron plate. The term grape shot is now applied to an assemblage of iron shot fastened around a metallic spindle, giving the appearance of a bunch of grapes. The shots fly asunder as they leave the gun, and are very destructive at short distances.

**GRAPHITE** (Gr. *γράφειν*, to write), a mineral commonly called black lead or plumbago, but which titles are incorrect, as it contains no lead. Its composition is similar to that of anthracite coal, containing usually from 90 to 95 per cent. of carbon, with from 4 to 10 per cent. of iron, and traces of silica, alumina, lime, and magnesia. Specimens have been found in Ceylon said to contain 98.55 per cent. of carbon. It occurs in beds and imbedded masses and laminae, in granite, gneiss, mica schist, and crystalline limestone, and sometimes in greenstone. It is sometimes the result of alteration by heat of the coal formation, and is an ordinary artificial product of the destructive distillation of coal in the retorts of gas works. It is found in nature in both a crystalline and amorphous condition, opaque, of a metallic, steel-gray color and lustre, and giving a peculiar, shining, greasy streak on paper. Its specific gravity is 2.09, rising somewhat above this as impurities increase. Its hardness ranges between 1 and 2. Crystallized graphite occurs in six-sided tables, belonging to the hexagonal system, cleaving perfectly in the direction of the base, and having the basal planes striated parallel to the alternate sides; but the mineral is more commonly found in foliated or granular masses. It is found associated with olivine and sphene at Ticonderoga, N. Y., and in beds of gneiss at Sturbridge, Mass., usually in a scaly and granular, but sometimes approaching a crystalline form. It is also found at North Brookfield, Brimfield, and Hinsdale, Mass., at Brandon, Vt., and at Grenville, Canada, where it is associated with sphene and tabular spar. It occurs near Amity, Orange co., N. Y., in white limestone, associated with spinel, chondrodite, and hornblende; at Rossie, St. Lawrence co., with iron ore, and in gneiss; in Bucks co., Pa., near Attleboro, associated with tabular spar, pyroxene, and scapolite, and also in syenite at Mansell's black-lead mine near the same locality. There is a large deposit at St. John, N. B. The mine at Borrowdale in Cumberland, England, has long been celebrated for yielding graphite of a superior quality for making black-lead pencils, one of its principal uses. The mine has been known since the time of Queen Elizabeth, and probably furnished the first lead pencils ever made, as their invention cannot be traced back as far as the discovery of the mine. It is in a mountain, 8 m. S. of Keswick, 2,000 ft. high. The mineral occurs in small nests in trap. The pieces are about the size of the fist. The mine became so valuable as to be an object of plunder, being reached underground from neigh-

boring mines, and being once forcibly taken possession of at the surface. The graphite was of so pure a quality that it required but little preparation for the market; and much of it was sawed up in its natural state for pencils. The mine is now nearly exhausted, and has not been worked for many years. Graphite has been found in Germany, France, Austria, and South America, and in enormous masses in N. E. Siberia. Besides furnishing a material for writing pencils, it is used for making crucibles, and linings for small furnaces; as an ingredient in lubricating compounds for machinery; for giving a smooth surface to the moulds of metal castings, and for polishing stoves and iron castings generally; and also for a coating to wax or other impressions of objects designed to be electrotyped, for the purpose of forming a good conducting surface for the galvanic current. It has also been employed by Graham as a diaphragm in his diffusometer or instrument for observing the comparative rate of diffusion of gases. (See **CRUCIBLE**, and **PENCIL**.)

**GRAPTOLITES** (Gr. *γράφειν*, to write, and *λίθος*, stone), a genus of fossil aculeophs, of as many as 20 species, found only in the Silurian rocks, abounding particularly in the slates of the Hudson river group. So numerous are these early forms of zoöphytes in the Llandeilo rocks of Europe, that it has even been thought probable that the carbonaceous character of the slates was owing to the abundance of their remains. As found in the black slates, their sil-

very forms are obscurely retained, and the fossils may easily be mistaken for impressions of plants. They are long and slender, resembling some algae, as well as the feather part of a quill, whence their name. When found in calcareous strata their forms are more distinct. Their nearest living analogues are the sea firs or sertularians, of which the species inhabit muddy sediment, such as the black slates must once have been.

**GRASS CLOTH.** See **RAMIE**.

**GRASSE, La**, a town of S. E. France, in the department of Alpes-Maritimes, 18 m. W. of Nice; pop. in 1866, 12,241. It was formerly the seat of a bishop, has a Gothic cathedral, a college, a public library, and large manufactories of essences and perfumes, soap, and silk goods. In the vicinity are quarries of marble and alabaster, and extensive olive groves.

**GRASSES**, plants of the natural order *gramineæ*, one of the most extensive in number of species and individuals, and one of the most important in its relation to man. The stem (culm) is jointed, sometimes solid, but usually hollow, and closed at the joints (nodes); from each joint rises a leaf stalk which is broad and envelops the stem, called the sheath (vagina), which with few exceptions is split upon one side for its whole length; at the apex of the sheaths are borne the leaves, which are alter-

nate, the blade (lamina) usually narrow, and with parallel veins; where the blade and sheath join is a small membranous appendage, the ligule, which is sometimes represented by a fringe of hairs. The flowers are arranged at the summit of the stem in strict spikes, racemes, or loose panicles, and are in spikelets, which consist of one or numerous flowers (florets). The

FIG. 1.—Phleum, spikelet.

parts of the flowers are chaffy, usually green when young and becoming straw-colored at maturity, and are described collectively as glumaceous (Lat. *gluma*, a husk), a term also applied to the flowers of some allied families. In structure the flowers present some very complex forms, while that in the more common species is exceedingly simple, and may be readily understood by an examination of the common red-top, a species of *agrostis*, or timothy (*phleum*), to be found almost everywhere. A single spikelet of either of these will be found, as in the engraving of *phleum*, to consist of two concave scales called glumes, one placed slightly above and within the other; within these are the floret, consisting also of two scales, and the palets, the upper and inner of which is more or less covered by the outer, and usually smaller and of more delicate texture; the essential parts of the flower are within and protected by the palets; the stamens, one to six (usually three), have slender filaments with anthers attached by the middle (versatile); pistil one, with a one-celled, one-ovuled ovary crowned by two (rarely three) styles, the stigmas of which are feathery or hairy; the ovary in ripening becomes a grain (caryopsis), which consists of the usually adherent pericarp (the hull), within which is the seed proper, consisting of a small embryo situated at the base and on the outside of a floury albumen;

FIG. 2.—Aira, spikelet.

at the base of the pistil are situated one or two minute scales (lodiculæ), which are usually so small as to escape the notice of a careless observer, but in some genera are as long as the ovary. This is the general structure of one-flowered grasses, but it is varied in different genera by the suppression of the upper palet, or even by the absence of both glumes, and the prolongation of the apex of one or both glumes or the lower palet into a bristle-like appendage, the awn. In the many-flowered grasses, of which hair grass (*aira*) will serve as a familiar illustration, there are two glumes, and within these two to several florets placed one above another upon a short axis (rachis), all of which except the upper one contain stamens and a pistil; the uppermost floret in the oat and in many other many-flowered grasses is neutral or imperfect; the lower palet in the oat is strongly many-nerved, and bears below its apex a strong and twisted awn. The nu-

FIG. 3.—Poa, spikelet.

FIG. 4.—Anthoxanthum, spikelet.

merous species of *poa*, including the meadow grasses, June grass, blue grass, &c., afford examples of many-flowered grasses in which the spikelets are compressed, the palets without awns, and more or less clothed with cottony hairs. The suborders of the family and the genera are founded upon various modifications of a very simple structure, some of which have been here indicated. In the sweet-scented vernal grass we have another modification; this grass appears to be one-flowered, but it is really three-flowered, with the upper and lower florets abortive and appearing one on each side of the perfect one as an awned empty palet. In barley (*hordeum*) and wheat (*triticum*) the spikelets are sessile in the excavations of a zig-zag stem or rachis; in the barley the spikelets are one-flowered, only the central one sometimes being fertile, as in two-rowed barley, and at others all three being fertile, when the spike or head becomes six-rowed, and the glumes are placed upon the side of the spikelets opposite the stem and form a bristle-like involucre. Grasses are annuals or perennials, and in some of the perennial species the root stock runs for a long distance underground, as in the couch grass, or "quack" (*triticum repens*), which often becomes a serious pest to the cul-

tivator. The root stocks, improperly called roots, possess great vitality, and if broken in the processes of cultivation, each joint is capable of producing a new plant.—The genera and species of grasses are numerous, and are estimated to form  $\frac{1}{25}$  part of all known flowering

FIG. 5.—Sweet-scented Vernal Grass (*Anthoxanthum odoratum*).

FIG. 6.—Red-top (*Agrostis vulgaris*).

FIG. 7.—June or Blue Grass (*Poa pratensis*).

plants; they are found in all parts of the world. In temperate regions they are usually of low growth and carpet the surface of the earth, but toward the tropics they are taller and more tree-like in habit. The extremes in stature are striking when we contrast the minute *Phippsia* of the arctic regions, only an inch in height, with the tropical bamboo, which elevates its stem, strong enough to serve for a mast, to the height of 60 ft. The grasses are by far the most useful of all plants, the order including wheat, barley, oats, rye, maize, rice, millet, guinea corn, and sugar cane, besides numerous less known grains which furnish breadstuffs to aboriginal people in various parts of the world, and many species used for animal food in the form of hay. In enumerating the useful qualities and harmless character of grasses, an exception has been made in the case of darnel (*lolium temulentum*), which has long had the reputation of producing a poisonous grain; but, as will be seen under DARNEL, this is doubted. Aside from furnishing food, the economical uses of the grasses are many; some of the most important of these are given under BAMBOO; other grasses furnish materials for mats, cordage, the plaiting of hats, &c. One of the sources of paper stock has within a few years been found in the esparto grasses, *tygeum sparteum* and *stipa tenacissima*, of the shores of the Mediterranean. Some species, as the sand reed of our coasts, and especially the tussock grass (*dactylis cespitosa*) of the Falkland islands, are of essential service in retaining the blowing sands. Different genera

have species which are highly fragrant; the sweet-scented vernal grass (*anthoxanthum odoratum*) has a grateful vanilla-like odor, and to its presence is due the fact that the new-mown hay of the older states is so much more fragrant than that in more recently settled localities, where this grass has not yet become naturalized. Seneca grass or holy grass (*hierochloa borealis*), a native species, has a still more marked odor. Two or more species of *andropogon* furnish the oil-of-lemon grass or citronelle, used in perfumery; and the *vetiver* of the French comes from another species of the same genus.—*Permanent Meadow and Pasture Grasses*. The number of grasses sown by American farmers is limited; the common practice being to sow one or two sorts together with clover, mow it for hay for one or two

years, and then use the field for pasturing until the land is required for cultivation. They rarely sow grass expressly for making a permanent pasture; and as the grasses best for hay are not those most suited to grazing, our pastures are of an inferior character compared with

those of England. Timothy (*phleum pratense*) stands at the head of the hay-making grasses. (See TIMOTHY.) Next in order is red-top (*agrostis vulgaris*), also called in different localities fine-top, Rhode Island bent, Borden's grass, and in Pennsylvania and southward herd's grass, a name which in New York and New England is exclusively applied to *phleum* or timothy; it was formerly called English grass. It

FIG. 8.—Orchard Grass (*Dactylis glomerata*).

grows from 1 to 2 ft. high, according to situation, and has a slender open panicle of small one-flowered spikelets, the reddish color of which suggested its best known common name. It varies greatly with the character of the soil, but in no case yields as largely as tim-

othy, and its great value is in its permanence as a pasture grass. White-top (*agrostis alba*) often appears spontaneously in pastures, and is readily distinguished from red-top by its greenish white flowers; agriculturists are not agreed as to its value. Orchard grass (*dactylis glomerata*) is next in importance, as it is valuable for hay, and especially so for pasturage, and it will grow better than most other grasses in the shade of trees. It is a rather coarse species, grows 3 and even 5 ft. high, and bears a dense branching panicle, on which its several-flowered spikelets are arranged in crowded, one-sided clusters; it has a tendency to form tussocks, which unfits it for lawns; and for hay or pasturage the seed should be sown very thickly in order to produce a fine herbage. June grass (*poa pratensis*) is the most valuable of the poas; it is also known as smooth-stalked meadow grass, green grass, and Kentucky blue grass. By reason of its creeping root stocks it rapidly forms a dense turf, and is more valued for the pasture than the meadow; but it is used for hay, its after-math or second cutting being heavier than the first. It adapts itself to a wide range of country, and endures extreme cold without injury; it forms a large portion of the best pastures of Europe as well as of this country. Varying greatly in different soils and climates, it has received a number of local names besides those already given. It attains its greatest luxuriance in the limestone regions of Kentucky, where it spontaneously takes possession of the land, or "comes in," as the farmers say. The blue-grass pastures of Kentucky have long been celebrated, and at one time it was supposed that the grass was a peculiar one; but it is now well ascertained that it is only the common June grass growing in a peculiarly genial soil and climate. So variable is this species that the English writers on grasses recognize a half dozen or more named varieties. Other species of *poa* are found in our fields and pastures, the principal of which are the fowl meadow grass or false red-top (*P. serotina*), and the roughish meadow grass (*P. trivialis*), which resembles June grass, but blooms in moist meadows nearly a month later. The tall fescue (*festuca elatior*), though rarely sown, often appears in meadows and pastures; the sheep's fescue (*F. ovina*) and the hard fescue (var. *duriuscula*) grow upon sandy hard soils, and in some localities form the bulk of the sheep pasturage. The tall meadow-oat grass (*avena elatior*) was some years ago overpraised as "the grass of the Andes," and fell into disrepute; but it has latterly been regarded with more favor, and is valued by those who have cultivated it. Meadow foxtail (*alopurus pratensis*) is highly prized as a pasture grass in England, and is sparingly introduced into this country; it has a resemblance to timothy, but the structure of the flowers is different, and it is much more soft to the touch. Sweet-scented vernal grass, the odor of which has been already mentioned, is common in

meadows, though it is rarely sown; while it adds to the enjoyment of the haying season, it is of no agricultural value. Under the name of rescue grass, a plant was much lauded in Europe a few years ago as something that would rescue fields from sterility and farmers

FIG. 9.—Buffalo Grass (*Buchloë dactyloides*).  
1. Male. 2. Female.

from ruin; the seed was sold as *bromus Schraderei*, but it is probably a form of *bromus unioloides*, and of little value. Italian rye grass is a form of the variable *lolium perenne*, other varieties of which are known as Russell's, Pacey's, and Stickney's rye grasses; it is valuable for hay, pasturage, or soiling, especially on irrigated meadows.—*Annual Grasses*. Among those of this class grown for hay are Hungarian grass (*panicum [setaria] Germanicum*) and Italian millet (*P. miliaceum*), which are often useful in supplementing a short hay crop. The foliage of some of the cereal grains is used for forage, it being cut before the grain ripens and cured like hay; oat, rye, and maize are those principally grown.—*Grasses of Spontaneous Growth*. Bermuda grass (*cynodon dactylon*) is a native of Europe, Asia, and Africa, and is abundantly naturalized south of Pennsylvania. It is a low, much-branched perennial, creeping extensively by root stocks, and soon forms a dense mat that completely excludes all other vegetation. In most localities it is regarded as a troublesome weed, but it is of great value where other grasses will not grow for pasturage, and even for hay; in this country, at least, it is not known to perfect seed. Buffalo grass (*buchloë dactyloides*), in the prairies west of the Mississippi, extends from the British possessions to Mexico, and is the support not only of buffalo and deer, but the animals of the recent settler; it is one of the few examples of a diocious grass, and the male and female plants are so unlike in their flowering parts that until within a few years they were regarded as belonging to distinct

genera; the pistillate or female flowers are enclosed by a bur-like woody involucre; it runs extensively by stolons, and forms a dense turf, the foliage of which is but a few inches high. Mezquite grass is often mentioned by travellers in the far southwest; like other local names in new countries, this is applied to quite different plants; it seems to be given to whatever grasses grow in the region of the mezquite tree, and species of *aristida*, *bouteloua*, and even the buffalo grass, have this name given to them by different persons. Grama grass is also praised by those who visit Spanish American countries, and comprises a number of species of *bouteloua*. Another indefinite name of travellers is "bunch grass," given to any kind that forms clumps or tufts; festucas, *boutelouas*, *triticums*, and *eriacoma* all bear this name.—*Grasses regarded as Weeds*. One of the most troublesome weeds of the farmer and gardener is couch grass (*triticum repens*), already mentioned. Chess or cheat (*bromus secalinus*) is a pest of the grain fields, often so abundant from unclean seed as to induce ignorant farmers to believe that wheat really turns into chess. Dogs-tail or wire grass (*cleusine Indica*) is a common weed in the streets of towns and villages, and encroaches upon the farms near them. Barnyard grass (*panicum crus-galli*) is common in waste places, and where the soil is rich grows with great luxuriance, but being an annual is easily subdued. The crab or finger grass (*panicum sanguinale*) is late in summer one of the most annoying of the gardener's pests, as it roots at every joint, and unless eradicated when very young is troublesome.—*Marsh Grasses*. Along the margins of rivers, especially where salt and fresh water meet, there are often wide tracts covered with verdure and known as meadows or marshes. When the growth is sufficiently fine these meadows are mowed, and the product, known as marsh hay or salt hay, is largely used for bedding animals and for mulching. Often a large share of this hay consists of grasses, but frequently it is made up of rushes and sedges; a small rush (*juncus Gerardi* and perhaps others), called "black grass," often covers large tracts. Among the grasses proper found in such localities are species of *spartina*, *glyceria*, and *phragmites*.—*Ornamental Grasses*. Several tropical grasses are grown as greenhouse plants, and in late years the taste for cultivating the hardier kinds in the open border has greatly increased. Some of these, like *erianthus Ravennæ* and the pampas grass (*gynerium argenteum*), are grown for their stately appearance; their flower stalks grow to the height of 12 ft., and their long leaves form large clumps of graceful outline. Other species are cultivated for the beauty of their flowers, which are dried for making ornamental bouquets. In some of the horticultural establishments of Germany bouquets of dried grasses are an article of export.—Very many kinds of grass not here enumer-

ated are more or less well known, the more important of which are treated in separate articles, as CANARY GRASS, FEATHER GRASS, MILLET, REED, &c. Many plants commonly called grasses do not belong to the grass family. In some agricultural works, clover, lucerne, sainfoin, and other forage plants are incorrectly classed as grasses; these will be found under their proper titles.—The most complete general scientific treatises upon grasses are Kunth's *Enumeratio Plantarum* (5 vols., Stuttgart, 1833-'50) and Steudel's *Synopsis Graminearum* (Stuttgart, 1855). The species east of the Mississippi are described in Gray's "Manual of the Botany of the Northern United States" (New York, 1867) and Chapman's "Flora of the Southern United States" (New York, 1860); those of the far western portions of our territory are scattered through various reports and memoirs. Flint's "Grasses and Forage Plants" (Boston, 1867) is the principal American work upon the agricultural grasses.

**GRASSHOPPER**, a name properly applied to orthopterous insects of the family *locustadæ*. Some European entomologists assign the generic name *locusta* to the grasshopper; the *sauterelles* of the French include both locusts and grasshoppers; great inconvenience has arisen from this confusion of names, which will be avoided by calling the grasshoppers *locustadæ*, and the locusts *acrydii*. The *locustadæ* are characterized by having long antennæ, four joints to all their feet, wing covers sloping downward at the sides of the body, and the end of the abdomen in the females provided with a projecting sword-shaped piercer; the jaws are formed for mastication; the upper wings are thick and opaque, overlapping a little on the back, this portion forming a long triangle, traversed in the males by strong projecting veins, between which are thin, transparent, membranous spaces; the under wings are thin and folded in plaits like a fan; they undergo a partial transformation, the larvæ and pupæ being active, voracious, and wingless; they are injurious to vegetation in all their forms. The males emit a shrill sound produced by the friction of the overlapping portions of the wings, intensified by the vibration of the air contained in the internal air sacs, and its action upon a complicated series of valves and membranous plates about the origins of the wings and legs. Most grasshoppers are of a green color, more or less resembling the leaves upon which they feed; they are more active by night than by day; when taken, they emit from the mouth a dark-colored fluid, known by every school boy as "molasses;" they do not associate together, nor migrate from place to place in large numbers, as do the locusts proper. Some live upon grass and herbaceous plants, and the females lay their eggs in the ground in holes made by their nearly straight piercers; the eggs are elongated, ellipsoidal, very numerous, from one fourth to one fifth of an inch long, and

covered with a thin varnish-like film. Others live upon trees and shrubs, like the katydid; their wings and covers are broader, and they deposit their eggs on the branches of trees in regular rows, having shaved off the bark with their short and curved piercer. The legs are

Oblong Leaf-winged Grasshopper (*Phylloptera oblongifolia*).

three pairs, the posterior being much the longest and capable of performing the jumps whence these insects derive their name; they all end in elastic hooks. The flight of the grasshopper is short, unsteady, and noiseless, compared with that of the locust. The American katydid (*platyphyllum concavum*, Harris) will be described under that title. Other native grasshoppers are: 1. The spotted wingless grasshopper (*phalangopsis maculata*, Harris), pale yellowish brown, with small light spots on the darker back, smooth and shining, with arched back, from half an inch to about an inch long; it is common, under stones and sticks in the woods, has the short thick body and stout hind thighs of a cricket, and is entirely destitute of wings. 2. The oblong leaf-winged grasshopper (*phylloptera oblongifolia*, De Geer) is of a brilliant green, with very delicate wings, the under extending far beyond the upper; the body is only about an inch long, but to the end of the wings it often measures three inches; in its perfect state it is found upon trees in September and October;

Narrow-leaved Grasshopper (*Phaneroptera angustifolia*).

during flight it makes a whizzing noise. 3. The curved-tailed grasshopper (*P. curvicauda*, De Geer), of the middle and southern states, is a larger species, with wing covers broadest in the middle. 4. The narrow-leaved grasshopper (*phaneroptera angustifolia*, Harris) is green,

with wing covers rounded at the tips and shorter than the wings, a short bent piercer, and in the male a long tapering projection from the under side of the body; it measures in the body three quarters of an inch, and to the end of the wings about an inch and three quarters; it comes to maturity early in September. 5. The common meadow grasshopper (*orchelimum vulgare*, Harris), so numerous near the end of summer at different ages, is of a general green, with a brown stripe on the top of the head and thorax; it measures at maturity about three quarters of an inch to the end of the body, and a quarter of an inch more to the end of the semi-transparent wing covers; the shrilling organs consist of a transparent glassy spot in the overlapping portion of each wing cover, which is larger and stronger than in other grasshoppers; the hindmost thighs are smooth, there are two spines on the middle of the breast, and the antennae extend beyond the end of the hind legs. 6. The sword-bearer grasshopper (*conocephalus ensiger*, Harris) has the head conical, extending to a blunt point between the eyes, and a long, straight, sword-shaped piercer; it measures an inch to the end of the body, and

Common Meadow Grasshopper (*Orchelimum vulgare*).

an inch more to the end of the wing covers; it is pale green, with whitish head, and pale brownish green legs and abdomen.—The young grasshopper comes from the egg without wings; passing through several moultings, the body increases and little stump-like wings appear; the wings gradually become longer with each change of skin, the insect hopping about by means of its muscular hind thighs; after ceasing to grow, the wings are perfect organs of flight, and the grasshopper enters upon its short life; the song by degrees becomes less, the body shrivels, the legs wither, the appetite ceases, and in three or four weeks the whole number are dead. The larvæ remain in the earth or wherever the eggs are deposited all winter, and are hatched in the spring; they are voracious as larva, pupa, and perfect insect, and in all these stages are eagerly devoured by fowls, especially turkeys.—The green grasshopper of Europe (*L. viridissima*, Latr.) is two inches long, of a fine green without spots. The *L. verrucivora* (Fabr.) is green, with the wing covers spotted with brown and black; it bites severely, and the Swedes submit their warts to its mandibles, asserting that after its bite the warts quickly disappear.

There are many other species in different parts of the world, but none merit attention for their destructiveness in comparison with the locusts; war is rarely waged against grasshoppers, as their natural enemies, birds, domestic fowls, and sand wasps, keep them down in proper limits.

**GRASSMANN, Hermann Günther**, a German mathematician, born April 15, 1809, died Sept. 26, 1877. His father was professor of mathematics in the gymnasium of Stettin, and the author of several mathematical text books. Hermann studied theology and mathematics, and from 1834 to 1852 was a teacher in the *Otto-Schule* in Stettin, when he succeeded his father as professor of mathematics in the gymnasium. In 1844 he published the first part of *Die Wissenschaft der extensiven Grösse, eine neue mathematische Disciplin*. This part also bore the special title *Die lineale Ausdehnungslehre, ein neuer Zweig der Mathematik, dargestellt und durch Anwendungen auf die übrigen Zweige der Mathematik, wie auch auf die Statik, Mechanik, die Lehre vom Magnetismus und die Krystallonomie erläutert*. In the preface to this work he gave a short account of his discovery, and declared his intention to make its development and application the chief object of his life. He further developed his theory in *Geometrische Analyse* (1847), which obtained the prize offered by the Prince Jablonski scientific society of Leipsic, and in articles in Crelle's mathematical journal treating the higher classes of curves. In 1853 Cauchy published in the *Comptes rendus* of the French academy a method of resolving algebraical equations and other problems by means of certain symbolical quantities, which he called *clefs algébriques*. The method was identical with that employed by Grassmann, and the latter immediately addressed a "claim of priority" to the academy. A committee was appointed to examine the question, but it never made any report, and Cauchy abruptly broke off the publication of his articles. In 1862 Grassmann completed the development of his theory by publishing *Die Ausdehnungslehre vollständig und in strenger Form bearbeitet*. This work is in strict mathematical form, after the model of Euclid's Elements, consisting almost entirely of propositions and demonstrations. In it he develops the connection of his theory with every branch of mathematics, from arithmetic to the integral calculus, and discusses its application to geometry. The profoundly metaphysical character of his first work and the exceedingly abstract form of the last, together with the total absence of all geometrical figures and all simple illustrations, have very much retarded the progress of his doctrine among professed mathematicians, and have prevented its comprehension by any others. It has many striking analogies to the quaternions of Sir William Rowan Hamilton. There can be little doubt that the theory of Grassmann, or one essentially the same, and only differing

somewhat in form, will in time supersede the whole system of analytical geometry as founded by Descartes and so greatly developed by the labors of subsequent mathematicians. Grassmann was a frequent contributor to the leading scientific journals of Germany, and published text books on various branches of science. He had an extensive knowledge of languages, and published a work on the German names of plants (1870), and a Sanskrit dictionary of the *Rig Veda*, with a German translation of the work (1873-'5).

**GRASS TREE**, one of the English names given to plants of the genus *xanthorrhoea*, which are also called grass-gum trees and black-boys. They belong to the order *liliaceae*, and are especially distinguished by their crowns of long, pendulous, grass-like leaves, from the centre of which arises a long stem bearing at its summit a dense flower spike looking somewhat like a large cat-tail (*typha*). Some species have very short stems, while others have trunks 6 to 18 ft. high, which, with their singular tufts of leaves, form a striking feature in the Australian landscape. *X. arborea*, *X. australis*, both arborescent, and *X. hastilis*, nearly stemless, are the best known species, as they are the principal ones in cultivation as ornamental greenhouse plants. Two resins obtained from these plants have been known for some time; one is yellow and called Botany Bay resin and gum acaroides, and the other red, resembling dragon's blood, and known as black-boy gum. They are aromatic, contain cinnamic and benzoic acids, and have the general properties of the balsams proper. No important use seems to have been found for these products.

**GRATIAN** (AUGUSTUS GRATIANUS), emperor of Rome, born in Pannonia in 359, slain at Lugdunum (Lyons) in 383. His father, Valentinian I., bestowed upon him the title of Augustus in his childhood, but when he died in 375 the officers of the army compelled Gratian to give his half brother Valentinian II., then a young child, a share in the western empire, the East being in the hands of his uncle Valens. Gratian received Gaul, Spain, and Britain, and reigned over Italy, Illyricum, and Africa as guardian of his brother. Great severity marked the beginning of his reign. When the East was attacked by the Goths, Gratian was delayed in aiding his uncle by another incursion of barbarians from the north; and when he finally marched to his rescue, he received the news of his defeat and death (378), which made him the ruler of both parts of the empire. In the next year he ceded the East to the younger Theodosius. Several wars with barbarous tribes on the Rhine and Danube were successfully terminated, and Gratian, who is praised by both Christian and pagan historians as just, moderate, and virtuous, now enjoyed a few years of repose at his residence in Milan, where he became the friend of St. Ambrose. By the confiscation of the property of the temples and the abolition of the privileges of

the priests, he greatly contributed to the downfall of paganism. A military rebellion, which broke out in Britain under Maximus, and spread to Gaul, deprived him of his throne and life.

**GRATIOT**, a central county of the S. peninsula of Michigan, drained by Pine and Maple rivers; area, 576 sq. m.; pop. in 1870, 11,810. It has an undulating surface and a productive soil, partially covered with pine timber. The chief productions in 1870 were 127,111 bushels of wheat, 81,655 of Indian corn, 64,923 of oats, 95,354 of potatoes, 306,436 lbs. of butter, 44,903 of wool, and 13,297 tons of hay. There were 2,072 horses, 3,288 milch cows, 4,748 other cattle, 11,536 sheep, and 4,890 swine; 4 flour mills, and 13 saw mills. Capital, Ithaca.

**GRATRY**, *Auguste Joseph Alphonse*, abbé, a French theologian, born in Lille, March 30, 1805, died at Montreux, Switzerland, Feb. 6, 1872. In 1841 he was appointed director of the college of Ste. Barbe, Paris, and in 1846 chaplain of the superior normal school. In 1851 a controversy with his colleague, M. Vacherot, led to their resigning their positions. Gratry now founded, in conjunction with the abbé Petetot, a society of priests called "Oratory of the Immaculate Conception," and devoted himself in an especial manner to the conversion and instruction of the Parisian youth. In 1861 he was appointed by Bishop Dupanloup vicar general of Orleans, and in 1863 became professor of moral theology in the Sorbonne. On the publication of his *Cours de philosophie* (1855-'7) he was hailed as a valuable auxiliary by the ontologists. In 1864 he vehemently attacked Renan and the whole rationalistic school; and in 1867 he was elected a member of the French academy, chiefly, it is thought, in consideration of his three works, *Paix, méditations historiques et religieuses* (1862), *Sources, conseils pour la conduite de l'esprit* (2 vols. 8vo, 1861-'2), and *Commentaires sur l'évangile de Saint Matthieu* (1863). In 1869 his connection with Père Hyacinthe and the "International League of Peace" drew on him the censure of the superior of the Oratory, from which body he thereupon withdrew. In 1870 he published two letters on the position of parties in the council of the Vatican, which he retracted in December, 1872, in a letter to the new archbishop of Paris, Guibert. His principal works, besides those above mentioned, are: *Philosophie du Credo* (1861); *Jésus-Christ, lettres à M. Renan* (1864); *Les sophistes et la critique* (1864); *Henri Perreye* (1866); and *La morale et la loi de l'histoire* (2 vols. 8vo, 1868).

**GRATTAN**, *Henry*, an Irish statesman and orator, born in Dublin, July 3, 1746, died in London, May 14, 1820. His father, a barrister and a Protestant, was for many years recorder of Dublin and also a member of the Irish parliament. Henry entered Trinity college, Dublin, in 1765, and graduated with distinction in 1767, after which he removed to London and became a student in the Middle Temple. His admiration for the eloquence of Lord Chat-

ham determined him to become an orator. He was admitted to the Irish bar in 1772, and in 1775 entered the Irish parliament as representative of Charlemont. He at once joined the opposition, and united with Flood and the leading patriots of the day in endeavoring to obtain free trade for Ireland. On April 19, 1780, he introduced and supported with great eloquence the famous declaration of right, denying the power of the British parliament to legislate for Ireland. His motion was lost, but he became the idol of the Irish people. He fired their national spirit, and through his influence the volunteer bands assembling from all parts of Ireland were swelled to the number of 80,000. These volunteers held a meeting at Dungannon in February, 1782, and passed unanimously the resolution drawn up by Mr. Grattan, that "a claim of any body of men, other than the king, lords, and commons of Ireland, to make laws to bind this kingdom, is unconstitutional, illegal, and a grievance." On April 16, 1782, he repeated in the house of commons his motion for a declaration of Irish right. The resolutions were carried by an overwhelming majority. Mr. Fox decided instantly to yield, and brought in a bill for repealing the act (6 George I.) by which the British parliament claimed the right to bind Ireland by British laws. Grattan was now the most popular man in Ireland, and parliament proposed to vote him £100,000 "as a testimony of the national gratitude for great national services." It was only at the earnest request of his friends that he agreed to accept half the amount. During the following sessions of parliament he found a bitter and sarcastic opponent in Flood, who encouraged the story which had been set on foot, that Grattan having received his pay had ceased to be a patriot. In 1785, by his opposition to the propositions regarding the trade between Great Britain and Ireland, known as Ord's propositions, he regained his popularity. In 1790 he was returned to parliament by the city of Dublin. On the arrival in 1795 of Earl Fitzwilliam, he associated himself with that nobleman in originating plans for the peace and prosperity of his native country. After the earl's recall dissensions arose, and the society of United Irishmen proposed to form a republic, and opened intercourse with France to gain help. Grattan, after advising conciliatory measures in vain, withdrew from parliament. When Mr. Pitt proposed measures for uniting Great Britain and Ireland, he again obtained a seat in parliament as member for Wicklow, for the express purpose of opposing this measure; but when the union had been effected he entered the imperial parliament as representative of the borough of Malton in 1805, and of Dublin in 1806. In opposition to the corporation of his native city, he advocated Catholic emancipation, and undertook a journey to London, while in feeble health, to present a petition from the Catholics to the house of commons. When

his friends remonstrated, he replied that he would be happy to die in the discharge of his duty, and he did in fact sink under the exertion soon after his arrival. Grattan was below medium stature and exceedingly unprepossessing in appearance. His oratory was impassioned, and he was often entirely overcome by his subject. His private character was without a blemish. His speeches were edited by his son Henry Grattan (4 vols., London, 1822), and a selection from them by D. O. Maddyn (Dublin, 1845). A volume of his miscellaneous works appeared in 1822, and his "Life and Times" by his son in 1839-'46 (5 vols., London).

**GRATTAN, Thomas Colley**, an Irish novelist, born in Dublin in 1796, died in London, July 4, 1864. He studied law, and procured a commission in the army, but renounced both professions on his marriage, and afterward resided in France. At the age of 25 he published "Philibert," a metrical romance, which was a complete failure. He next became a contributor to various magazines and reviews, and in 1823 published in two volumes the first series of "Highways and Byways." A second series appeared in 1824, and a third in 1827, each in three volumes. Establishing himself in Brussels, he wrote a number of works, of which "Traits of Travel" (3 vols., 1829), "The Heiress of Bruges" (4 vols., 1830; new ed., 3 vols., 1834-'49), "History of the Netherlands" (1830), "Jacqueline of Holland" (1842), and "Legends of the Rhine" (3 vols., 1849), are the best known. Having actively supported the candidacy of King Leopold in the Belgian revolution of 1830, he was at the request of that sovereign appointed in 1839 British consul to Boston, which office he resigned in 1852, to accept one in the queen's household. His "Civilized America" (2 vols., London, 1859) is a spiteful record of his experiences in North America. His last work was "Beaten Paths" (2 vols., 1862).

**GRATTONI, Severino**, an Italian engineer, born at Voghera, Dec. 7, 1816. After extensive studies, he was from 1845 to 1851 director of an observatory under Plana, and formed the acquaintance of Cavour, who consulted him on public works, especially on the project of piercing Mont Cenis. Grattoni, being elected to the chamber of deputies, supported Cavour's policy, and was soon called upon, together with Sommeiller and Grandis, to devote himself to the Mont Cenis tunnel scheme. While Sommeiller supplied the chief inventive power, and Grandis a sound judgment on theoretical questions, Grattoni, by his skill, energy, and perseverance, became the organizing genius of the work, which was completed in September, 1871.

**GRATZ**, or **Grätz**, a town of Austria, capital of the province of Styria, on the Mur, 90 m. S. S. W. of Vienna; pop. in 1870, 80,732. It consists of the town proper, which is on the left bank of the river, and is fortified, and of four suburbs connected with the town and

with each other by bridges. The chief public buildings are a magnificent Gothic cathedral erected by the emperor Frederick III. in 1456; St. Catharine's chapel, built as a mausoleum by Ferdinand II., whose remains repose here; the Landhaus, where the diet of Styria holds its sessions; the old palace of the Styrian dukes; the university, founded in 1586, subsequently abolished, restored in 1827, and having in 1873-'4 70 professors and 975 students, with a library of about 70,000 volumes and 7,500 MSS.; the Johanneum, an institution established in 1811 by Archduke John for the encouragement of the arts, sciences, and manufactures of Styria; and the refectory or *convicte*, the largest building in Gratz, formerly belonging to the Jesuits, but now a collegiate school. It is the seat of a Roman Catholic bishop, who bears the title of bishop of Seckau. There are 22 Catholic churches, a Protestant church, and 10 convents. The principal manufactures are cotton, woollen, silk, hardware, leather, and paper.

**GRAUBÜNDEN**, or **Graubündten**. See GRISONS. **GRAUBENZ**, a fortified town of Prussia, in the province of West Prussia, on the Vistula, 60 m. S. of Dantzic; pop. in 1871, 15,559. It has a Protestant and five Roman Catholic churches, a convent, a gymnasium, a normal school, and two hospitals. There are manufactories of cloth, tobacco, and carriages, several breweries and distilleries, a considerable trade in cloth and corn, some shipping, and four annual fairs. The fortress was built by Frederick the Great, and became famous in 1807 for its brave defence by Courbière.

**GRAUN, Karl Heinrich**, a German composer, born in Wahrenbrück, Saxony, in 1701, died in Berlin, Aug. 8, 1759. He studied music in Dresden, subsequently became tenor and composer to the opera house in Brunswick, and in 1740 was appointed by Frederick the Great his chapelmaster, a position which he occupied during the remainder of his life. He was the author of 30 operas, and an immense number of cantatas and miscellaneous pieces. His best works are the oratorio *Der Tod Jesu*, and his *Te Deum*.

**GRAVE CREEK**. See MOUNDSVILLE.

**GRAVEL**, small stones, commonly intermixed with sand, and sometimes with clayey or calcareous earth. Such a mixture constitutes the principal portion of the drift formation; and where this prevails, the surface of the country is often covered to unknown depths with deposits of sand and gravel. It forms hills throughout New England, and nearly the whole of Long Island is covered with it. (See DILUVIUM.) It is of more recent formation wherever rocks, especially the granitic, are comminuted by joint action of atmospheric and fluvial agents, and their materials are gathered in the bed and banks of swift running streams. On the beaches of seas and lakes, the gravel, piled up in beds of coarse pebbles and washed clean of sand and all earthy matters, is called shingle.

**GRAVEL**, substances consolidated and precipitated from the urine within the body, in certain diseased conditions of the system, differing from calculi by their small size, and generally voided without surgical interference. (See CALCULI.) The appearance of gravel is important as evidence of a disposition to calculous deposits, and as indicating the proper treatment. When the disposition exists, a tendency which obstructs the passage of urine favors the precipitation of gravel. There are three kinds of gravel, as there are three principal forms of calculi, viz.: the lithic, the oxalic, and the phosphatic. Lithic or uric acid, a highly nitrogenous compound, exists normally in the urine in combination with soda; if the urine be abnormally acid, the lithic acid will be precipitated in a crystalline form, constituting the lithic or red gravel; lithic acid when pure is white, but in human urine it assumes the tint of its coloring matter, which causes it to look like Cayenne pepper. The urine containing this gravel is generally acid, high-colored, scanty, but clear; in what is called a "fit of the gravel," this acid is precipitated in large quantity, accompanied by fever, pains shooting from the loins to the bladder, frequent and scalding micturition, &c. The causes which predispose to the excessive formation of lithic acid have been detailed in the article GOUT, with which disease gravel is intimately connected; it will be sufficient to say here that the use of highly nitrogenous food and stimulating drinks, and sedentary or slothful habits, are very likely to induce both gout and lithic acid gravel. Though not unfrequently occurring in children, gravel is most common between the ages of 40 and 65; it is comparatively rare in warm climates, or in persons living chiefly on vegetable food. On the principles of Liebig, the great indication for the treatment of the red gravel is to promote the action of oxygen on lithic acid so as to cause its conversion into urea and carbonic acid, and its consequent escape from the system through the urine and the perspiration; in other words, to take in an increased supply of oxygen by exercise in the open air, by preparations of iron, and by the nitro-muriatic acid; to moderate the quantity of highly nitrogenous food, avoiding that containing much starch and sugar, as well as malt and fermented liquors; to secure a healthy action of the skin by suitable clothing and attention to cleanliness; to remove all intestinal obstructions, and to neutralize acidity, if necessary, by the administration of alkalies.—The lithic acid gravel may be regarded as the sign of an inflammatory or congestive habit, but the next form, or the oxalic acid gravel, belongs to an irritable or nervous constitution, and is usually accompanied by a dry skin, dyspepsia, boils, carbuncles in advanced life, and nervous exhaustion or despondency; the urine is transparent, pale greenish yellow, of moderate specific gravity, and free from sediments, but containing minute crystals of oxalate of lime. The

causes of this diathesis are such as produce dyspepsia, nervous debility, and hypochondriac diseases: residence in malarious districts, and unwholesome vegetable food. The treatment is very similar to that for lithic acid gravel, it being remembered that in this case the system craves less oxygen; distilled water is advised in order that lime may not in this way be introduced into the system and endanger the formation of mulberry calculi; alkalies, with ammonia, tonics, and the mineral acids, are required according to circumstances. Oxalate of lime deposits, however, are usually much less abundant and less irritating than those of uric acid, and, as a general rule, are less important indications of an unhealthy state of the system. The white gravel may be either the ammoniaco-magnesian phosphate or the phosphate of lime, or the mixture of the two. The earthy phosphates are naturally held in solution by the acid reaction of the urine; and when this is neutralized or replaced by an alkaline reaction, these phosphates are precipitated in the form of a white amorphous powder. If the urine become ammoniacal, a new compound is formed, namely, the triple phosphate of magnesia and ammonia. This substance has the form of three-sided prismatic crystals, sometimes large enough to be distinguished by the naked eye. The phosphatic diathesis is generally seen in pale and weak persons, complaining of nervous exhaustion, as Dr. Prout maintains, on account of the great consumption of phosphorus in nervous diseases; it may be produced by excessive fatigue of body or mind, intense study, unwholesome food, weakening medicines, and chronic urinary affections. The treatment should consist of tonics.

**GRAVELINES** (Flem. *Gravelinghe*; Ger. *Gravelingen*), a fortified seaport town of France, in the department of Le Nord, near the mouth of the Aa, 10 m. W. S. W. of Dunkirk; pop. in 1866, 6,510. It contains a handsome market place, a church built in the 16th century, and a modern town hall, and has an extensive coasting trade and active fisheries. Cheese, butter, and eggs are exported; sail cloth and linens are manufactured, and there is some ship building. The town was founded in 1160 by Count Thierry of Alsace and Flanders. A famous victory was achieved here by the Spaniards under Egmont over the French under the marshal de Thermes, July 13, 1558. It was annexed to France by the treaty of the Pyrenees (1659). Louis XIV. had new fortifications constructed, designed by Vauban.

**GRAVELOTTE**, a village of Germany, in Alsace-Lorraine, on the Moselle, 8 m. W. of Metz; pop. 700. Here on Aug. 18, 1870, the first and second German armies, commanded by Gen. Steinmetz and Prince Frederick Charles under King William in person, obtained a great victory over the French under Marshal Bazaine. The battle of Gravelotte decided the fate of Metz. It was probably the bloodiest and the

most hotly contested of the war, the loss of the Germans being about 20,000 in killed and wounded, and that of the French, who occupied superior positions and acted on the defensive, about 13,000.

**GRAVES,** a S. W. county of Kentucky, bordering on Tennessee, and drained by Mayfield creek and Obion river; area, 515 sq. m.; pop. in 1870, 19,398, of whom 2,329 were colored. It is traversed by the Paducah and Memphis railroad. The surface is level and the soil generally productive. The chief productions in 1870 were 96,453 bushels of wheat, 842,445 of Indian corn, 24,424 of oats, 14,952 of Irish and 24,259 of sweet potatoes, 158,380 lbs. of butter, 4,774,195 of tobacco, and 187 bales of cotton. There were 3,935 horses, 2,311 mules and asses, 3,681 milch cows, 4,404 other cattle, 13,876 sheep, and 31,570 swine; 1 woollen factory, and 2 wool-carding and cloth-dressing establishments. Capital, Mayfield.

**GRAVES, Robert,** an English engraver, born May 7, 1793, died in London, Feb. 28, 1873. He was the eldest son of Robert Graves, a noted connoisseur of rare prints, and the grandson of a printseller. Among his latest productions were a series of portraits from the works of Sir Joshua Reynolds and Gainsborough, and his last work was the portrait of Charles Dickens, after Frith.

**GRAVESANDE, Willem Jakob van 's,** a Dutch philosopher, born in Bois-le-Duc, Sept. 27, 1688, died in Leyden, Feb. 28, 1742. He published at the age of 18 an essay on perspective, and a philosophical thesis on suicide. After completing his studies in the university of Leipsic in 1707, he was admitted to the bar at the Hague, where he wrote for the *Journal Littéraire* an examination of Fontenelle's "Geometry of the Infinite," a dissertation on the construction of the air pump, one concerning the force of bodies, in which he embraced the opinion of Leibnitz against that of Newton, and dissertations upon the motion of the earth, &c. In 1717 he was appointed professor of mathematics and astronomy in the university of Leyden, and exchanged his chair in 1734 for that of philosophy, which he held till his death. His philosophical writings are eclectic in character, combining portions of the doctrines of Locke, Descartes, and Leibnitz. His principal works are: *Physices Elementa Mathematica* (2 vols. 4to, the Hague, 1720-'23); *Matheseos Universalis Elementa* (8vo, Leyden, 1727); and *Introductio ad Philosophiam, Metaphysicam et Logicam* (Leyden, 1736-'7).

**GRAVESEND,** a municipal borough, town, and river port of Kent, England, on the right bank of the Thames, 21 m. E. by S. of London; pop. in 1871, 21,183. The principal public edifices are the town hall, parochial church (where Pocahontas is buried), literary institution, and theatre. Ship building is carried on to a considerable extent, but the chief trade arises from supplying outward-bound ships with stores and clothing. Gravesend is the limit of the port

of London; inward-bound vessels stop here for examination by the customs officers.

**GRAVIER, Jacques,** a French missionary in America, died in 1708. Soon after his arrival in Canada, in 1684, he was sent to the Illinois region, where he followed up the labors of Marquette and Allouez among the Kaskaskias and other bands of the Illinois, and became the real founder of the mission, which he directed for many years, meeting much opposition from the medicine men, and receiving at their hands a wound which ultimately caused his death. He compiled a grammar of the Illinois, which was highly esteemed and formed the basis of all subsequent works of the kind. When Iberville began the settlement of Louisiana, the Illinois prepared to go down the Mississippi; but the Kaskaskias, the first to move, were induced by Gravier to halt at the place which now bears their name. He went down to confer with Iberville, and has left a journal of his canoe voyage. He descended again in 1706, and went to Europe. He returned in February, 1708, but must have reëmbarked, as he died at sea in April. Of his writings the following have been printed: *Relation de ce qui s'est passé dans la mission de l'Immaculée Conception au pays des Illinois 1693-'4* (8vo, New York, 1857); *Relation ou Journal du voyage en 1700 depuis le pays des Illinois jusqu'à l'embouchure du Mississipi* (1859); *Lettre sur les affaires de la Louisiane, fév. 23, 1708* (1865).

**GRAVINA,** a town of S. Italy, in the province and 36 m. S. W. of the city of Bari, on a river of the same name, an affluent of the Bradano; pop. about 14,000. It is the seat of a bishop, and has five churches and a gymnasium. It was unsuccessfully besieged by the Saracens in 975.

**GRAVINA, Giovanni Vincenzo,** an Italian jurist, born at Roggiano, Jan. 20, 1664, died in Rome, Jan. 6, 1718. Devoting himself to civil and canon law, he went to Rome in 1689, published several brief works on morals and literature, and in 1695, having collected 15 of his friends in his garden, formed the academy of the Arcadians. In 1699 he was appointed professor of civil law in the college of La Sapienza, and in 1703 of canon law. He soon after published his works on the "Origin of the Civil Law" and on the "Roman Empire." A schism took place in 1711 in the academy of the Arcadians, and Gravina and his friends withdrew and founded the Quirina academy. He was the adoptive father of Metastasio.

**GRAVITY,** or **Gravitation** (Lat. *gravitas*, weight), in physics; the tendency of bodies toward each other or toward a centre of attraction. In the article **ASTRONOMY** we have considered the history of the discovery of the great law of gravitation, and have sketched the application of the law to elucidate a variety of problems of interest connected with the motions of the celestial bodies; in the article **EARTH** we have considered the application of this law to determine the mass and figure of the earth; and in dealing with the lunar mo-

tions, we shall have to consider more in detail the perturbative action of gravity. In the present place, therefore, we limit ourselves to the consideration of terrestrial gravity in its effects on bodies upon or close to the surface of the earth. There are two ways in which the action of gravity at any station can be measured. We can examine its effect in causing bodies to have weight; this is the statical action of gravity. Or we can consider its effect upon bodies let fall to the earth; the velocity acquired in a given time affords the means of estimating this, the dynamical action of gravity. For many reasons the latter is the more convenient method of measuring it. The balance, the readiest and most trustworthy method of weighing bodies, obviously fails us when the measurement of the effect of gravity is in question, since the weight and the body weighed are equally under its influence. Nor can the spring balance be trusted for comparing the action of gravity at different stations, even though the utmost precaution has been exercised in freeing the instrument from the disturbing influences of differences or changes of temperature. No difficulties of this sort attend the dynamical method of measuring gravity; because bodies of different specific gravity, or the same body in different conditions of temperature, will fall (*in vacuo*) through the same space in the same time under the influence of gravity. The resistance of the air may indeed be neglected where the difference of specific gravity is very small, as in the case of the same mass of metal at different temperatures. The method of measurement here indicated is however comparatively rough. It was that used by Galileo to determine the time of fall of bodies under the influence of gravity, and by means of the mechanical arrangement called Atwood's machine it can be applied to obtain a fair approximation to the velocity acquired in a given time. But for all delicate researches the pendulum is employed. It is known that when a pendulum swings in a short arc its rate of swing is appreciably constant (though the small arc should vary), and depends on the length and figure of the pendulum and the action of gravity. Contrivances have been invented by which the true rate of swing at any place, for a pendulum of known figure, can be most accurately ascertained. This being effected, it becomes possible to compare the action of gravity at different terrestrial stations.—Gravity varies on the earth's surface owing to two principal causes. In the first place, the earth is rotating, and every point on its surface therefore has a tendency (constantly overcome by gravity) to move in a straight line tangent to the earth's surface. This tendency is commonly called the centrifugal force due to the earth's rotation; an objectionable mode of expression, because no force properly so called is in question. The tendency is mere inertia. If the tendency were the same at all stations, gravity would

be uniformly affected, and no difference would accrue; but the tendency is greatest at the equator, where the motion is most rapid, and diminishes thence to the poles, where it is zero. The action of gravity in producing weight or in causing the fall of a body is obviously diminished by this tendency; and being most diminished at the equator, gravity is there least on this account, and gradually increases toward the poles. It is estimated that, so far as this cause alone is concerned, gravity at the equator should be less than at the poles by  $\frac{1}{289}$  part. But secondly, owing to the same cause (the rotation of the earth), the terrestrial globe is not a perfect sphere, but is compressed at the poles. Hence a body placed at a pole of the earth is nearer to the centre of gravity than a body placed at the equator; and though this cause alone would not suffice to render the action of gravity greater on the body at the pole, since at the bottom of a mine gravity may be and usually is less than at the mouth (see EARTH), yet under the actual circumstances a body at the pole is on the whole brought under the more effective action of gravity. A complete mathematical comparison of the attractions under the two conditions shows that gravity at the equator, so far as the cause we are now considering is concerned, is less than gravity at the poles by about  $\frac{1}{235}$ . Combining the two effects, we obtain for the total decrease of gravity at the equator:  $\frac{1}{289} + \frac{1}{235} = \frac{1}{135}$ . In other words, if gravity at the poles be represented by 195, gravity at the equator will be represented by 194. Minor causes exist, which however need not here be taken into consideration. We may simply mention that they arise from the non-homogeneity of the earth's substance (near the place of observation), as the existence of cavities, of great masses of unusual density, and so on. The following table shows the results obtained by Capt. Kater in different parts of the British isles:

PLACE OF OBSERVATION.	Latitude.	Longitude.	Vibrations in a mean solar day.	Length of the pendulum vibrating seconds.
Unst .....	60° 45'	28° 01''	86,096·90	39·17146
Portsoy .....	57 40	58·65	86,086·05	39·16159
Leith Fort .....	55 58	40·80	86,079·40	39·15554
Clifton .....	53 27	43·12	86,068·90	39·14600
Arbury Hill ...	52 12	55·32	86,065·05	39·14250
London .....	51 31	8·40	86,061·52	39·13929
Shanklin Farm.	50 37	23·94	86,058·07	39·13614

Deducing from these values the velocity acquired by a body in falling, Capt. Kater found that a body falling at Leith Fort would acquire in one second a velocity of 32·207 feet per second; and that the variation in this velocity for one degree of difference of latitude is at Leith only ·0000332 of its own amount. The following table gives the length of the seconds pendulum at different places, and the value of the accelerating force of gravity according to Sir George Airy:

OBSERVER.	Place.	Latitude.	Length of pendulum vibrating seconds, in inches.	Velocity in feet acquired in one second by a body falling from rest.
Sabine	Spitzbergen	N. 79° 50'	39·21469	82·2528
Sabine	Hammerfest	70 40	39·19475	82·2363
Svanberg	Stockholm	59 21	39·16541	82·2122
Bessel	Königsberg	54 42	39·15072	82·2002
Sabine	Greenwich	51 29	39·13983	82·1912
Borda, Biot, and Sabine	Paris	45 50	39·12851	82·1819
Biot	Bordeaux	44 50	39·11296	82·1691
Sabine	New York	40 43	39·10120	82·1594
Freycinet	Sandwich Islands	20 52	39·04690	82·1143
Sabine	Trinidad	10 39	39·01888	82·0918
Freycinet	Rawak	S. 0 2	39·01493	82·0850
Sabine and Duperrey	Ascension	7 55	39·02363	82·0956
Freycinet and Duperrey	Mauritius	20 10	39·04684	82·1151
Brisbane and Rumker	Paramatta	33 49	39·07452	82·1375
Freycinet and Duperrey	Falkland Islands	51 35	39·13761	82·1895

From these values the following very simple and convenient formula has been deduced: If  $L$  denote the length of a seconds pendulum at any latitude  $\lambda$ , and 39·017 inches be the length of a seconds pendulum at the equator, then  $L = 39·017 + 0·200 \sin^2 \lambda$ .

**GRAVITY, Specific**, the ratio of the weight of one body to that of an equal volume of another, adopted as a standard of reference. For solids and liquids the standard is pure water, at a temperature of 60° F., the barometer being at 30 inches. Air is the standard for æriform bodies. A cubic foot of water weighing 1,000 oz., if the same bulk of another substance, as for instance cast iron, is found to weigh 7,200 oz., its proportional weight or specific gravity is 7·2. It is convenient to know the figures representing this proportion for every substance in common use, that the weight of any given bulk may be readily determined; and for all substances the specific gravity is used among other tests for the purpose of distinguishing bodies from each other, the same substance being found, under the same circumstances, to retain its peculiar proportional weight or density. Hence tables of specific gravity are prepared for reference, and in every scientific description of substances the specific gravity is mentioned. In practical use, the weight of a cubic foot is obtained from the figures representing the density by moving the decimal point three figures to the right, which obviously from the example above gives the ounces, and these divided by 16 the pounds avoirdupois, in the cubic foot. Different methods may be employed to ascertain the specific gravity of solids. That by measuring the bulk and weighing is rarely practicable, nor is it desirable. As a body immersed in water must displace its own bulk of the fluid, the specific gravity may be ascertained by introducing a body, after weighing it, into a suitable vessel exactly filled with water, and then weighing the fluid which is expelled. The proportional weight is then at once obtained. Wax will cause its own weight of water to overflow; its specific gravity is then 1. Platinum, according to the condition it is in, will cause only from  $\frac{1}{11}$  to  $\frac{1}{12}$  of its weight of water to escape,

showing its specific gravity to be from 21 to 21·5. But a more exact method than this is commonly employed. The difference of weight of the same substance, weighed in air and when immersed in water, is exactly that of the water it displaces, and may consequently be taken as the weight of its own bulk of water. The specific gravity then is obtained by weighing the body first in air, and then, suspended by a fibre of silk or a hair, in water, and dividing the weight in air by the difference. If the body is lighter than water, it is to be attached to one heavier, to make it sink; then find the loss of the two by immersion, and also the loss of the heavier body; the difference will express the weight of water displaced by the lighter body, whose weight divided by this difference will give its specific gravity. It is hardly necessary to say that the substance examined must be free from mixture of foreign matters, and especially from cavities that may contain air. Minerals, if suspected to contain such, should be coarsely pulverized, and then the second method above may be conveniently applied to determine their density. The specific gravity of fine powders may be determined by one of the methods employed for ascertaining the specific gravity of fluids, viz.: by comparing the weight of a measured quantity with that of the same quantity of water. A glass vessel called a specific gravity bottle is commonly employed, which is furnished with a slender neck, upon which is a mark indicating the height reached by 1,000 grains of water. The substance to be examined is introduced till it reaches the same mark, and, the weight of the empty bottle being known, only one weighing is required to obtain the result.—A common method for finding the specific gravity of fluids is by the instrument called a hydrometer or areometer, of which several kinds are in use, all dependent on the principle that the weights required to immerse a light body, as a bulb of glass, in different fluids, are proportional to the densities of these fluids. Such instruments are used for ascertaining the specific gravity of liquors, as an indication of their strength. (See **HYDROMETER**.) Gaseous bodies are weighed in a thin glass flask or other vessel made for the purpose, and

provided with a stopcock. The vessel is exhausted of air before the introduction of the gas. The experiment requires particular care, as the result will be found to vary under different conditions of pressure, temperature, and the hygrometric state of the atmosphere. The temperature of the air should be 60° and barometric pressure 30 inches. The specific gravities may also be calculated from the atomic weights of the gases: when the atomic volume is equal to that of hydrogen, it is obtained by multiplying the specific gravity of hydrogen by the atomic weight of the gas; when the atomic volume is half that of hydrogen, the specific gravity of the gas is equal to the specific gravity of hydrogen multiplied by twice the atomic weight of the gas; and when the atomic volume is twice that of hydrogen, the specific gravity of the gas is equal to the specific gravity of hydrogen multiplied by half the atomic weight of the gas.—The proportions of two ingredients in a compound, as in an alloy of gold and silver, may be found by multiplying the specific gravity of each ingredient by the difference between it and the specific gravity of the compound. As the sum of the products is to the respective products, so is the specific gravity of the body to the proportions of the ingredients; then as the specific gravity of the compound is to the weight of the compound, so are each of the proportions to the weight of its material.—The following table presents the specific gravities of substances most likely to be referred to, collected from various sources. The weight of a cubic foot in ounces avoirdupois is seen by moving the decimal point three figures to the right.

TABLE OF SPECIFIC GRAVITIES.

Acid, acetic.....	1.062	Cadmium.....	8.600
arsenic.....	3.391	Caoutchouc.....	0.933
boracic, crystallized.....	1.479	Chalk.....	2.754
boracic, fused.....	1.503	Cinnabar.....	8.998
citric.....	1.034	Clay.....	1.930
hydrochloric.....	1.200	Coal, bituminous.....	1.020 to 1.350
nitric.....	1.271 to 1.583	Cobalt, cast.....	7.812
aqua regia.....	1.234	Copal.....	1.045
phosphoric, liquid.....	1.553	Copper, native.....	8.940
phosphoric, solid.....	2.800	cast.....	8.783
sulphuric.....	1.841	wire.....	8.973
Alabaster.....	1.874	coin.....	8.915
Alcohol, absolute.....	0.792	Coral.....	2.540 to 2.850
of commerce.....	0.835	Diamond.....	3.521 to 3.550
Ale or beer.....	1.035	Dolomite.....	2.540 to 2.830
Alum.....	1.724	Earth, mean of the.....	5.210
Aluminum.....	2.560 to 2.670	globe.....	5.210
Amber.....	1.064 to 1.100	Emerald.....	2.673 to 2.775
Ambergris.....	0.780 to 0.926	Ether, sulphuric.....	0.632 to 0.775
Amethyst, common.....	2.750	Fat of beef.....	0.923
oriental, or violet.....	3.809 to 4.160	Feldspar.....	2.400 to 2.620
sapphire.....	3.809 to 4.160	Freestone.....	2.143
Ammonia.....	0.875	Garnet.....	3.150 to 4.300
Anthraxite.....	1.360 to 1.850	Glass, bottle.....	2.733
Antimony.....	6.702	crown.....	2.520
Asphaltum.....	0.905 to 1.650	green.....	2.642
Barytes.....	4.000	flint.....	2.760 to 3.329
sulphate of (heavy spar).....	4.800 to 4.720	plate.....	2.760
Basalt.....	2.864	plate of St. Gobain.....	2.488
Beeswax.....	0.956 to 0.964	Gold, native.....	19.500 to 19.500
Bismuth.....	9.822	pure, cast.....	19.258
Brandy.....	0.887	hammered.....	19.362
Brass.....	7.824 to 8.396	coin.....	17.647
wire.....	8.544	22 carats fine.....	17.486
Brick.....	1.900 to 2.000	20 carats fine.....	15.709
Bronze, gun metal.....	8.700	Granite, Quincy.....	2.652
Butter.....	0.942	Staten island.....	2.780
		Graphite.....	1.987 to 2.400

Grindstone.....	2.148	Peruvian bark.....	0.784
Gunpowder, loose.....	0.836	Pewter.....	7.471
close shaken.....	0.937 to 1.000	Phosphorus.....	1.770
solid.....	1.550 to 1.800	Platinum, native.....	17.000 to 18.000
Gum arabic.....	1.452	refined.....	19.500
Gypsum, compact.....	1.872 to 2.288	hammered.....	20.336
Heliotrope or blood-stone.....	2.630 to 2.700	wire.....	21.041
Hematite iron ore.....	4.500 to 5.900	laminated.....	22.069
Honey.....	1.456	Porcelain, China.....	2.385
Hyacinth.....	4.000 to 4.750	Sèvres.....	2.145
Ice.....	0.980	Porphyry.....	2.458 to 2.972
Iodine.....	4.943	Potassium.....	0.865
Iridium, hammered.....	23.000	Proof spirit.....	0.923
Iron, malleable.....	7.445 to 7.817	Quartz.....	2.500 to 2.800
cast.....	7.207	Rhodium.....	11.000
cast, magnetic.....	4.900 to 5.200	Rosin.....	1.100
Ivory.....	1.822 to 1.917	Ruby.....	4.283
Lard.....	0.947	Salt, common.....	2.130
Lead, cast.....	11.350 to 11.445	Sand.....	1.500 to 1.800
white.....	7.235	Sapphire, oriental.....	8.994
ore, galena.....	7.250 to 7.780	Serpentine.....	2.507 to 2.591

**GRAY**, a town of France, in the department of Haute-Saône, on the left bank of the river Saône, 30 m. S. W. of Vesoul; pop. in 1866, 6,764. It is on a hill, in the form of an amphitheatre, and the streets are narrow, but the town is pretty well built. The river is spanned by a suspension bridge and one of stone. There are a college, a public library, and a theatre. The chief manufactures are hair cloth, woolen goods, leather, and starch. In the environs are several iron works. Gray is a very ancient town, and was the last place in Franche-Comté which submitted to Louis XIV. in 1668.

**GRAY, Asa**, an American botanist, born in Paris, Oneida co., N. Y., Nov. 18, 1810. He graduated at the Fairfield medical college in 1831, but abandoned the practice of medicine, and applied himself to the study of botany. In 1834 he was appointed botanist to the United States exploring expedition; but as some time elapsed before it was ready to sail, he resigned that situation. In 1842 he was elected Fisher professor of natural history in Harvard college. In his numerous writings he has shown equal ability in communicating elementary knowledge and in elucidating recondite theory. His elementary works, "Elements of Botany," pub-

lished in 1836, and especially his later series, "How Plants Grow," "How Plants Behave," "Lessons in Botany," and "Structural and Systematic Botany" (1858), are unsurpassed in the language for precision, simplicity, perspicuity, and comprehensiveness. His labors are recorded in numerous papers contributed to the principal scientific journals and academical memoirs of the day, and in several special works. He came forward at a time when the old artificial systems of botany were giving way before the natural system. Dr. Gray, with Dr. John Torrey, was among the first who arranged the heterogeneous assemblage of species upon the natural basis of affinity. While actively engaged in describing the new forms which were pouring in upon them from numerous explorations in our hitherto almost unknown territory, they were elaborating the accumulated knowledge of their predecessors which remained in a crude form. In 1838 Dr. Gray commenced, in conjunction with Dr. Torrey, the publication of a "Flora of North America," intended to give a thorough and comprehensive history of the botany of the country upon the basis of the then little known natural system. This was continued as far as the end of the order *compositæ*; but as the explorations of several collectors were accumulating masses of new material from our western borders, the "Flora" was suspended until this wealth of matter could be aggregated under one head. The government expeditions to the Pacific coast also returned laden with botanical treasures, which were described by Dr. Gray and Dr. Torrey in the government reports. In 1848 Dr. Gray began his "Genera of the Plants of the United States, illustrated by Isaac Sprague," and in the same year the "Manual of the Botany of the Northern United States," several editions of which, enlarged and amended, have since appeared. In 1854 appeared the first volume of the "Botany of the United States Pacific Exploring Expedition under Capt. Wilkes," a work in which the author has shown himself able to treat of the botany of remote regions with the same critical power that he has applied to the North American flora. In 1861 he published "A Free Examination of Darwin's Treatise on the Origin of Species, and of its American Reviewers." He is an associate editor of the "American Journal of Science and Arts." In 1873 he retired from active service in teaching, to devote himself to the charge of the herbarium of Harvard college, and to scientific work. In 1874 he was appointed a regent of the Smithsonian institution in place of Prof. Agassiz.

**GRAY, David**, a Scottish poet, born at Duntiblae, near Glasgow, Jan. 29, 1838, died at Merkland, Dec. 3, 1861. His father was a handloom weaver with a large family. David, the eldest, was intended for the ministry. When he was still very young the family removed to Merkland, on the other side of the Luggie, with which stream much of his poetry is as-

sociated. He finished his education with a partial course at Glasgow university, becoming proficient in Greek, Latin, and French. After spending some time there as a private tutor, he wrote to Mr. Milnes (now Lord Houghton), enclosing manuscript poems and asking for advice. Milnes recognized his genius, but discouraged his plan of going to London as a literary adventurer. Nevertheless he went, arriving there early in May, 1860, with but a sovereign in his pocket. He spent the first night in Hyde Park, contracting the pulmonary disease of which he died. Meanwhile he had sent his poem "The Luggie" in manuscript to several literary men of celebrity, but none of them found time to read it. He called on Milnes, who befriended him and sent the poem to Thackeray, for the "Cornhill Magazine;" but Thackeray rejected it. Gray became seriously ill, and Milnes sent him home to Scotland. At last, through the agency of Sydney Dobell, a publisher was found for his poems, and a specimen page of proof reached the author the day before he died. "The Luggie and other Poems" appeared in London in 1862, and in Boston in 1864 (enlarged ed., 1874).

**GRAY, Elisha.** See supplement.

**GRAY, Henry Peters**, an American painter, born in New York, June 23, 1819, died there, Nov. 12, 1877. He entered the studio of Daniel Huntington in 1838, and in 1839 went to Europe, where he painted his pictures of "Thou art Gone," the "Roman Girl," the "Billet Doux," &c. Returning to New York in 1843, he executed a number of small pictures of genre and history; and after another absence abroad in 1845-'6, during which he produced his "Teaching a Child to Pray," "Proserpine and Bacchus," "Cupid begging his Arrows," &c., he settled in New York. Among the most important of his works are the "Wages of War," the "Apple of Discord," "Hagar and the Angel," "Portia and Bassanio," "Charity," "Genevieve," "Cleopatra," "St. Christopher," "I Fiore di Fiesole," and the "Origin of the American Flag." He also painted several hundred portraits. From 1869 to 1871 he was president of the national academy of design. In 1871-'4 he again resided in Europe.

**GRAY. I. John Edward**, an English naturalist, born at Walsall in 1800, died March 7, 1875. For nearly 50 years he was connected with the British museum, and became superintendent of its natural history department. In addition to his labors in arranging the collections of the museum, he was a voluminous contributor to natural history, particularly in the department of zoölogy; and profiting by the advantages which his position has afforded him, he has probably described and classified a larger number of animal forms than any other naturalist. The most valuable of his numerous works are the catalogues of the museum, including those on mollusca, mammalia, and reptiles, in which, besides the lists of animals, he gives much information on the habits, character, and

uses of the different species. His writings are comprised under the following heads: the general subject of natural history, the mammalia, birds, reptiles, fishes, articulate animals, the mollusca, and the radiata. His papers on the mammalia and the mollusca in 1852 amounted to considerably over 100 in each department, those on the latter subject being particularly valuable on account of their extensive and exact information. The most important of them is the "Systematic Arrangement of Molluscous Animals, with Characters of Families." In his conchological studies he received much assistance from his wife, an accomplished naturalist, and the author of "Figures of Molluscous Animals for the Use of Students," descriptions of which were furnished by Dr. Gray. A larger share of his attention was however devoted to herpetology than to any other branch of natural science, and more than 70 papers describing the structure and habits of species from many parts of the world are included among his writings. Dr. Gray was prominent in the work of reforming prison discipline and in sanitary measures, founded the Greenwich society of useful knowledge, and claimed to have originated the plan of cheap postage prepaid by stamps. **II. George Robert**, an English naturalist, brother of the preceding, born at Little Chelsea, July 8, 1808. He early began the study of zoölogy at the British museum, was employed in the zoölogical department from 1831, and in 1869 became assistant keeper of the zoölogical collections. He is the author of several works and papers on entomology and ornithology, and in 1832 contributed the entomological portion to the English edition of Cuvier's "Animal Kingdom." He published a "List of the Genera of Birds," reëdited in 1841 and in 1855. His large work, "Genera of Birds" (3 vols., 1837-'49), is universally valued by naturalists. In 1870 he published his "Hand List of the Genera and Species of Birds," embracing 2,915 genera and subgenera, and 11,162 species.

**GRAY, Thomas**, an English poet, born in Cornhill, London, Dec. 26, 1716, died July 30, 1771. He was educated at Eton and Cambridge, where his expenses were borne by his mother, his father refusing to maintain him. At Eton Gray formed an intimacy with Richard West, a son of the lord chancellor of Ireland, and also with Horace Walpole, with whom in 1739-'41 he travelled in France and Italy. He spent 11 months at Florence, and there began his Latin poem *De Principiis Cogitandi*. He returned in 1741, and became bachelor of the civil law at Cambridge, though he never offered to practise, but continued to live at his university. He corresponded frequently with West, and communicated to him a portion of a tragedy called "Agrippina," in which Nero and his mother and Seneca were to be prominent characters, but which West induced him to abandon. He was easily affected by discouraging criticism, and had nearly laid aside his

"Progress of Poesy" because Mason said he did not think it would take with the public. Having become estranged from Walpole, and West having died in 1742, Gray was much depressed. At this time he wrote his "Ode to Adversity" and the ode "On a Distant Prospect of Eton College." About the same time he was engaged on his Latin poem *De Principiis*, in which he designed to teach Locke's metaphysics in hexameters. From 1742 he remained at Cambridge, always dissatisfied with the place, and never professing contentment. In 1748 he began a poem, which he never completed, "On Government and Education." It has some fine lines, in spite of the unpoetical subject. Gray, although of refined tastes and manners, shrank from society, living chiefly among scholars. He encouraged Mason, then a young poet, revised his verses, and helped him to an election as fellow of Pembroke hall. Mason became his constant associate, and was afterward his biographer. In 1749 Gray finished the "Elegy written in a Country Churchyard," said to have been begun seven years before, in the churchyard of Stoke-Pogis, Buckinghamshire, in which town his mother was living. It originally appeared in 1752, and achieved an immediate popularity, four editions being called for within a year. Several of his pieces were printed in 1753 with designs by Mr. Bentley, and, being too few to make a book of the usual size, were printed only on one side of the leaf. The poems and the plates together sold well. In 1756 he removed to Pembroke hall. His odes, "The Progress of Poesy" and "The Bard," appeared in 1757, and were received with much ridicule. Few professed to understand them, but the public finally learned to admire. His poems were parodied in two odes which not long after appeared on "Obscurity" and "Oblivion." Between the years 1759 and 1762 he occupied lodgings in Southampton row, near the British museum, then just opened, and made extracts from the Harleian and other collections which filled a considerable folio volume. On the death of Cibber the laureateship was offered to him, which he declined. He was appointed in 1768 professor of modern history at Cambridge. His health now rapidly declined. In the autumn of 1770 he was able to travel in Wales; he saw Westmoreland and Cumberland, and wrote in correspondence a delightful narrative of his travels. He died of gout in the stomach, and was buried at Stoke-Pogis. Gray was small, delicate, of handsome features, and studiously refined. His manners were nice to effeminacy, his dress carefully adjusted to the fashions of the day. He speaks of himself as a person of great pride and reserve; but he was capable of strong and tender emotion. He could often be satirical, and among his intimate friends his conversation was singularly entertaining and instructive, but he spoke little in company. To his great attainments all his friends bear testimony, but he left no public

proof of them. He was a botanist, a zoölogist, an architect, and an antiquary. He had read all the Greek classics, and planned an edition of Strabo. He was familiar with history, was learned in art, had studied the schools of philosophy, and wrote better Latin verse than any of his contemporaries. His "Elegy" is the culmination of his genius, almost every line having fixed itself upon the popular mind. Among the best of the numerous editions of Gray's poems are those by W. Mason, with his letters and a memoir (4 vols. 8vo, York, 1778); and by the Rev. John Mitford, with notes and a memoir (London, 1814), several times republished. An edition of his complete works, with Mason's memoir, was issued by T. J. Mathias (2 vols. 4to, London, 1814). Mr. Mitford also published in 1853 Gray's correspondence with Mason, showing that the poet's letters were mutilated by Mason in his edition.

**GRAYDON, Alexander**, an American author, born in Bristol, Pa., April 10, 1752, died in Philadelphia, May 2, 1818. He was educated in Philadelphia, and in 1775 joined the colonial forces as captain. After carrying a supply of money to the troops under the command of Gen. Schuyler at Lake George, he joined the army at New York, and was taken prisoner in the action on Harlem heights. He was confined in New York and at Flatbush, was afterward liberated on parole, and exchanged in 1778. He resided in Harrisburg from 1785 to 1799, when he removed to a farm near that city, from which he returned to Philadelphia in 1816. He published in 1811 his "Memoirs of a Life, chiefly passed in Pennsylvania, within the last Sixty Years," illustrative of revolutionary manners and history. It was republished in Edinburgh (1822) and in Philadelphia (1846).

**GRAYLING**, a soft-rayed fish, of the salmon family, and genus *thymallus* (Cuv.), found in the rivers of northern Europe, Asia, and America. The English grayling has the head and body elongated, the former pointed and flattened on the top; two dorsals, the first much longer than it is high and with numerous rays, the second small, adipose, and rayless; the mouth small; the teeth numerous, conical, small, in a single series on the jaws and anterior part of the vomer, none on the tongue; the scales rather large, and the lateral line not very conspicuous; the air bladder is capacious, and communicates with the gullet by a very small tube; the caudal is forked; branchiostegal rays seven or eight. It is very handsome and lively, though less active than the trout; the general color is light yellowish brown, with reflections of golden, copper, green, and blue, and some dark spots; the head brown, and the fins darker than the body; the dorsal fin is varied with square dusky spots; the colors grow darker by age, and in dark waters; the iris is golden yellow, and the pupil blue. This is probably the *T. vulgaris* (Nilss.), found in a few of the rivers of England, in restricted localities, in Sweden, Norway, and Lapland,

but probably not in Ireland or Scotland. It prefers rivers with rocky and gravelly bottom, with alternate stream and pool; it swims deeper than the trout, and feeds on flies and aquatic larvæ, especially on those which construct cases (like the May flies), and on small shells and crustaceans. It is excellent for the table, is in the finest condition in October and November, and should be dressed soon after being taken; it rises to the fly, but less readily than the trout. From the size of its dorsal it cannot stem rapid currents nor leap falls. The generic name was given from an alleged resemblance of the odor of its flesh to that of thyme; from its color and odor St. Ambrose is said to have called it the "flower of fishes." Unlike other *salmonidæ*, it spawns in April or May; the average length is 10 or 12 in., with a weight of about 1½ lb., but they have been taken weighing 4½ lbs. For a full and interesting account of the habits and history of this fish, the reader is referred to the seventh "Conversation" in "Salmonia," by Sir Humphry Davy. Other species are the *T. vezzilifer* (Ag.), from the rivers of France and the Swiss lakes and streams; and the naked-throated grayling (*T. gymnothorax*, Val.), in

Back's Grayling (*Thymallus signifer*).

which the parts beneath the throat are destitute of scales, found in Prussia and Russia. The grayling is called *ombre* in French and *Aesche* in German, probably from its prevailing ashy gray color in the water. In America, this fish has been found in the cold clear waters of Great Bear and Winter lakes, and in streams emptying into Mackenzie river. Back's grayling (*T. signifer*, Rich.) has not been discovered south of lat. 62° N.; this is a large species, about 17 in. long, and highly esteemed by the Esquimaux and the *coyageurs*.

**GRAYSON. I.** A S. W. county of Virginia, bounded S. by North Carolina and N. W. by the Iron mountain; area, 400 sq. m.; pop. in 1870, 9,587, of whom 754 were colored. It is intersected by Kanawha or New river. The county is well adapted for grazing. Iron ore is abundant. The chief productions in 1870 were 30,060 bushels of wheat, 42,704 of rye, 109,938 of Indian corn, 63,695 of oats, 12,313 of potatoes, 91,543 lbs. of butter, 25,326 of wool, and 4,016 tons of hay. There were 2,056 horses, 2,947 milch cows, 4,057 other cattle, 11,811 sheep, 7,778 swine, and 4 flour mills. Capital, Independence. **II.** A N. county of Texas, separated by Red river from the In-

dian territory; area, 950 sq. m.; pop. in 1870, 14,387, of whom 2,145 were colored. The surface is undulating and partly covered with forests of oak, ash, and elm. The soil is a dark fertile loam, suitable for various kinds of fruit, grain, cotton, and pasturage. The chief productions in 1870 were 39,768 bushels of wheat, 577,540 of Indian corn, 113,241 of oats, 39,411 of sweet potatoes, 111,840 lbs. of butter, and 2,885 bales of cotton. There were 7,324 horses, 4,840 milch cows, 26,167 other cattle, 5,911 sheep, 18,535 swine, 4 saw mills, and 4 wool-carding establishments. Capital, Sherman. **III.** A central county of Kentucky, bounded N. by Rough creek and drained by several affluents of Green river; area, about 700 sq. m.; pop. in 1870, 11,580, of whom 407 were colored. It is traversed by the Elizabethtown and Paducah railroad. The surface is level or undulating and the soil moderately fertile. Anthracite and carboniferous limestone are found in abundance, and there are several white sulphur springs. The chief productions in 1870 were 25,448 bushels of wheat, 377,005 of Indian corn, 80,953 of oats, 20,722 of potatoes, 149,001 lbs. of butter, 859,760 of tobacco, and 1,398 tons of hay. There were 3,172 horses, 2,816 milch cows, 4,158 other cattle, 14,543 sheep, and 17,934 swine; 3 flour and 4 saw mills, and 3 wool-carding and cloth-dressing establishments. Capital, Litchfield.

**GRAZIANI, Francesco**, an Italian vocalist, born at Fermo, April 26, 1829. He became famous in Paris in 1851 as Aston in *Lucia di Lammermoor*, and sustained his reputation as one of the best baritones of the day by his subsequent performances in Florence, New York, London, and St. Petersburg.—His brother **LUDOVICO**, born in August, 1823, excels as a tenor; the part of Germion in *La traviata* was written for him.

**GREAT BARRINGTON**, a town of Berkshire co., Massachusetts, on the Housatonic river and railroad, 40 m. W. of Springfield; pop. in 1870, 4,320. It is pleasantly situated, watered by a number of good mill streams, and surrounded by beautiful hills. It contains beds of iron ore and quarries of fine variegated marble. The manufactures embrace cotton goods, paper, woollens, pig iron, bricks, and saw-mill products. It has a national bank, a savings bank, a weekly newspaper, 18 public schools, including a high school, and 7 churches. It comprises three villages, viz.: Great Barrington, Housatonic, and Van Deusenville. Great Barrington was the county seat till 1787.

**GREAT BASIN**, or **Fremont's Basin**, the region lying between the Wahsatch mountains on the east and the Sierra Nevada on the west, embracing Nevada, the W. portion of Utah, and the S. E. part of California. In shape it resembles an ancient shield, the broad end toward the north, and the S. extremity rounded to a point. Its waters have no outlet to the ocean, and it evidently formed at a remote period an inland sea. The greatest depressions are near the borders, especially along the E. and W.

sides, while the central portion reaches a much greater elevation, and is broken into a series of detached ridges. Along the line of the Central Pacific railroad the elevations are as follows: at Brigham, on the border of Great Salt lake, 4,220 ft. above the level of the sea; at Pequop, a short distance W. of the Nevada boundary, 6,184 ft.; and at Desert, in the W. part of Nevada, 4,017 ft. The height at the points of greatest depression in the S. E. and S. W. parts has not been accurately determined, but in the neighborhood of Sevier lake it is not more than 4,500 ft. above the sea. The highest ranges in the basin probably attain an elevation of from 7,500 to 8,000 ft. The Wahsatch range, which, running almost directly N. and S. near the 112th meridian, forms the E. rim, rises abruptly from the narrow plains, seldom sending out foot hills or slopes. The mountain ridges in the interior, separated by valleys of various width, run parallel to each other in a N. and S. direction, determining the course of the minor streams, though the few principal rivers break through them. The elevation which forms the N. rim, separating the basin from the valley of the Columbia, also consists of parallel ridges running N. and S. The principal body of water is Great Salt lake in the N. E. part, the region draining into it being known as the Great Salt Lake basin. Other lakes are Utah and Sevier, in Utah; Walker's lake, Carson lake, Pyramid lake, and Mud lake, in Nevada; and Mono and Owen's lakes, in California. Bear river empties into Great Salt lake; the Provo or Timpanogas into Utah lake; while the Jordan discharges the waters of Utah lake into Great Salt lake. Sevier, Walker's, Carson, and Owen's lakes receive rivers of the same names; the Truckee empties into Pyramid lake. Humboldt river rises in the N. E. part of Nevada, and after a course a little S. of W. of about 300 m. disappears in the "Humboldt sink." Reese river flows N. toward the Humboldt, but generally sinks before reaching it. The greater portion of the basin is an arid and sterile waste, covered with alkaline deposits, and producing only a growth of sage brush. Considerable tracts, however, may be rendered productive by irrigation, and larger portions are adapted to grazing. Except upon the mountains in the N. part forests scarcely exist. The climate is dry, rain rarely falling from April to October. The basin is rich in the precious metals, particularly silver.

**GREAT BEAR LAKE.** See BEAR LAKE.

**GREAT BRITAIN**, in a geographical sense, the largest and most important island of Europe, and in a political sense, as popularly used, the British empire, or the United Kingdom of Great Britain and Ireland. Britain (Britannia) was the ancient name of the island, by which it was known to the Romans. The western peninsular projection of France, called by the Romans *Armorica*, was occupied by the same race that constituted the aboriginal population of Britain. As early as the 6th century of our

era, the French applied the term *Bretagne* (Britain) to *Armorica*, and to distinguish the continental from the insular Britain, called the former "Little Britain" and the latter "Great Britain." The term Great Britain was little used by the islanders themselves until the accession of James I. to the crown of England in 1603 united the whole of the island under one sovereign. By the legislative union between England and Scotland in 1707 Great Britain became the legal name of the kingdom. The island comprises England, Wales, and Scotland. Scotland is frequently termed North Britain. The official style of the empire is "The United Kingdom of Great Britain and Ireland," but in current language the term Great Britain includes politically the British and Irish kingdoms, and is the common designation of the whole imperial power. (See *BRITISH EMPIRE*, *ENGLAND*, *SCOTLAND*, and *WALES*.)

**GREAT FALLS.** See *SOMERSWORTH*.

**GREAT GRIMSBY**, a parliamentary and municipal borough and seaport of Lincolnshire, England, on the right bank of the Humber, 30 m. N. E. of Lincoln; pop. in 1871, 20,238. The town consists of two portions: the older is at the head of the harbor, and the newer, called the Marsh, extends along the east side of the harbor. It has free grammar schools, a national school, a mechanics' institute, and a new town hall. There is a large trade in fish, timber, coal, and salt.

**GREAT KANAWHA RIVER**, a large stream of North Carolina and the Virginias, called in the upper part of its course New river. It rises in the N. W. part of the former state, between the Blue Ridge and Iron mountain, and flows N. E. to the N. part of Grayson co., Va., where it passes through a defile in the Iron mountain, and, bending toward the N. W., breaks through Walker's, Peter's, and Greenbrier ridges of the Alleghanies. After receiving Gauley river in Fayette co., W. Va., it takes the name of Great Kanawha, passes through the coal and salt region, and joins the Ohio at Point Pleasant, Mason co., W. Va. Its length is about 400 m.; its width 66 m. above its mouth is 450 ft., and at the junction of Gauley river, 100 m. above its mouth, 1,500 ft. It is navigable at all seasons to a point about 2 m. below the Gauley, where the river has a picturesque perpendicular fall of 50 ft. Its principal affluents are the Greenbrier, Gauley, and Elk on the north, and Coal river on the south. The principal towns on its banks are Pearisburg, Va., and Fayetteville, Charleston, and Point Pleasant, W. Va.

**GREAT MARLOW**, a town of Buckinghamshire, England, on the Thames, 11 m. N. E. of Reading; pop. in 1871, 6,619. It has a fine church, manufactories of paper and lace, and a considerable trade in lumber, coal, and corn.

**GREATOREX, Eliza**, an American artist, born at Manor Hamilton, Connaught, Ireland, Dec. 25, 1820. She is the daughter of the Rev. J. C. Pratt, a Wesleyan minister. When 19 years

old she came to the United States, and married Henry W. Greatorex, the son of the organist of Westminster abbey. From 1854 to 1856 she studied landscape painting with W. W. Witherspoon of New York, and then visited England and Ireland, making drawings of lake scenery. In 1862 she studied under Edouard Lambinet in Paris, and afterward sketched along the Rhine. She went again to Europe in 1866, and made pen-and-ink drawings in England, Holland, Germany, Italy, and Paris. In 1868-'9 she made pen-and-ink drawings of the old buildings in and around New York. In 1870 she returned to Europe and studied landscape and architectural drawing in Munich, where she published in 1872 "The Homes of Oberammergau" (New York, 1873), a series of 20 etchings from pen-and-ink sketches, with notes from her diary. In 1873 she published "Summer Etchings in Colorado," with 21 illustrations, and an album of "Etchings in Nuremberg." Her best known oil paintings are a "View on the Housatonic" (1863), "The Forge" (1864), and "Somerindyke House" (1869).

**GREATRAKES, Valentine**, an Irish quack, born at Affane, county Waterford, Feb. 14, 1628, died in Dublin, probably about 1700. He was educated at Trinity college, Dublin, and on the outbreak of the rebellion went to England, where he devoted some time to the study of the classics and divinity. He served in the parliamentary army from 1649 to 1656, when he returned to Ireland and was made a justice of the peace in county Cork, and held other offices which were taken from him at the restoration. Soon afterward he claimed the power to cure the king's evil and all other diseases by the touch; and in 1665 he went to London, where the king invited him to Whitehall, and where he is alleged to have performed many cures, which were attested by Robert Boyle, Sir John Godolphin, and many other eminent persons. Dr. Henry Stubbe published a pamphlet in praise of Greatrakes's skill, under the title "The Miraculist Conformist" (Oxford, 1666). Greatrakes having failed in one instance to effect a cure, David Lloyd published a pamphlet entitled "Wonders no Miracles" (London, 1666), in which he denounced him as a cheat. To this Greatrakes replied in a letter addressed to Boyle, entitled "Account of Val. Greatrakes and divers of his strange Cures." In 1667 he returned to Ireland.

**GREAT SALT LAKE**, an extensive sheet of water in Utah, lying in the Great Basin, between lat. 40° 40' and 41° 45' N., and lon. 111° 50' and 113° 10' W. Its outline is somewhat irregular. There are several islands, of which the principal are Church or Antelope island in the southeast, and Stansbury island in the southwest. The lake is 75 m. long from N. W. to S. E. and about 30 m. broad. Its surface is 4,200 ft. above the level of the sea. It has no outlet. The water is shallow, the depth in many extensive parts being not more than 2 or 3 ft. Utah lake, a body of fresh water

35 m. long and 100 ft. above the level of Great Salt lake, is 26 m. S. E. of the latter, and flows into it through a river called the Jordan. Utah lake abounds with fish. Bear river flows into the Great Salt lake from the north, and several smaller rivers from the east. The floods of spring spread the lake over large tracts, from which it recedes as summer advances. It was evidently once vastly more extensive than at present. The country around it is mostly desolate and barren, though there are portions which irrigation would render very fertile. The water is transparent, but excessively salt; it contains about 22 per cent. of chloride of sodium (common salt), slightly mixed with other salts, forming one of the purest and most concentrated brines in the world. Its specific gravity is 1.17. There are no fish in the lake, but several species of insects and a species of crustacean (*artemia fertilis*) have been found (see "United States Geological Survey of the Territories" for 1872, pp. 744-'5); and immense flocks of gulls, wild ducks, geese, and swans frequent its shores and islands. The water is so buoyant that a man may float in it at full length upon his back, having his head and neck, his legs to the knee, and both arms to the elbow, entirely out of water. If he assumes a sitting position, with the arms extended, his shoulders will rise above the water. Swimming, however, is difficult from the tendency of the lower extremities to rise above the surface; and the brine is so strong that it cannot be swallowed without danger of strangulation, while a particle of it in the eye causes intense pain. A bath in this water is refreshing and invigorating, though the body requires to be washed afterward in fresh water.—The first mention of the Great Salt lake was by Baron La Hontan in 1689, who gathered from the Indians west of the Mississippi some vague notions of its existence. It was explored and described in 1843 by Fremont, who was the first to navigate its waters. A thorough survey was made in 1849-'50 by Capt. Howard Stansbury of the United States army, whose report of "An Expedition to the Valley of the Great Salt Lake" was printed at Washington by order of congress in 1852. Another edition was published at Philadelphia in 1855.—"The City of the Great Salt Lake," commonly called Salt Lake City, is situated on the Jordan river, which connects Lake Utah with the Great Salt lake, about 7 m. S. of the latter. (See SALT LAKE CITY.)

**GREAT SLAVE LAKE** (Fr. *Lac de l'Esclave*), a large irregular sheet of water in a district of the same name in the northwest territories of Canada, between lat. 60° 40' and 63° N., and lon. 109° 30' and 117° 30' W.; length from E. to W., 300 m.; greatest breadth, 50 m. Its N. shores are steep and rough, and from them it receives the outlets of Aylmer and Artillery lakes. On the south it presents a less rugged bank, and is entered by a river of its own name, flowing N. for about 300 m. from the W. end

of Lake Athabasca. It contains a number of islands, some of which are well wooded. For half the year it is frozen over. Mackenzie river connects it with the Arctic ocean.

**GREAVES, John**, an English mathematician and antiquary, born in Hampshire in 1602, died in London, Oct. 8, 1652. He was educated at Oxford, and in 1630 was chosen geometrical lecturer in Gresham college, London. After visiting Holland, France, and Italy, he embarked in 1637 for Constantinople, whence he went to Egypt to examine the pyramids, of which no satisfactory account had then been given, and in 1640 returned to England, bringing with him several Arabic, Persian, and Greek manuscripts, and a large collection of gems, coins, &c. Soon after his return he was appointed Savilian professor of astronomy at Oxford. In 1648, having been ejected from Oxford for royalism, he settled in London. He published a "Discourse on the Roman Foot and Denarius" (1647), wrote a Persian grammar, and partly compiled a Persian lexicon. A collection of his minor papers was published in two volumes in 1737.

**GREBE**, a lobe-footed bird of the family *colymbidae*, and subfamily *podicipinae*, comprising the genera *podiceps* (Lath.) and *podilymbus* (Lesson). The genus *podiceps* has a long, straight, and slender bill, the culmen slightly curved at the tip, which is sharp and entire, the sides compressed, and the nostrils longitudinal and in a short groove; the wings short and pointed, the first and second quills the longest and slightly emarginated near the tips; tail short, a mere tuft of loose feathers; tarsi shorter than the middle toe, much compressed, covered with scales serrated posteriorly; toes long, lobed on the sides, and united by webs at the base; hind toe short and broadly lobed; nails short, broad, flat, and obtuse. More than 20 species are described, in all parts of the world; they are usually seen in small flocks on the shores of fresh-water lakes and rivers and near the seacoast, and rarely on land, as the posterior position of the legs renders it very difficult for them to walk; they are excellent swimmers and expert divers, flying under water to a considerable depth in pursuit of fish; they are generally short and rapid flyers, but during their migrations the flight is elevated and long sustained; when alarmed, they hide among the reeds, or sink under water, leaving only the bill out, till the danger is over. The food consists of fish and aquatic animals and plants; the nest is made of grasses, lined with down, attached to the reeds or floating; the eggs are three or four in number. The American species vary much in size; one of the largest is the crested grebe (*P. cristatus*, Lath.), 24 in. long, with an extent of wings of 33; the adult male has a blackish brown bill, about 2½ in. long; upper part of head and crest, nape and upper plumage, blackish brown; the ruff, which birds of this genus have in the breeding season, is reddish brown ending in

black; cheeks, throat, band before eye, humeral feathers, and secondaries white; fore part and sides of neck reddish brown; rest of under parts silvery white; primaries dark brown; iris bright carmine; in the females and young the crest is very slight, and the up-

Crested Grebe (*Podiceps cristatus*).

per parts are tinged with gray. It is found along the Atlantic coast from the fur countries, where it breeds, southward, and as far as Texas in the winter, and also on the Pacific shore. All the species have the head rather small, the eyes near the bill, the neck long and slender, and the body flattened; the plumage is thick and soft, and silky on the under surface. The red-necked grebe (*P. griseigena*, Gray), 18 in. long, is found from the fur countries as far south as Pennsylvania in the winter; it is a stouter bird, with shorter neck and smaller crest and ruff, than the preceding species. The largest known species is the western grebe (*P. occidentalis*, Lawrence), 29 in. long, with an extent of wings of 3 ft.; it inhabits the Pacific coast from Washington territory to California. The horned grebe (*P. cornutus*, Lath.) is about 14 in. long; the sides of the head are tufted, and of a yellowish red color; the feathers of the upper parts are margined with gray; throat glossy black; fore neck and upper breast chestnut red; lower parts shining white. It is very generally distributed over North America; it is known to gunners as the "hell diver," from its activity in diving; like that of all the grebes, the flesh has a strong fishy flavor, and is rarely eaten except by the northwest Indians, who also make under garments of the soft plumage of the lower parts.—In the genus *podilymbus* the bill is shorter than the head, strong, with the culmen much arched to the tip, which is hooked over the lower mandible; there are no ornamental ruffs. Only two species are described, one in North and the other in South America, generally distributed over the temperate regions, preferring

fresh water. The pied-bill grebe, or dobchick (*P. podiceps*, Lawr.; *P. carolinensis*, Lath.), is 14 in. long, with a pale blue bill crossed by a black band; the upper plumage very dark brown; chin and throat with a black patch; cheeks, sides of neck, and abdomen grayish white; upper breast and sides rusty brown; the female has not the black patches.

**GREECE**, a country of southeastern Europe, occupying the central and southern portions of the large and irregular peninsula which extends into the Mediterranean between the Ionian and the Aegean seas. By its own inhabitants, both in ancient and modern times, the country has been called Hellas; but the early population of Italy, gaining their first knowledge of the region from the Græci (*Ἕλληνες*), one of its northern tribes, formed from this tribal designation a name for the entire country (*Græcia*). From this have been derived the names given to it in most of the European languages (Fr. *la Grèce*, Ger. *Griechenland*, Ital. *Grecia*, &c.). In treating of the political and physical geography of Greece, we shall devote the first portion of this article to the description of the ancient country, reserving for a subsequent division an account of the modern kingdom.—Many difficulties attend the definition of the northern limits of ancient Greece, the amount of territory included in the possessions of the country varying greatly at different periods. Considering Greece proper as excluding Macedonia, Illyria, and Thrace, but including Thessaly and the greater part of Epirus, it began about lat. 40° N., where a natural boundary was formed by a chain of mountains extending from the Thermaic gulf on the east, and terminating in the Acrocerania promontory, on the Adriatic, on the west. From this boundary the peninsula of Greece extends southward to lat. 36° 23'. Its greatest length, exclusive of the Acrocerania projection, from Mt. Olympus in the northeast to Cape Tænarum at the southern extremity, is about 250 m.; its greatest width, from the W. coast of ancient Acarnania to Marathon, N. E. of Athens, is about 165 m. The area of the ancient country, excluding Epirus, but including the island of Eubœa, was about 21,000 sq. m. The mainland of Greece, deeply indented at several points by gulfs and almost landlocked bays, and crossed by mountain ranges, is naturally divided into three principal regions, northern and central Greece and the Peloponnesus. Northern Greece, extending from the N. boundary to the point where the peninsula is narrowed by the opposite Ambracian and Maliac gulfs, included Epirus and Thessaly, regions nearly equal in size. Central Greece, that part extending from this point to the narrow isthmus of Corinth, comprised the divisions of Acarnania (at the western extremity), Ætolia (the next division toward the east), Ozolian Locris, Phocis, and Boeotia, these three bordering on the gulf of Corinth; Epicnemidian and Opuntian Locris and Doris to

the north of these; Attica, forming the eastern extremity of the whole peninsula; and Megaris, on the narrow land N. E. of the isthmus of Corinth, and between the Corinthian and Saronic gulfs. The Peloponnesus, including all of Greece S. and W. of the isthmus of Corinth, comprised Achaia and Sicyonia, on the Corinthian gulf; Corinthia, on the isthmus and the Corinthian and Saronic gulfs; Argolis, Laconia, Messenia, and Elis, all coast countries; and in the centre, completely surrounded by these, Arcadia. The exact boundaries of all the Greek states were frequently varied by war and political changes, but the divisions named above retained their identity throughout the period of the country's ancient history. The islands which lie in the Ionian and Ægean seas, and in the Mediterranean, within a short distance of the coasts of the peninsula, formed an important part of the ancient Greek possessions. Of these islands, the largest is Eubœa, about 100 m. long and 6 to 30 m. wide, lying E. of central Greece. S. E. of this lie the Cyclades, the large group which surrounded the famous holy island of Delos. E. of the Cyclades, and along the Asiatic coast, extend the Sporades. The islands of Crete and Rhodes lie further S. in the Mediterranean sea. Between Attica and Argolis, in the Saronic gulf, are Salamis and Ægina. Along the W. coast of Greece, in the Ionian sea, extend Coreyra, Paxos, Leucas, Cephallenia, Ithaca, and Zacynthus, which with Cythera, at the S. extremity of Laconia, are now known as the Ionian islands.—The surface of Greece is mountainous through almost its whole extent. The continuous range already mentioned as forming the N. boundary of the ancient country, including Mt. Olympus and the Cambunian and Ceraunian mountains, is crossed at its centre by the great chain of Pindus, which, running nearly N. and S. through the middle of northern Greece, formed a natural boundary between ancient Epirus and Thessaly. Near its S. end it divides into two branches, one stretching S. E. through central Greece, bearing the names of Æta, Parnassus, Helicon, Cithæron, and Hymettus, and finally terminating at the extremity of Attica; the other extending S. W. under the names of Corax and the Ozolian mountains, and terminating near the W. end of the Corinthian gulf. The mountains of the Peloponnesus, also very numerous and closely connected, nevertheless belong to an entirely different system from that of the Pindus; instead of stretching in long ranges through the peninsula, they are clustered in knots and groups around a lofty central mass, which rises in northern Arcadia to the height of nearly 8,000 ft. The principal peaks of the whole country are as follows: in northern Greece, Mts. Olympus (9,754 ft.), Ossa (6,407), and Pelion (5,000); in central Greece, Mts. Parnassus (highest summit, 8,068), Æta (7,071), Helicon (about 5,000), Cithæron (4,620), and Parnes (4,193); in the Peloponnesus, Cyllene (7,788), Erymanthus (7,297), Taygetus (highest

peak, 7,904), Artemisius (5,814), and Lycæus (4,659). The mountain system, the chief ranges of which have been thus described, had a very important effect upon the political as well as the physical divisions of ancient Greece. By dividing with natural walls the habitable and arable plains and less rugged portions of the country one from another, it prescribed the boundaries of states almost as definitely as could have been done by the most exact treaties.—The rivers of Greece are generally unimportant, save on account of their historic associations. Many of the streams are entirely dry during the summer months; none are navigable at any season. In northern Greece the principal rivers are the Achelous, rising in the Pindus in N. E. Epirus, and flowing S. through Epirus and central Greece into the Ionian sea, and the Peneus, also rising in the Pindus, and flowing E. through northern Thessaly into the Thermaic gulf. In central Greece are the Cephissus in Phocis and Bœotia, and the Asopus in Bœotia. In the Peloponnesus are the Alpheus in Arcadia and Elis, and the Eurotas in Laconia. Small lakes are numerous, and there are several of noteworthy size: Nessonis and Bœbeis in Thessaly, Trichonis in Ætolia, Copais in Bœotia, and Stymphalus and several others in Arcadia.—The climate of Greece, which is generally temperate and pleasant, would appear to have been more generally healthy in ancient times than of recent years. Such of the classic authors as allude to it, speak of it as peculiarly bracing and invigorating, and do not notice the malarial tendencies which now render the summer months unhealthy except in the higher regions. The denser population and the universal cultivation of the land in ancient times probably in part prevented this evil. The mineral and vegetable productions of the country will be noticed in treating of the modern kingdom. Of the fauna of the peninsula it is also unnecessary to speak here, as the races of domesticated animals are the same in modern times as among the ancient peoples; while the few kinds of wild animals (wolves, wild boars, and bears) did not differ from those common to the southern parts of Europe. Traditions seem to indicate that lions may have been found in the country at a very early period.—The questions of the origin and race characteristics of the ancient inhabitants of Greece are inextricably connected with the early history of the country; they are treated to some extent in the articles on the different divisions, and will be further noticed in the historical portion of this article. Trustworthy estimates of the numbers of the population, even at the best known periods of Grecian history, are altogether wanting.—The early history of Greece is involved in obscurity, and confused by tradition and fable. Whether the first emigrants from Asia found in Greece aboriginal tribes whom they subdued or with whom they united, or whether they found the land unoccupied, there are no means at present of deciding.

The earliest authentic traditions represent the new comers as arriving among autochthonous populations, and bringing with them religion and the arts from their primeval home. The Greeks were fond of tracing their origin back to a common ancestor, Hellen, the son of Deucalion and Pyrrha, the survivors of the deluge; and the great divisions of the race, the Dorians, Æolians, Ionians, and Achæans, claimed to be descended from Dorus and Æolus, sons of Hellen, and Ion and Achæus, sons of Xuthus, the third son of Hellen. According to the popular belief, Æolus succeeded Hellen as king of Phthia in Thessaly, and his descendants spread over central Greece as far as the isthmus of Corinth, and occupied the W. coast of the Peloponnesus. The Dorians, from which race the Spartans of the historic time were descended, were confined to Doris, between Thessaly and Phocis; the Ionians, the progenitors of the Athenians of the historic period, occupied Attica and the north of the Peloponnesus; the Achæans in the heroic age occupied Mycenæ, Argos, and Sparta, in the Peloponnesus, and the original abode of the Hellenes in Thessaly. The first inhabitants of Greece were called Pelasgians by the Greeks themselves, and were considered by them as a different race from the Hellenes, with a different language. Whether the Pelasgians themselves came in from Asia, at a period beyond the reach of tradition, cannot be satisfactorily determined. The most consistent hypothesis is that which considers the Pelasgic populations as representing the body of the primitive inhabitants of Greece, and as having formed the basis of the subsequent nationalities. We may consider the Hellenic as representing the later and more civilized accessions, which, blending with the Pelasgic, developed that peculiar type of intellectual character which distinguished the Greek from every other ancient race. It was believed that Egyptian and Phœnician immigrants, arriving at a very early period, and bringing with them arts, culture, and religious rites, from countries of a much more ancient civilization, contributed largely to this result. Thus Cecrops, according to the traditions, brought civilization from Sais in Egypt to Athens; and the name of Cecropia, borne by the Athenian Acropolis, commemorated this. Argos was founded by Danaüs, who fled from Egypt with his fifty daughters, to escape the persecutions of the fifty sons of Ægyptus. Pelops led a colony from Asia Minor, and gave the name of Peloponnesus to the S. peninsula. Cadmus came from Phœnicia to Thebes, and introduced the Phœnician art of writing. It is quite possible that all these legends may have their origin in historical facts. It is certain that there was a frequent intercourse by sea in the earlier periods between the Greeks and Phœnicians; and the Greek alphabet, at whatever time it was introduced, is apparently of Phœnician origin. E. Curtius, a high authority, has recently elaborated the theory

of the early Ionians. (See IONIANS.) The heroic age of Greece is the legendary period in which flourished a race of men represented as being descended from the gods, and who are called heroes, a term implying the possession of a nature superior to that of common mortals, as Hercules, Theseus, and Minos. In this period were placed by the poets a series of expeditions and exploits, famous in the literature of Greece, as the voyage of the Argonauts in search of the golden fleece, the war of the seven chiefs against Thebes, the war of the Epigoni, and, last and most famous of all, the siege and capture of Troy, and the return of the heroes, which form the conclusion of the heroic age. Here, too, we may reasonably suppose that historical facts furnished the germ of the legends; but as the whole treatment of them is poetical, it is impossible to separate fact from fiction with any certainty or even probability. The poems of Homer contain all that we know of the manners and society of the heroic age; and the general delineations of heroic society, as given in them, may be received as representing substantially what was believed by the Greeks themselves in the subsequent period. Among the later legends are those of the migrations of the Bœotians from Thessaly into the country called from them Bœotia, said to have taken place 60 years after the fall of Troy; and the conquest of the Peloponnesus by the Dorians, placed 20 years later. They were said to have been led by the descendants of Hercules, who claimed the possession of the country as an ancestral right. This enterprise gave rise to the Dorian states of the Peloponnesus, and is known in history as the return of the Heraclidæ. The establishment of Greek colonies in Asia Minor belongs to the period following the Trojan war. The migrations appear to have continued through several ages, and were, partly at least, owing to movements and disturbances among the populations of Greece. In the course of time Greek colonies were spread over the whole W. coast of Asia Minor, and numerous cities were founded. The N. portion of the coast, with the islands of Tenedos and Lesbos, was occupied by the Æolians; the Ionians took the central part, with the islands of Chios, Samos, and the Cyclades; while the S. W. corner, with the islands of Rhodes and Cos, was settled by the Dorians. The Æolian migration was the earliest, but the Ionian was the most important. There were eleven Æolian cities in historical times. The Ionians formed twelve states united by the worship of Poseidon at the Pan-Ionic festival. The Dorians had six colonies, which formed the confederation of the Doric Hexapolis. We have no trustworthy chronology for whatever of historical events may form the basis of these traditions; but there can be no question of the facts of such migrations having taken place, and we may assume the date of about 1000 B. C. as closing the period within which these

movements occurred.—The authentic history and chronology of Greece commence with the beginning of the Olympiads, 776 B. C. At this period we find Greece divided into a number of small states, under separate governments, united into confederacies for permanent or occasional objects, but with no central government to control the whole. The Grecian world was, however, bound together by language, blood, common religious rites and festivals, social institutions and laws, which distinguished it from the barbarian nations and races about it. The language was divided into dialects, but with sufficient resemblance to each other to be easily understood by all. In the religious systems, particular deities were specially worshipped by particular tribes and at particular places, but the general principles were everywhere the same. Religious rites were periodically celebrated, at festivals in which associations of neighboring states participated, under the general name of amphictyonies, or at the great national games. The amphictyonic council, held alternately at Delphi and at Thermopylæ, was partly political and partly religious. The Olympic, Pythian, Nemean, and Isthmian festivals tended strongly to keep alive the sentiment of Hellenic unity. The establishment of oracles, enjoying authority over the Hellenic world, was another bond of union. Notwithstanding these national ties, the several states of Greece could never be brought into a voluntary political union under a government having the right and power to interfere with the cherished autonomy of each individual state. Excepting in great crises of their history, such as, in the legendary times, the Trojan war, and in historical times the Persian invasion, their patriotism was local, and they never acted for a common object. Indeed, they had no common designation, as Thucydides truly remarks, until gradually the name of the Hellenes supplanted the rest.—In the early historical times the Dorians had become masters of the E. and S. parts of the Peloponnesus by invasion and conquest from the north. At the beginning of the Olympiads, Sparta, afterward the leading Doric state, was of inconsiderable importance, and her territory hardly more than the valley of the Eurotas; but her military and civil institutions, as established by the constitution of Lycurgus, gradually raised the state to a foremost place among the commonwealths of Greece. The date of the Spartan lawgiver is doubtful, but it is generally placed within the century preceding the era of the Olympiads. His ordinances, called *rhetra*, wrought great changes in the constitution of society, and produced results that acted powerfully on the course of Greek history. (See LYCURGUS, and SPARTA.) Sparta became the mistress of the greater part of the Peloponnesus by subduing the Messenians, Arcadians, and Argives. The two wars against the Messenians were the most important and obstinate; they have also a special literary interest, on account of the

poems of Tyrtæus. The first Messenian war grew out of private quarrels. It occurred about 743 B. C., and, having lasted about 20 years, ended with the complete subjection of the Messenians, who were compelled to abandon their country, and were reduced to the condition of helots or slaves. About 38 years later (685), the Messenians, under the lead of the heroic Aristomenes, took up arms, and were supported by the Argives, Arcadians, Sicyonians, and Pisatans; while the Corinthians lent aid to Sparta. At first the fortunes of war were adverse to the Spartans; but though they suffered several bloody defeats from Aristomenes, they persevered until the Messenians became a second time the serfs of the Spartans (668). In the course of the following century the Spartans extended their conquests over the greater part of Arcadia, and annexed the large Argive territory of Cynuria. In the middle of the 6th century B. C. Sparta had become the most powerful of the states of Greece. She was distinguished politically from the others by retaining the form of a royal government, royalty having become extinct everywhere else at an early period of the Olympic era. In some of the states the king became an archon for life; in others the royal house was set aside, and one of the nobles selected, under the title of *prytanis*, or president, and holding office for a limited time. This was substantially a change from monarchy to oligarchy, since the powers of government were limited to the members of the old nobility, who possessed the greater part of the land. These oligarchies were overthrown in many of the Greek states by the rise to power of able and ambitious men, called by the Greeks tyrants. The early significance of this word was limited to the irregular methods by which power was attained, and not extended to the severity with which it was administered. Though the actual government of the tyrants was oppressive for the most part, yet some of them were among the wisest men and the best rulers of the Greeks. The period of the tyrannies was about 150 years, from 650 to 500. The most celebrated of these rulers were the tyrants of Sicyon, whose rule lasted 100 years, ending with Clisthenes (560); those of Corinth, beginning with Cypselus, including the great Periander, and ending with Psammetichus, about 581; and Theagenes, tyrant of Megara. A similar political condition prevailed in most of the other Grecian states in the 7th and 6th centuries. In Athens, in the legendary period, the kingly power terminated with Codrus, and was succeeded by the office of archon, at first limited to the royal family and held for life, then held for ten years, and finally thrown open to the whole body of the nobles, the number of archons increased to nine, and the period of office reduced to one year. With this last change the authentic history of Athens commences, about 683 B. C. (See ATHENS.) The legislation of Draco dates about 624, and the archonship and legislation of Solon 594.

The adoption of his constitution, and the subsequent modification of it by Clisthenes, reacting upon the original tendencies of the Ionian race to a free intellectual and political development, produced the results in letters, art, philosophy, political science, and popular eloquence, which so brilliantly distinguish the history of the Athenian commonwealth. But even in Athens a tyranny arose. Pisistratus was twice expelled, but he and his family ruled Athens with moderation, and administered the government through the Solonian institutions, until the assassination of Hipparchus converted his surviving brother Hippias into a despotic oppressor. The tyranny of the Pisistratidæ lasted about 50 years. The expulsion of Hippias was followed immediately by the popular changes in the constitution introduced by Clisthenes. The progress of Athens under the impulse of such wise and equal institutions excited the jealousy of Sparta, who made several unsuccessful attempts to overthrow the democracy. Besides the colonies in Asia Minor already mentioned, the Greeks extended their colonial system to Italy, Sicily, Gaul, Spain, Africa, and, in the north, to Epirus, Macedonia, Thrace, and the coasts of the Euxine. The Asiatic colonies were the oldest, and among them literature and the arts first developed themselves. The settlements in Italy and Sicily began about 735 B. C. The settlements in Egypt and Cyrene were commenced about a century later. About 700 the island of Coreyra was settled by Corinthian colonists, and other settlements were soon afterward made on the neighboring islands and the opposite coast; so that at the beginning of the 6th century the Hellenic race, in extent of territory and resources, was far the most powerful in the European world.—We have now reached the period when the Hellenic and barbaric races were preparing for an organized conflict. The Greeks of Asia Minor had been subjected by Croesus, king of Lydia, and were afterward ruled by Cyrus, the founder of the Persian empire. Darius, son of Hystaspes, ascended the Persian throne in 521 B. C. The revolt of the Ionian colonies from the Persian rule commenced effectively about 501, and the mother country was appealed to for aid. The Athenians voted to send a squadron of 20 ships, which, Herodotus says, “were the beginners of evil both to Greeks and barbarians.” In the following year Sardis was captured and burned by the Greeks under Aristagoras, and the revolt extended far and wide. Measures were speedily taken to suppress it. The capture of Miletus and the defeat of the Ionian fleet at Lade completed the subjection of Ionia (494). This event put an end to the ancient prosperity of Ionia. Darius made preparations to follow up its reduction by the conquest of Greece itself. Placing a large armament under the command of Mardonius, his son-in-law, he sent him across the Hellespont; but the destruction of the accompanying fleet, while attempting to double the

promontory of Athos, by a hurricane, and the slaughter of a large portion of the land force by the Brygians, a Thracian tribe, forced him to return to Persia. This was the first Persian expedition to Greece (492). The Persian monarch, stimulated by Hippias, the exiled despot of Athens, made preparations on a large scale, and in 490 assembled a mighty army in Cilicia, and a fleet of 600 galleys, with horse transports. The command was given to Datis and Artaphernes. Embarking with their forces, they sailed directly across the Ægean, reduced the Cyclades, took Eretria in Eubœa after a siege of six days, razed the city, and put the inhabitants in chains. In a few days they crossed to Attica, and landed on the plain of Marathon. The Athenians, warned of their approach, made preparations to receive them, and though opposed by a force more than five times as great as their own, and aided only by 1,000 Platæans, they attacked the Persian army in the open field, Miltiades commanding, and won over it one of the most famous victories in history. (See MARATHON.) The Persians fled to their ships, which were stationed in lines near the shore. They lost 6,400 men, the Athenians 192. The resentment of Darius, when he received the news of the defeat at Marathon, knew no bounds. He resolved to collect the forces of his empire, and to lead them himself against Athens. Three years were occupied in making preparations on a gigantic scale; but his death postponed the threatened invasion. Xerxes, his son and successor, influenced by Mardonius, who was eager to retrieve his reputation, resolved to prosecute the plan of conquest, and to collect forces on a still more magnificent scale. Four years more were occupied with preparations. Troops from 46 different nations were assembled; a large fleet furnished by the subject maritime nations was collected; immense stores of provisions were deposited at stations along the intended line of march; a bridge was constructed across the Hellespont, and a canal cut through the narrow neck that joins the peninsula of Athos to the mainland. The bridge having been swept away by a storm, Xerxes caused two to be built in its place, one for the army and one for the baggage and beasts of burden. The preparations were completed in 481, and in the spring of 480 the march began, from Sardis to the Hellespont, where the army crossed the bridge, and approached Greece along the coast of Thrace. According to Herodotus, the military and naval forces amounted to 2,317,610, besides the accessories from the native tribes; so that when Xerxes reached Thermopylæ his army consisted of more than 2,500,000 fighting men, or including attendants, if Herodotus is to be believed, of more than 5,000,000. Though these statements are incredible, the extensive preparations made for years give us reason to believe that the army of Xerxes was one of the largest ever assembled. To make arrange-

ments to resist this mighty invasion, a congress of deputies from the Greek states was summoned to meet at the isthmus of Corinth. The Athenians and Spartans attempted to unite them for the common defence; but the terror inspired by the Persian hosts was so great that many submitted at once, and others refused to take part in the congress. The only people N. and E. of the isthmus who dared to defend the country were the Athenians, Phocians, Plateans, and Thespians. The Athenians gave the command of the forces by sea and land to the Spartans, although they furnished two thirds of the fleet. It was at first decided to make stand against the invaders at Tempe, the celebrated and beautiful valley between Mts. Olympus and Ossa, through which the Peneus flows; but this was found impracticable. The pass of Thermopylæ, a narrow defile between the mountains of Ceta and the Maliae gulf, was finally occupied by Leonidas, the Spartan king, with a detachment of 300 Spartan citizens and several thousand other Peloponnesians. These, with the troops of the Thespians, Thebans, and Phocians, in all about 5,000 men, prepared to hold the pass against the innumerable host of the Persians. The heroic struggle which followed is one of the best known incidents of Grecian history (see THERMOPYLÆ); but it was unsuccessful, and nothing now intervened to prevent the march of the Persians upon Athens. The naval battle of Artemisium, at the N. extremity of Eubœa, took place about the same time as that of Thermopylæ. The Greek fleet on the following day received a reinforcement of 53 Athenian ships. Another battle was fought, in which the Persians lost the greater number of ships and men; but the Greeks, unable to renew the combat, and learning that Xerxes was in possession of Thermopylæ, sailed down the Eubœan straits, rounded the headland of Sunium, and anchored in the straits of Salamis. The Athenians, dismayed at the prospect of the march of Xerxes upon the city, decided to remove with the help of the fleet to the neighboring island of Salamis. A few only remained in possession of the Acropolis, awaiting the Persians. On their arrival the Persians took post on the hill of Mars, and with some difficulty succeeded in taking the Acropolis and dislodging its defenders. The city was given a prey to the flames. The fleet at the same time made its appearance in the bay of Phalerum. The dissensions among the Grecian commanders came near producing fatal results, but Themistocles, partly by his personal influence, and partly by stratagem, prevented the separation of the fleet. The banished Aristides joined the fleet and communicated the information that the Persians were in possession of the N. W. entrance into the bay of Eleusis, thus completely surrounding the fleet of the Greeks, still lying in the bay of Salamis. Nothing was left but to fight. Early in the morning the Greeks advanced

from the shore of Salamis to attack the Persian line, stretching along the opposite coast of Attica as far as the eye could reach. The result of the battle was a great victory. The Greeks lost 40 ships, and the Persians 200, besides those which were taken with their crews. Xerxes, who surveyed the battle from a throne erected on the W. slope of Mt. Ægaleus, immediately consulted his personal safety by flight, through Boeotia and Thessaly, to the Hellespont, and crossing over to Asia by the aid of his fleet (his bridge of boats had been washed away), he returned to his capital. Mardonius was left in command of the army, but thought it prudent to postpone further operations until spring. On the same day with the battle of Salamis (according to Herodotus), the Sicilian Greeks, commanded by Gelon, gained a great victory over the Carthaginians, under the command of Hamilcar, at Himera. Before opening a fresh campaign in the spring, Mardonius made an attempt to detach the Athenians from the cause of Greece. Failing in this, he marched upon Athens, and occupied it a second time (479), compelling the citizens to move again to Salamis. Ambassadors were sent to Sparta, and after some delay a considerable force was sent into the field by the Lacedæmonians and the Peloponnesian states. Upon learning these measures Mardonius withdrew into Boeotia, and took up a position on the left bank of the Asopus near the town of Platæa. The Greek army, now amounting to 110,000 men, moved from Eleusis, and after several days of manœuvring, with skirmishes of cavalry between the outposts, fought the battle of Platæa, defeated the Persians, stormed their camp, and took an immense amount of booty. Mardonius was slain. At the same time the Persian fleet was utterly defeated at Mycale, a promontory near Miletus, by the Spartan Leotychides and the Athenian Xanthippus, who had crossed the Ægean sea in pursuit. These decisive events put an end to the Persian invasions of Greece. In the following year a fleet was sent, under the command of the Spartan regent Pausanias, to expel the Persians from Cyprus and the ports in Thrace, including Byzantium, which they still held. The expedition was successful, though it gave rise to the treacherous action of Pausanias, which, if it had not been promptly discovered and punished, might have cost the Greeks much that they had gained. The noble conduct of Athens during the Persian war gave her at their close a commanding position in the affairs of Greece. A league was formed, entitled the confederacy of Delos, because the deputies were to meet in synod there, at the temple of Apollo and Artemis, the general object being to secure the common defence against Persian aggression by the maritime power of Athens. The members of the league were to pay an annual amount, the assessment of which was intrusted to Aristides, whose integrity of character had given him the surname of the Just. The officers

charged with the administration of the common fund were appointed by the Athenians, and bore the name of *Hellenotamiai*. The city was rebuilt on a larger scale than before, and rapidly became the leading maritime and commercial power of Greece. It was strongly fortified, and the harbors of Piræus and Munychia were protected by a wall along their shores, and chains supported by towers at their entrance, and the fleet was annually increased by the addition of 20 triremes, under the advice of Themistocles; the constitution was also made still more popular. The rising prosperity of the Athenian state, even at this early period, began to excite the jealousy of Sparta, which attempted to interfere, but was checked by the superior craft of Themistocles. In 465, however, an expedition against Thasos presented the opportunity for a hostile manifestation on the part of the Spartans. The Thasians applied to the Lacedæmonians, who agreed to make a diversion in their favor by invading Attica; a promise they were only prevented from keeping by an earthquake in 464, which laid their capital in ruins, destroyed more than 20,000 citizens, and encouraged the helots to revolt. The Messenians, taking advantage of these calamities which had befallen their ancient oppressors, fortified themselves on Mt. Ithome, and held out more than two years, when the Lacedæmonians finally dislodged them with the assistance of their allies. Athens continued to increase in power, while Sparta was declining. The foreign policy of Pericles, now chief of the Athenian state, carried out the political principles of Themistocles, and aimed to render this the leading power of Greece. In 458-457 he began the long walls, which connected Piræus and Phalerum with Athens, thus enclosing the city and the ports in one uninterrupted series of fortifications. The Spartans, whose jealousy of Athens was still further increased, endeavored to check her power by marching into Boeotia and increasing the power of Thebes; and in consequence of intrigues of the oligarchical party in Athens, they sent an army to Tanagra, on the borders of Attica. A battle followed, in which the Lacedæmonians had the advantage, but were not decisively victorious. In 456 the battle of Enophyta was fought, and Thebes and other Boeotian towns fell under the dominion of Athens. Phocis and Locris came next. In 455 the long walls were completed, and Ægina reduced to the condition of a tributary ally. In 452 the Lacedæmonians concluded a five years' truce with Athens, which was soon after followed by the pacification known as the "peace of Cimon." (See CIMON.) The custody of the common fund at Delos was now transferred to Athens, which had rapidly become the imperial head instead of an equal member of the league. The height of her power may be dated about 448. In the following year she lost her ascendancy in Boeotia, Phocis, and Locris, and a revolt broke out in

Eubœa and Megara. Eubœa, however, was soon reduced by Pericles; but Athens never recovered her other possessions, while a formidable confederacy was organizing against her in the Peloponnesus. In 445 the Athenians concluded a truce with Sparta and her allies for 30 years. Pericles still pursued his policy of aggrandizing and embellishing Athens; but for a time he had a powerful opponent in Thucydides, the leader of the conservative party, whose banishment soon afterward left Pericles almost the undisputed master of the state. It was at this period that the city was adorned with the grand works of statuary, architecture, and painting, which made her not only the glory of Greece but the school of the world. Pericles enlarged the empire of Athens by colonization, from the shores of the Euxine to Italy. He increased the sum of the contributions to more than double the original amount. The Athenians now considered themselves the sovereign head of the league. All the important questions, all public suits, and all private suits in which an Athenian was one of the parties, were decided at Athens; and the city began to be called "the despot." The Peloponnesian war had its remote origin in the jealousies that had long been growing between Sparta and Athens, which were strengthened by the antagonism between the Ionian and Dorian institutions, the former represented by Athens and the latter by Sparta; but the immediate occasion of the commencement of this ruinous conflict was a quarrel between Corinth and her former colony Corcyra, in relation to Epidamnus, a colony established by the latter on the coast of Illyria. The Corcyraean fleet defeated the Corinthians in a battle near Actium, in 435. The Corinthians spent two years in preparing to avenge this disgrace; and the Corcyraeans applied to Athens for aid. Under the counsels of Pericles, who foresaw that war was inevitable in the end, a defensive alliance was concluded with Corcyra, and a fleet of 10 triremes was despatched for the support of that island in case of its territory being invaded. A naval battle took place off the coast of Epirus in 432, in which the Corinthians were victorious. At first the victors resolved to renew the attack and effect a landing at Corcyra; but the appearance of 20 Athenian sail in the distance caused them to change their purpose, and they returned to Corinth with about 1,050 prisoners, 800 of whom were sold as slaves, and the remainder, who belonged to the first families of Corcyra, were kept as hostages. The Corinthians, offended with the part taken by the Athenians in these affairs, assisted the Potidæans, their colonists, now tributary to Athens, who had been stirred up by Perdiccas, king of Macedon, to revolt against the imperial city. A general meeting of the Peloponnesian confederacy was called at Sparta, and deputies from the several states appeared (432). Their charges against Athens were answered by an ambassador who happened to be resident

there at the time on other business; but a large majority of the assembly voted for war. Before carrying the vote into execution, the Spartans made several demands upon the Athenians: 1, the banishment of the Alcmaeonidae, among whom Pericles himself was included; 2, the withdrawal of the Athenian troops from Potidæa, the restoration of independence to Ægina, and the repeal of a decree against Megara; 3, a recognition of the independence of the other Grecian states. Pericles in a powerful speech argued that no concessions could avert the war, and an answer in accordance with his views was returned. Hostilities were commenced the next year by an attack of the Thebans upon Plataea. The war, being thus openly begun, soon drew into its vortex nearly all the states of Greece. On the side of Sparta were ranged the whole Peloponnesus (except Argos and Achaia), the Megarians, Bœotians, Phocians, Opuntian Locrians, Ambraciotes, Leucadians, and Anaetorians. The Dorian cities of Italy and Sicily were expected to furnish a fleet, and it was even contemplated to invite the Persian king to send a Phœnician squadron against Athens. The allies of the Athenians were the Chians, Lesbians, Coreyæans, Zacynthians, and afterward the Cephallenians; the tributary cities on the coasts of Thrace and Asia Minor, and the islands N. of Crete, except Melos and Thera. Archidamus, the Spartan king, leading a force of from 60,000 to 100,000 men, marched from the isthmus, where they had assembled immediately after the attack upon Plataea, crossed the Attic border, and entered the Thriasian plain early in the summer of 431. Pericles collected the inhabitants of Attica within the walls of the city, and abandoned the country to the ravages of the invaders, while he sent a fleet to lay waste the coasts of the Peloponnesus. It was not before the end of the summer that Archidamus retired from Attica and disbanded his army. The second invasion of Attica by the Lacedæmonians took place the next year. The sufferings of the people were terribly increased by the plague of Athens, of which Thucydides, one of the few of those attacked who survived, gives an accurate and powerful description. The demoralizing effects of the despair produced by this mysterious disease were worse than the physical sufferings. It was estimated that not less than a fourth of the population was carried off. In this extraordinary and calamitous state of affairs an outcry was raised against Pericles, as the author of the public misfortunes. On his return from a naval expedition against the Peloponnesus, he was accused by Cleon, a rising demagogue, of peculation, brought to trial, and condemned to pay a fine. But the popular feeling veering about, he regained his influence, and was reëlected general. Soon after, however, he was attacked by the disease, which had already carried off his sister and his two sons Xanthippus and Paralus, and died of a lingering fever, which supervened upon the plague, and, in the weakened state

of his constitution, proved fatal. The death of Pericles struck a deadly blow to the Athenian cause. The men who seized the control of the state were greatly his inferiors in moral character and all statesmanlike qualities. In the second year of the war the Lacedæmonians made some attempts and did some harm to the Athenian possessions by sea. In the following winter Potidæa capitulated, having been instigated to revolt by the Lacedæmonians, and the territory was occupied by colonists from Athens. Two invasions were made in 429; and the memorable siege of Plataea, which ended two years later, commenced. After the surrender the Lacedæmonians cruelly put to death every man who fell into their hands, and utterly destroyed the city. In the same year Phormio gained several naval victories for Athens in the Corinthian gulf. In 428 Attica was again invaded. Mitylene, the capital of Lesbos, revolted, and a fleet was despatched against it. The aid of the Lacedæmonians was invoked, and succors were promised; but delays occurring in sending them, the party of the Mityleneans favorable to Athenian supremacy opened negotiations with Paches, the Athenian commander, and a capitulation was agreed upon. The leaders of the revolt were sent to Athens, where a remarkable debate was held on the question of putting the whole body of the Mityleneans to death. Cleon's savage proposal of a general massacre was at first carried by a small majority, and a trireme was despatched with orders to Paches to put it immediately into execution. But the cooler second thoughts of the people in the assembly of the following day led to a reversal of the decree; a second trireme, rowed by oarsmen stimulated by the promise of large rewards, being sent with counter orders, happily arrived in season to arrest the execution of the decree. To this period belong the bloody feuds at Coreyra, of which Thucydides has drawn a masterly picture. The year 426 was marked by calamities of another kind—by floods, earthquakes, and the reappearance of the plague at Athens. In 425 the Athenians established a garrison at Pylos, the modern Navarino; an act which recalled the Peloponnesian fleet from Coreyra, and the army from Attica, where they had been only 15 days. An assault was made, led by Brasidas, with the intent to expel the Athenians, but it was not successful; and while the Lacedæmonians were preparing to renew it, the Athenian fleet entered the port, and in the battle that ensued gained a decisive victory. The Athenians now blockaded the Lacedæmonians, shut up on the little island of Sphacteria. The besieged were reduced to such straits that an armistice was solicited to enable the Lacedæmonians to send to Athens and sue for peace. The Athenian assembly, under the influence of Cleon, insisting on extravagant terms, the war was resumed. Demosthenes, the Athenian general, not succeeding as quickly as was hoped in reducing the garrison, sent to Athens for further assis-

tance, communicating at the same time intelligence of the actual state of the siege. Cleon vehemently attacked the conductors of the war, and boastfully declared that if he were general the island would be captured without delay. Unexpectedly to him, the people took him at his word. Unable to decline the honor thrust upon him, Cleon departed to the scene of his command; and, by availing himself of the preparations Demosthenes had already made, he was able to keep his promise, and arrived at Athens with the Spartan prisoners in 20 days after his departure. The Athenian fleet, after the victory, proceeded to Corcyra, and witnessed another series of political massacres, without attempting to prevent them. In 424 the Athenians were defeated at Delium, and met with severe losses in Thrace, while Nicias was reducing Cythera and garrisoning its principal towns. The Lacedæmonians added to the customary atrocities of war the murder of 2,000 helots whom they pretended to emancipate. The Athenians sent expeditions against Megara and Bœotia, the former of which was only partially successful, and the latter a disastrous failure—the defeat of Delium, already mentioned. These reverses, especially the defeats in Thrace, disheartened the Athenians. In 423 a truce was concluded for a year, with a view to a permanent peace. But the negotiations were interrupted by the revolt of Scione to Brasidas, and hostilities in that quarter were renewed. In 422 Cleon was despatched to the north, with a fleet and army; but he showed his incompetency to encounter Brasidas, and fell in a disgraceful retreat before that general from Amphipolis, where Brasidas himself also fell. In 421 the peace of Nicias was concluded, followed by an alliance offensive and defensive between Athens and Sparta. An attempt was soon made to form a new confederacy under the leadership of Argos, excluding Athens and Sparta. Difficulties sprang up between these two states, which were fomented by Alcibiades, who had now risen to influence in Athens, and bore a private grudge against Sparta; he advocated a league with Argos, and resorted to tricks and intrigues to carry his point. Accordingly in 420 a treaty for 100 years was made with Argos, Elis, and Mantinea. In 418, in consequence of these events, and the insolence of Alcibiades, the Lacedæmonians sent an army into the territory of Argos, and the battle of Mantinea crowned the Spartan arms with victory over the Athenian and Argive forces. Civil discords and revolutions and counter revolutions followed at Argos. In this same year the Athenians conquered the island of Melos, and, on the proposal of Alcibiades, put the men to death, sold the women and children into slavery, and established an Athenian colony on the island.—The feuds that distracted Greece broke out with baneful effect in the Sicilian and Italian colonies. This led to the intervention of Athens. In 427 Gorgias of Leontini was sent to Athens to ask

succor for his countrymen. A squadron of 20 ships was immediately sent, and in 425 another of 40; but the Sicilians were alarmed, and the expeditions were without effect. Another application was made in 422, but unsuccessfully. In 416 Segesta, having a quarrel with Selinus, sent an embassy for aid, the Syracusans having taken sides with the Selinuntines. Alcibiades supported the demands of the Segestans, in opposition to the policy of Nicias and his party. It was decided to send a fleet of 60 triremes, under the command of Nicias, Alcibiades, and Lamachus, in the expectation not only of assisting Segesta and Leontini, but of extending the power of Athens over all Sicily. Three months were spent in making preparations on a grand scale, and the greatest enthusiasm prevailed. Just as the armament was on the point of sailing, the superstitious terrors of the Athenians were roused by the mutilation of the Hermæ, or square pillars surmounted with the head of Hermes, standing in the streets and public squares, and the public suspicion fell upon Alcibiades as the author of the sacrilege. This crime, together with the profanation of the Eleusinian mysteries by a private representation, was charged upon him by Pythonicus, in the public assembly. But instead of an immediate investigation, his political enemies caused it to be postponed till his return; and the fleet departed from the Piræus (415). The rendezvous was appointed to be held at Corcyra, whence the combined fleet of the Athenians and their allies sailed for the Japygian promontory, and thence to Rhegium, where they awaited the return of the fast-sailing triremes which had preceded the main body to Segesta. The reports brought back were not very encouraging, and there was a difference of opinion among the generals. Alcibiades was met at Catana by a summons to return to Athens, and take his trial on the charge of profaning the Eleusinian mysteries. The state ship *Salaminia* brought the order; but on the way home Alcibiades escaped. The trial went on according to Athenian usage, and though absent, he was condemned to death. After some months' delay Nicias commenced operations against Syracuse, and having gained a victory retired to Catana, and afterward to Naxos, into winter quarters. The Syracusans occupied the winter in preparations for defence. In the following spring (414) the siege of Syracuse was commenced. Just as the Syracusans were on the point of surrendering, Gylippus the Spartan arrived in Sicily with a small force, and landing at Himera, on the N. coast, levied an army, and marched upon the city. This changed the face of affairs, and put to flight all thoughts of surrender. Two naval battles were fought in the great harbor. In the first the Athenians gained the advantage, but they were defeated in the second. Meantime, the Lacedæmonians at home had ravaged the Argive territory, and the Athenians had sent a fleet against Epidaurus. In 413 the Lacedæ-

monians invaded Attica and established themselves in Decelea, acting under the advice of Alcibiades, who had passed over from Italy to the Peloponnesus. Yet the Athenians resolved not only to ravage the coast of Laconia, but to send reinforcements to Sicily. They accordingly despatched 75 triremes, under the command of Demosthenes, with 5,000 heavy-armed and a large body of light-armed troops. After several unsuccessful attempts upon the outer positions, and when sickness broke out among the troops, it was found necessary to withdraw from the great harbor; but an eclipse of the moon, occurring on the appointed night, prevented their departure. This fatal delay gave the Syracusans an opportunity of attacking them by land and sea. Gylippus suffered a repulse by land; but the Athenian fleet was defeated, and Eurymedon the commander slain. The entrance to the harbor was blocked up. A terrible battle was immediately fought, the Athenian fleet driven ashore, their crews leaping out, and flying to the camp for refuge. Escape by sea was now cut off; the ships were all abandoned to the enemy; and in attempting to retreat by land, the divisions of the army, greatly reduced by their sufferings, were successively surrounded and made prisoners. The captives were set to work in the stone quarries of Achradina and Epipolæ, and Nicias and Demosthenes were doomed to death. The calamitous close of this expedition overwhelmed the Athenians with sorrow and despair, and the popular fury vented itself on those who had proposed or encouraged the enterprise. The occupation of Decelea by the Lacedæmonians still harassed the city, keeping it almost in a state of siege. The consequences soon began to be felt in the defection of the allies and subjects, who were encouraged and aided by Sparta in throwing off the yoke. Alcibiades was actively engaged in stirring up the spirit of revolt. But the Athenians were not long in taking measures to remedy as well as they could these terrible disasters. They appointed a committee of public safety, under the name of *probuli*, commenced a new fleet, and fortified Sunium. Acting under the advice of Alcibiades, the Lacedæmonians sent a fleet in aid of the Chians. The movement was successful, and other cities and islands on the Asiatic coast followed the example of revolt. The Athenians now appropriated the fund of 1,000 talents reserved by Pericles to fitting out a fleet against the Chians; but the revolt continued to extend, embracing Teos, Lesbos, and Miletus. The Samians remained faithful, and Samos became the headquarters of the Athenian fleet. Several victories soon crowned the changing fortunes of Athens. By this time Alcibiades, whose manners also were offensive to the Spartans, excited their distrust by his intrigues with the Persians. At length he brought matters to such a pass that the Athenians, pressed by the necessities of their condition, agreed to restore him, and to change the constitution to

an oligarchy, on condition of aid from Persia. A revolution was effected, and the government of the 400 established, with the power of convening a select body of 5,000 citizens whenever they saw fit; but the expected aid from Persia was not received. The 400 opened negotiations with Agis, the Spartan king. But dissensions broke out, a counter revolution was partially successful, and the democratic constitution was maintained in Samos. The Lacedæmonians failed to seize the opportunity of striking a blow by taking the Piræus, but the Athenian fleet was defeated at Eretria in Eubœa. The old constitution was finally restored, and several leaders of the oligarchical party, among whom was Antiphon the orator, were put to death. From this period, although the Lacedæmonians still held possession of Decelea, the war was mainly carried on by sea. An attempt was made by Mindarus, the Lacedæmonian commander, to effect a revolt of the Athenian dependencies in the neighborhood of the Hellespont. Thrasyllus the Athenian followed him, and the battle of Cynossema, in which the Athenians were victorious, was fought (411); the shattered remains of the Lacedæmonian fleet were wrecked off Mt. Athos. Another battle was soon after fought near Abydos, which was decided in favor of the Athenians by the arrival of Alcibiades from Samos. A third battle was fought near Cyzicus the next year, and, the Spartan running his ships ashore, Mindarus was slain, the fleet taken, and the Athenians became again masters of the Propontis. The Lacedæmonians now offered peace; but the Athenians, elated by their recent victories, and influenced by the harangues of Cleophon, an influential demagogue, rejected the terms. In the two following years the Athenians recovered Selymbria and Byzantium, chiefly through the active services of Alcibiades; and in 407, after an exile of eight years, he was fully restored, the sentence against him was annulled, and he was placed with unlimited powers at the head of all the forces of the republic, by land and sea. In the mean time Cyrus, the younger son of Darius II., was sent down as satrap to the provinces of Lydia, Phrygia, and Cappadocia, and the able Lysander was sent from Sparta to take command of the Lacedæmonian fleet. They resolved to act in concert. Alcibiades sailed from Athens to Andros, where he left a part of the fleet under Conon to prosecute the siege, and proceeded to Samos. He attempted to raise money by force; and while absent from Samos on this business his pilot Antiochus, contrary to his orders, hazarded a battle, and sustained a defeat. These events, and the profligate conduct of Alcibiades, lost him the confidence of the Athenians, and he was deprived of his command. Ten new generals, the chief of whom was Conon, were appointed to supersede him. A battle was fought between Conon and Callicratidas, the successor of Lysander, in the harbor of Mitylene, in which Co-

non lost 30 ships; but the Athenians, learning this disaster, despatched with incredible speed 110 triremes, and a great battle followed near the little islands called Arginusæ, in which the Lacedæmonians lost 77 vessels (406). The generals were brought to trial at Athens on a charge of not collecting the bodies of the dead for burial, and six of them were executed in a moment of popular frenzy. Socrates, who happened to be one of the presiding officers at the public assembly, protested against the proceeding and refused to put the vote; but the next day a more pliant officer went through the form, and the great crime was consummated. Callieratidas having perished in the battle, Lysander was reinstated in the command in 405; and proceeding to the Hellespont, he took up his station at Abydos. The Athenians, hearing of this movement, also sailed to Ægospotami near Lampsacus, which Lysander was besieging. After five days of manœuvring, the momentous battle was fought which put an end to the war by the ruin of Athens. Conon escaped with only 8 or 10 ships, out of 180; 3,000 or 4,000 Athenian prisoners were put to death, with the generals. It was in September, 405, that Lysander received the submission of the Athenian cities, and established in them oligarchies of ten (decarchies). He reached Athens in November, and the Peloponnesian army marched into Attica, encamping near the city, on the grounds of the academy. After three months of dreadful sufferings by famine, the Athenians surrendered; and in March, 404, Lysander took formal possession of the city. The conditions of the surrender were executed; the walls and fortifications were dismantled to the music of the flute; the arsenals were destroyed, the ships on the stocks burned, and all the fleet except 12 triremes carried off by Lysander. The government of the thirty, called the thirty tyrants, was established, and Lysander, sailing to Samos, soon reduced that island, and then returned to Sparta loaded with honors. The government of the thirty soon made themselves feared and hated, establishing by their tyrannical and bloody acts a reign of terror. It is said that 1,500 persons were executed without trial. Alcibiades was included in the list of exiles; but he was put to death by Pharnabazus, the Persian satrap, in compliance with orders transmitted from Sparta to Lysander. The state of feeling in Greece soon began to turn against the Lacedæmonians. They had shown a grasping disposition, and Lysander, puffed up by his military successes, was haughty and tyrannical. Thrasybulus and other Athenian exiles ventured to seize the fortress at the pass of Phyle, on Mt. Parnes, and the thirty were repulsed in an attempt to dislodge them. The thirty, feeling their position insecure, resorted to still more atrocious and bloody means of perpetuating their power; whereupon Thrasybulus marched down to Piræus and occupied the hill of Munychia. The thirty, with the whole force at their com-

mand, attacked them; but Thrasybulus fell upon and defeated them, and slew 70, with Critias their leader. A new government of ten was established at Athens, and the aid of the Lacedæmonians was invoked. Pausanias, having superseded Lysander, led an army into Attica, and after several unimportant combats terms were agreed upon (403); the exiles were restored; the democracy was reestablished, with all the old administrative bodies; the acts of the thirty were annulled, and the old laws revised, and inscribed on the walls of the Pœcile Stoa, in the full Ionic alphabet of 24 letters, then for the first time introduced into the public records. In 401 occurred the episode of the Anabasis, or expedition of Cyrus the Younger, which is connected with the history of Greece by the circumstance that his army consisted in part of Greek mercenaries, and that Xenophon the historian served as volunteer, and conducted the Greek troops back to the sea, after the battle of Cunaxa.—The period following the downfall of Athens is that of the Spartan supremacy, which lasted 34 years, from 405 till the battle of Leuctra, 371, although her maritime power was greatly diminished by the battle of Cnidus, in 394. The conquest of Elis in 402 extended her power in the Peloponnesus; but she soon entered upon a course of degeneracy and decay. The intrigues of Lysander, and the large sums of gold and silver introduced into the country, tended to change and corrupt the ancient character of the Lacedæmonians, and to produce great inequalities in the condition of the citizens. Troubles soon broke out in Asia Minor, and a Lacedæmonian force under Thimbron was despatched to protect the Ionian cities against Tissaphernes, the Persian viceroy of Asia Minor. He was succeeded by Dercyllidas. In 397, after several encounters, an armistice was agreed upon; but Pharnabazus, the rival of Tissaphernes, seized the opportunity to organize a fleet, which was placed under the command of Conon, who since the defeat at Ægospotami had lived under the protection of Evagoras, prince of Salamis in Cyprus. Agesilaus invaded Asia with a powerful army in 396, and in 395 marched upon Sardis. Tissaphernes was put to death, through the influence of the queen mother Parysatis, and his successor Tithraustes made an armistice of six months with Agesilaus, who in the mean time was appointed to the command of the Lacedæmonian fleet in addition to that of the army. A new fleet of 120 triremes, under the command of Pisander, was sent out by the Lacedæmonians the following year. In August, 394, the great battle of Cnidus was fought, in which more than half of the Lacedæmonian fleet was destroyed, and Pisander fell. In the mean while discontents in Greece itself with the Spartan power were eagerly fomented by Persian agents, and hostilities breaking out between Sparta and Thebes, Athens was called in by the latter. Lysander was slain in an action at Haliartus (395), and

Pausanias was obliged to retreat. An alliance was formed against Sparta between Athens, Corinth, Argos, and Thebes, and many other states soon joined it. A meeting was held in 394 at Corinth, and in this alarming state of affairs Agesilaus was recalled from Asia. The battle of Corinth, in which the Lacedæmonians gained the victory, was fought in July, 394, nearly at the same time with the battle of Cnidus. Agesilaus received the news at Amphipolis, on his way from Asia; and on the frontiers of Phocis and Bœotia he heard of the defeat and death of Pisander at Cnidus. Pressing forward, he met the confederate army at Coronea, where a terrible conflict took place, ending in a victory, though not a decisive one, for Agesilaus. The defeat of Cnidus cost the Spartans the maritime supremacy they had acquired at Ægospotami. The Spartan harmosts (governors) were expelled from the islands. In 393 the coast of Laconia was ravaged by Conon and Pharnabazus; the long walls of Athens and the fortifications of Piræus were rebuilt, and Athens had regained something of her former power, by laying again the foundations of maritime supremacy. The war continued during the following year, in the neighborhood of Corinth, the Spartans making their headquarters at Sicyon, and ravaging the Corinthian plain, besides gaining the advantage in several skirmishes. The triumphant career of the Spartans was interrupted by the victories of Iphicrates, an Athenian commander of a body of mercenaries. Agesilaus returned stealthily to Sparta, and many places in the Corinthian territory were retaken by his aid. The Lacedæmonians sent Antalcidas to negotiate with the Persians, in the hope of regaining their good will; and Tiribazus secretly furnished the Spartans with money, and treacherously seized Conon, who now disappears from history. In 389 a fleet of 40 triremes was despatched from Athens to Asia Minor, under Thrasybulus; but after reestablishing the Athenian supremacy in several places on the Hellespont, he was surprised and slain at Aspendus. Anaxibius was sent from Sparta to succeed Dercyllidas as governor of Abydos, and Iphicrates was despatched from Athens. He attacked Anaxibius among the passes of Ida, defeated his army, and slew him with 12 other harmosts, thus giving the Athenians again the mastery of the Hellespont. But the Æginetans began to infest the trade of Athens, and the Lacedæmonians, under Teleutias, took Piræus by surprise, and carried off a considerable amount of booty. In 387 the treaty of Antalcidas was concluded, on terms that were denounced by the Athenian writers a few years later as most disgraceful, but the deputies from the states felt obliged to yield their assent. In substance it provided that the cities of Asia and the islands of Clazomenæ and Cyprus should belong to Persia, and, with the exception of Lemnos, Imbros, and Scyros, which were to remain to Athens, all the cities should be independent. Sparta now com-

menced a series of aggressions in Bœotia. Plataea was rebuilt for a Spartan outpost. Mantinea, against which Sparta owed a grudge, was reduced, dismantled, and placed under an oligarchy. In 383 the affairs of Olynthus, the centre of a powerful confederacy at the head of the Toronaic gulf, attracted the attention of Sparta; and Eudamidas was despatched to the defence of Acanthus and Apollonia, but his army was not sufficiently strong to take the field at once against the Olynthians. Another force was collected by Phœbidas, the brother of Eudamidas, and marched to Thebes, where they treacherously got possession of the Cadmea or citadel. The indignation which this act excited induced the Lacedæmonians to disavow it, and to dismiss Phœbidas; but they continued to occupy the citadel with a garrison, and Thebes was enrolled as a member of the Lacedæmonian confederacy. The war with Olynthus was closed in 379, with the capitulation of the city, and the dissolution of the league of which she was the head; a great misfortune, as the event proved, to Greece. In 379 a revolution was brought about at Thebes, chiefly by the young Pelopidas, who was living in exile at Athens, and who arranged a conspiracy with some of the leaders of the patriotic party at Thebes, which was carried into successful execution. The garrison capitulated, the exiles returned, and the revolution shook the influence of Sparta throughout Greece. Athens set vigorously to work to organize a new confederacy, and Thebes enrolled herself as one of the earliest members. A congress was held in Athens, and a large army and fleet voted. The war with Sparta was zealously prepared for. At Thebes the famous "sacred band" was formed, and Pelopidas and Epaminondas were actively engaged in organizing the war. Agesilaus marched from Sparta into the Bœotian territory, and laid waste the country, to the gates of Thebes; in the following year he conducted a second expedition, in which he received an injury that withdrew him from active service. The next expedition was accordingly conducted by Cleombrotus; he was forced to retreat by the Thebans, who had seized the passes of Cithæron. In 376 a Lacedæmonian fleet under Pollio was defeated by Chabrias the Athenian near Naxos; and Timotheus, another Athenian, son of Conon, sailed to the west of Greece, and gained over to Athens Cephallenia, Coreyra, and many of the Epirotes and Acarnanians. Dissatisfaction and jealousy sprung up among the confederates of Athens. Thebes was extending her dominion over the neighboring states, and in 375 Pelopidas gained a victory over the Lacedæmonians at Tegyra. In 374 the Thebans had completely expelled the Lacedæmonians from Bœotia, and menaced Phocis. The Athenians made with Sparta a peace which was immediately broken, and the successes of the Athenian army on the western coast of Greece so alarmed the Spartans that in 372 Antalcidas was again despatched to solicit the aid of Per-

sia. Fresh negotiations were opened, a congress was held in Sparta in 371, and the peace known as the peace of Callias was ratified by all except Epaminondas, the representative of Thebes. Hostilities between the Thebans and Lacedæmonians commenced almost immediately, and the great battle of Leuctra established the ascendancy of Thebes, while striking a destructive blow at the power of Sparta. Jason, the despot of Phæræ, joined the Thebans; but, instead of renewing the attack, he used his influence in effecting a truce by which the Lacedæmonians were allowed to withdraw from Boeotia. The Athenians, dreading the power of Thebes, now formed a new coalition, including most of the Peloponnesian states. In 370 Epaminondas entered the Peloponnesus, laid waste the valley of the Eurotas, built Megalopolis, which he peopled with Arcadians, and the town of Messene, on Mt. Ithome, recalling the exiled Messenians. Sparta applied to Athens for help, and an alliance was formed to prevent the Thebans from invading the Peloponnesus. But Epaminondas forced his way through the Oncean mountains, and joined his allies, though nothing of importance was accomplished, when both armies dispersed and returned home. In 368 Pelopidas led an expedition to Thessaly against Alexander, the despot of Phæræ; thence he marched into Macedonia, and made an alliance with Ptolemy, the regent, who gave hostages for the observance of the treaty, among whom was Philip, afterward the king of Macedon. Soon after this the Arcadians were defeated by the Lacedæmonians. Epaminondas entered the Peloponnesus again, in order to bring the Achæans, hitherto confederates of Sparta, into the Theban alliance. He succeeded; but a counter revolution was soon after effected, and the Achæan cities went back to Sparta. In 367-66, accompanied by deputies from their allies, Pelopidas proceeded to Susa on an embassy to the Persian court, and Thebes was declared to be the head of Greece, in spite of the opposition of the Athenians and Arcadians; but the Persian rescript was not received with favor even by the allies of Thebes. Pelopidas having been seized by Alexander of Phæræ, in a mission to Thessaly, an army was despatched for his rescue; and the troops, being in danger from the pursuit of the Thessalians and Athenians, called Epaminondas, who was serving in the ranks, to the command, and under him were safely brought back to Thebes. Epaminondas was restored to the command of the army by the people, and immediately undertook another expedition for the release of Pelopidas, which was entirely successful. The Athenians meantime sent a fleet into the Ægean sea under command of Timotheus, and took Samos, Potidæa, Pydna, Methone, and perhaps Olynthus. Thebes, jealous of the growing power of Athens, resolved to try her fortunes on the sea. Epaminondas told his countrymen that they must not be content until they had transferred the Propylæa of the Acropolis to the

Theban Cadmea. He appeared in 363 with a fleet of 100 triremes in the Hellespont; but he accomplished little, and this was the only maritime expedition undertaken by the Thebans. About the same time Pelopidas, leading an army against Alexander of Phæræ, defeated him at Cynoscephalæ, but was himself slain in the moment of victory. Alexander was compelled to limit himself to Phæræ, and to become a subject of Thebes. A war in the mean time was waged between Elis and Arcadia, and the presidency of the Olympic games was transferred from the Eleans to the Pisatans (364). The Eleans asserting their rights by force, the temple of the Olympian Jupiter was converted into a fortress. The Eleans were repulsed, but they afterward struck the 104th Olympiad out of the catalogue. In 362 Epaminondas undertook his last invasion of the Peloponnesus, in consequence of the acts of the Arcadians. He attempted to surprise Sparta; but though he entered the city, finding that his movements were anticipated, he retired. The hostile forces now concentrated in the plain between Tegea and Mantinea. A battle was fought, in which the Theban commander gained a great victory over the Mantineans and Lacedæmonians, but, while fighting in the foremost ranks, lost his own life. Peace was immediately afterward made, in accordance with his dying advice.—We now come to the Macedonian period, which closes the brilliant independent existence of the Grecian commonwealths. The wars of which we have given a rapid sketch exhausted the resources and demoralized the character of the Greeks, and prepared the way for any powerful neighbor to build up an empire on the ruins of Hellenic independence. For many years the princes of Macedon, claiming to be of Hellenic lineage, had been growing in power, though in the midst of barbarism. Philip, son of Amyntas II., was sent in his youth as a hostage to Thebes, and there acquired a taste for Greek literature, and learned the art of war as improved by Epaminondas. At the age of 23 (359) he became king of Macedon. In 358 he took Amphipolis after a siege, and thus came into collision with Athens, to which Amphipolis formerly belonged. He secured the good will of the Olynthians by taking Potidæa and bestowing it upon them. In the same year (356) Philip gained the prize in the chariot race at Olympia, and a victory over the Illyrians. Athens was occupied in the mean time with the social war—a war with her former allies, which commenced in 358, and ended in 355. The sacred war broke out near the same time between Phocis and Thebes, in the midst of which Philip began to interfere in the affairs of central Greece, assuming the character of defender of the god at Delphi. The Thessalian army was defeated near the gulf of Pagasæ in 352; but his march against Phocis was arrested at Thermopylæ by an Athenian force posted there. He then turned his arms northward to Thrace and the Cher-

sonesus. It was at this time that Demosthenes, penetrating the ambitious designs of Philip, came forward as his opponent; but little was done to check a danger which seemed so distant and uncertain, notwithstanding the orator's vehement appeals. In 350 Olynthus, alarmed at the encroachments of Philip, sent envoys to Athens to demand assistance; and their demand was supported by Demosthenes, in the three Olynthiac orations; but a strong party headed by Phocion opposed him. Philip prosecuted his schemes almost uninterruptedly until Olynthus fell into his power (347), betrayed by two of the leading citizens, Lasthenes and Euthycrates, and the Chalcidian peninsula became subject to Macedon. Demosthenes now put forth strenuous efforts to organize a confederacy of the Grecian states, but without success. Overtures were then made for reconciliation with Thebes, to which the sacred war had become burdensome and exhausting; and Philip, observing this tendency of things, and unwilling that such a combination of powerful states should take place, made advances to Athens. Ambassadors were despatched to Philip, among whom were Philocrates, the author of the measure, Demosthenes and Æschines, the orators, and Aristodemus, the actor. Some of the ambassadors were gained over to Philip's interest by bribery, as was charged by Demosthenes; and Philip immediately sent envoys to Athens, who arranged a treaty. A second embassy was sent from Athens to receive from Philip the oath of ratification, with instructions to proceed at once to him wherever he might be. Instead of this, they went to Pella, and remained there until his return from Thrace, where he was engaged in an expedition against Kersobleptes, an ally of the Athenians. The treaty was finally ratified at Pherræ, after nearly three months' delay; but the Phocians were excluded, and Philip immediately passed the defile of Thermopylæ, and all the towns of Phocis at once surrendered. Philip then proceeded to Delphi, and called an assembly of amphictyonic deputies, who decreed that all the Phocian cities except Abæ should be destroyed, and that they should repay by yearly instalments the treasures they had plundered from the temple, estimated at 10,000 talents, or about \$10,000,000. The two votes formerly held by the Phocians in the amphictyonic council were transferred to the king of Macedon; Sparta was deprived of her rights there; and Philip was to share with the Thebans and Thessalians the right of presiding at the Pythian games. These events occurred in 346. Macedon was now the leading power in Greece. Philip commenced a series of intrigues in the Peloponnesus, which Demosthenes endeavored to counteract by his personal presence, but with no result. Philip now began his preparations for an attack on the Persian empire, which he had probably long meditated, by marching against Thrace (342), and menacing the Athenian possessions

in the Chersonesus, which brought his forces into conflict with Diopithes, who, not limiting himself to the defensive, invaded the places in Thrace which had submitted to Philip. The Macedonian king complained of these proceedings, but Diopithes was defended by Demosthenes, and retained in the command. In 341 Philip continued his movements, captured Seilymbria, and attacked Perinthus, but not succeeding in taking it immediately, left a part of his army to continue the siege, and marched upon Byzantium. He addressed a letter to the Athenians, charging them with violating the peace. Demosthenes persuaded them to equip a fleet, which was unfortunately placed under the command of Chares, and the expedition was a failure. Phocion was then appointed in his place, and, sailing with 12 triremes, forced Philip to raise the siege of Byzantium and Perinthus, and to withdraw from the Chersonesus. In 339 the amphictyonic council declared war against the Amphissian Locrians, for encroachments on the sacred lands of the temple at Delphi. Cottyphus was first appointed to the command of the amphictyonic forces; but failing in the object of the appointment, the amphictyons gave the command to Philip. Early in 338 he commenced his march; but instead of proceeding directly to Amphissa, he seized Elatea, a town in Phocis, which commanded one of the principal approaches to Bæotia and Attica. This movement, when known in Athens, produced great excitement and alarm. An assembly was summoned the next morning. Acting under the advice of Demosthenes, an embassy was despatched to Thebes, of which Demosthenes himself was the leading member; they met ambassadors from Philip, who was anxious to prevent a union between the two cities. The earnest and eloquent representations of Demosthenes carried the day, and an alliance was made. The united armies of Thebes and Athens took the field, and, after gaining the advantage in two skirmishes, fought a decisive battle on the plain of Chæronea. The fortunes of the day were decided by a charge made by the young Alexander upon the Theban sacred band, which was cut to pieces. The allied army was utterly defeated—an event fatal to the independence of Greece. At Athens the greatest consternation prevailed, but vigorous measures were taken to put the city in a state of defence, and Demosthenes was appointed superintendent of the fortifications. Philip showed great moderation toward the Athenians, offering them favorable terms of peace, and dismissing their prisoners without ransom. The Thebans were more severely dealt with; the exiles were restored, the government was transferred to them, and a Macedonian garrison was placed in the Cadmea. Philip called a congress of the states at Corinth, at which war was declared against Persia, and he was made commander-in-chief. In the autumn he returned to Macedonia to

make preparations for his eastern campaign; but his departure was delayed by domestic events, and in the spring of 336 he was assassinated, after sending forward a body of troops. Alexander, then 20 years old, immediately succeeded to the throne, and announced his intention to follow in his father's footsteps; but the occasion of Philip's death was seized by the Greeks for an attempt to throw off the Macedonian supremacy. Alexander's vigor and rapidity of action disconcerted the movement. He advanced rapidly toward Thebes, and the Athenians despatched envoys to deprecate his anger. A general congress was assembled at Corinth, and Alexander was appointed to his father's place as commander-in-chief of the expedition against Persia. Returning to Macedonia, with the intention of commencing his march to the East, he was prevented from carrying his plans into immediate execution by the disturbed state of the Thracians and Triballians. He marched against them, and quickly reduced them to obedience; but his absence in the north tempted the Greeks, especially the Athenians and the Thebans, into another insurrection. Alexander suddenly appeared in the neighborhood of Thebes, defeated the insurgents, took the city, sold the inhabitants into slavery, and levelled the houses, except that of Pindar, preserving only the Cadmea for a Macedonian garrison. He demanded that the ten leading orators of Athens should be surrendered to him, and was only induced to desist from this requirement by the intercession of Phocion. Having settled the affairs of Greece, and leaving Antipater as regent, in the spring of 334 he set out on his march for the Hellespont. (See ALEXANDER THE GREAT.) In the distribution of Alexander's vast dominions among his generals on his death (323), Antipater and Craterus were to share the government of Macedonia and Greece, in the name of his half-brother Philip Arrhidaeus and of the child of Roxana, should that be a son, as associated kings, while Perdicas and Leonnatus were to act as regents in the East; arrangements which were of short duration, and were followed by numerous other partitions of power and provinces. During Alexander's absence from Greece attempts had been made to throw off the Macedonian yoke. The Spartans took up arms, but were defeated near Megalopolis by Antipater (331). In 325 Harpalus arrived in Athens with treasures he had stolen from Alexander; but though he attempted to bribe the leading politicians, he did not secure the protection of the state as he had expected. The news of Alexander's death made a great change, and the party opposed to Macedon in Athens immediately rose to the supremacy. An extensive confederacy was formed, an army was assembled near Thermopylæ under the command of Leosthenes, and Antipater, who had thrown himself into Lamia near the Mælian gulf, was closely besieged. He was reduced to such straits that he sent an embassy

to Athens to sue for peace; but the Athenians refused to listen to any terms short of unconditional surrender. Leonnatus had come from Hellespontine Phrygia with an army of 20,000 foot and 2,500 horse. Antipater, who had succeeded to the command of the allied army after the death of Leosthenes at Lamia, met him in Thessaly, defeated his army, and slew the leader. Antipater soon after joined the defeated army, and, being reinforced by Craterus with a considerable force from Asia, defeated the allied army near Crannon (322). The allies now sued for peace; but Antipater would only treat with the separate states, and all except Athens speedily laid down their arms. As Antipater marched upon Athens, Phocion was sent in the hope of securing favorable terms. Antipater required that a certain number of the orators, including Demosthenes and Hyperides, should be surrendered, that a property qualification should be required for the franchise, and that a Macedonian garrison should be received into Munychia. On the motion of Demades, the Athenians condemned the orators to death; but they escaped from Athens before the arrival of the Macedonians. They were torn from the sanctuaries in which they had taken refuge by Archias, an officer of Antipater. Demosthenes put an end to his life by taking poison in the temple of Neptune, on the island of Calauræa; Hyperides was barbarously put to death at Athens. In the East, quarrels broke out between Perdicas, who had become the principal regent, and the other generals of Alexander, who assailed him on all sides. In 321 he marched against Egypt, and was there assassinated by some of his own officers. Antipater was now declared regent, with the government of Macedonia and Greece. He died in 319, and was succeeded by Polysperchon as regent, who proclaimed the independence of the Grecian states, and despatched his son Alexander with orders to compel the Macedonian garrison to evacuate Munychia. Phocion took refuge with him, but was sent back in chains to Athens, where in 317 he was put to death with every circumstance of outrage and indignity. Polysperchon being unsuccessful in an expedition in the Peloponnesus, the Athenians joined the alliance of Cassander, Antipater's son, who established an oligarchy at Athens under the government of Demetrius Phalereus. He became master of Macedonia, and in 315 restored Thebes, which had been in ruins since its destruction by Alexander. In the same year a war broke out in the East, but in 311 a peace was concluded, which was violated the next year by Ptolemy, governor of Egypt. In 307 Antigonus, who then held almost all Asia Minor and Syria, sent his son Demetrius, afterward called Poliorcetes (besieger of cities), to Athens with a powerful fleet. Demetrius Phalereus was forced to surrender, and returned to Thebes. The ancient constitution was restored, and Demetrius and his father

were honored by the addition of two new tribes, the Demetrias and Antigonias. In 306 Demetrius, being called away from Athens, gained a great victory over Ptolemy at Salamis in Cyprus. Antigonos in Asia Minor, Seleucus in Babylonia, Ptolemy in Egypt, and Lysimachus in Thrace now assumed the title of king. Demetrius Poliorcetes again returned to Greece, while Cassander was besieging Athens. Cassander retired, and Demetrius was again received with honors. The struggle between Antigonos and his rivals was brought to a close by the battle of Ipsus in Phrygia (301), in which Antigonos was defeated and slain; after this the Athenians refused to receive Demetrius. Cassander became master of Greece; Seleucus and Lysimachus divided the kingdom of Antigonos, the former receiving the lion's share, part of Asia Minor and the whole of Syria. In 300 Demetrius ravaged the Thracian Chersonesus, and formed an alliance with Seleucus, marrying his daughter, and then made another attack upon Athens, driving out the tyrant Lachares. Soon afterward Demetrius conquered Macedonia, distracted by the rival pretensions of the sons of Cassander. He attempted to recover the Asiatic provinces of his father; but Macedonia was invaded by Pyrrhus, king of Epirus, and Lysimachus, and Demetrius was obliged to fly. He died in Syria in 283. The further wars between the successors of Alexander hardly belong to the history of Greece.—In the midst of the Macedonian domination an important movement took place in Achaia, a narrow strip of country on the northern coast of the Peloponnesus. A league, chiefly for religious purposes, had existed from ancient times among the cities of this region, and though it had been suppressed by the Macedonians, Aratus of Sicyon revived it in 251, with a political organization under a chief entitled the strategus, or general, a secretary, and a council of ten demiurgi, the sovereignty residing in a general assembly composed of citizens who had reached the age of 30, which met twice a year at Ægium. The confederacy rapidly increased in extent and power, but in 227 was involved in a war with Sparta. Aratus was then strategus. He invited assistance from Macedon, then ruled by Antigonos Doson. In 223 he compelled the Spartan king Cleomenes to withdraw to Laconia. In 221 Cleomenes was defeated by Antigonos in the battle of Sellasia. The Ætolians, who had long been united in a league of tribes, made incursions into the Peloponnesus, and coming into collision with the Achæans under Aratus, near Caphyæ, the latter were defeated. This led to an alliance between the Achæans and Philip, the young king of Macedon, in 220. After gaining several victories, he made a peace with the Ætolians in 217. The war between Rome and Carthage now attracted the attention of the Macedonian king, who in 216 concluded a treaty with Hannibal, and went so far as to meditate an invasion of Italy. While laying siege to Apol-

lonia he was attacked by the Roman consul, M. Valerius Lævinus, and compelled to retire. Having differences with Aratus with respect to some of his proceedings in Greece, he caused him to be taken off by poison in 213. In 211 the Romans made an alliance with the Ætolians, and declared war against Philip. They took several islands, which they surrendered to the Ætolians in the course of the year. In 209 the Achæans again solicited the aid of Philip. They were at this time led by Philopœmen, the "last of the Greeks," and in 208 he was elected strategus of the league. In 207 he defeated the Lacedæmonians at Mantinea; and as the Romans, having made peace with Philip in 205, retired from Greece, the country was left in a state of tranquillity for several years. In 200 they declared war against him, and a Roman fleet relieved Athens, which he was besieging; but in retiring he committed great ravages in the suburbs of the city. In 198 the Achæan league joined the Roman alliance, under the influence of the consul T. Quintius Flamininus. In 197 Philip was defeated in the battle of Cynoscephalæ, and peace was made in the following year, the Macedonians being compelled to renounce their supremacy, and to pay 1,000 talents for the expenses of the war. The Greeks assembled at the Isthmian games received the announcement of their new liberty with shouts of joy; but their dissensions continued, and soon broke out in fresh conflicts. The Ætolians having persuaded Antiochus the Great of Syria to come with an army into Greece, he was defeated at Thermopylæ in 191, and the Ætolians were obliged to ask for peace, and to submit to the most humiliating conditions. Philopœmen in the mean time had joined Sparta to the Achæan league; but that city proving intractable, he marched upon it, razed the walls, and compelled the citizens to adopt a democratic constitution. In 183 Philopœmen was taken prisoner by the Messenians, who had revolted from the league, and put to death. In 179 Philip died, and was succeeded by Perseus, who found large preparations made for a renewal of the war with the Romans. In 171 the Romans declared war against him, and the consul L. Æmilius Paulus was sent to Macedonia in 168. The war was ended by the battle of Pydna and the surrender of Perseus, who was carried to Rome to adorn the triumph of his captor. Commissioners were sent from Rome to arrange the affairs of Macedonia; but it was a quarrel between Athens and Oropus which finally gave the Romans an opportunity to bring all Greece into subjection, by destroying the Achæan league. The Oropians complained to the Roman senate; the Romans appointed the Sicyonians arbitrators, and they having condemned the Athenians to pay a fine of 500 talents, the latter sent an embassy of three philosophers, Diogenes the Stoic, Critolaus the Peripatetic, and Carneades the Academic, who succeeded in reducing the fine to 100 talents. Still fresh aggressions occurring,

the Oropians appealed to the Achaean league, which, at first declining to interfere, was finally involved by the intrigues of several leading men, among whom was Diaeus the strategus, in a quarrel with Sparta. The latter appealed to Rome, and in 147 two commissioners were sent to Greece, who decided that Sparta, Corinth, and the other cities except those of Achaia, should be independent. This decision led to acts of violence; and finally Metellus, marching into Greece, defeated Critolaus the strategus in Locris. Diaeus succeeded him; but another Roman force under Mummius landed on the isthmus of Corinth and defeated him in a battle fought near the city. Corinth was taken in 146; the city was burned; the works of art with which it was filled were transported to Rome; ten commissioners were despatched to settle the condition of Greece, and the whole country became a Roman province under the name of Achaia.—The Romans at first used their power with such moderation as to excite the admiration of Polybius, who was one of the 1,000 Achaeans sent to Italy. The religion and the municipal institutions of the Greeks were treated with respect. Their eminence in literature and the arts qualified them to be the teachers of the Romans, who sent their youth to Athens to complete their education under the instruction of the scholars and philosophers of this city, which long retained its preëminence. It was not until the Mithridatic war that the Greeks made an attempt to throw off the Roman power. The losses sustained by Greece in this unhappy period were never repaired. The Cilician pirates soon after ravaged Greece; they were destroyed by Pompey. The civil wars that overturned the Roman republic desolated Greece; but the empire at length established peace throughout the civilized world. Greece continued to be the school of letters and art. She was still crowded with temples and statues, the products of the best ages. Her schools of philosophy and rhetoric flourished; the forms of public life were maintained, and but little change was made in the municipal administrations. But the dignity and influence of official position gradually sunk in the public estimation under a foreign supremacy. Augustus established military colonies. His successors generally treated Greece with respect, and some of them distinguished her by splendid imperial favors. Trajan even greatly improved her condition by his wise and liberal administration. Hadrian and the Antonines venerated her for her past achievements, and showed their good will by the care they extended to her works of art, and their patronage of the schools. About the middle of the 3d century A. D. hordes of Goths appeared on the frontiers, and soon after covered the Hellespont and the Ægean. Athens was gallantly defended by Dexippus the historian. Among the influences that essentially modified the condition, intellectual and moral, of the people of Greece, was that of Christianity, which

was introduced by the apostles themselves, and, from the time of St. Paul's discourse on the Areopagus, had been gaining upon the ancient paganism. The *ecclesia* became the church, and the *liturgia* passed over from the public political offices of the Athenian state to the Christian service. In 330 the seat of the Roman empire was removed to Constantinople, an event which brought Greece into closer relations with the Roman administration, though the local governments were still allowed to exist. The emperor Julian attempted to check the growth of Christianity, and to restore the ancient rites, but with little success. In 395 the separation of the eastern and western empires took place; and as the Greeks naturally belonged to the eastern, they now exercised a more powerful influence on the government. About this time the name Hellenes began to be limited to the adherents of the ancient religion. In the reign of Justinian (527-565) the philosophical schools of the Greeks in which doctrines adverse to Christianity were taught were closed; but much was done for the protection of Greece from foreign invasion. The western empire fell in 476; but the eastern Roman empire continued, becoming more and more properly Byzantine. (See BYZANTINE EMPIRE.) During this period the events which exercised the most important influence upon the condition of Greece were the immigrations of the Slavs and other races, commencing early in the 6th century. In the early part of the 8th century they occupied a large part of the country, and held possession of the coasts, displacing to a considerable extent the Greek population. But in the course of time they retreated, and the country was mainly restored to the descendants of its ancient inhabitants. Yet to this day the effects of these Slavic settlements are witnessed in the physical character of the people in some districts, especially of the Peloponnesus. Numerous traces of them are detected in Slavic names of persons and places, and in Slavic words still found in the language of the common people. But the theory advanced by the German Fallmerayer, that the Greek people wholly disappeared from Greece, and that the present inhabitants are Slavs, will not stand investigation. No important change occurred from this time until the conquests by the Normans. Robert Guiscard landed in Corfu in 1081. Bohemond invaded Illyria soon after. In 1146 Roger, king of Sicily, mastered Corfu, and, marching through the mainland, plundered Corinth, Thebes, and Athens. In the fourth crusade, commencing in 1203, Constantinople was taken by the Latin princes, who also divided Greece among them. The marquis of Montferrat became sovereign of Salonica (Thessalonica); Achaia and the Morea (Peloponnesus) became a principality under Guillaume de Champlitte and Geoffroi Villehardouin; a dukedom was established in the archipelago with Naxos as its seat; but the most remarkable of

these Frankish establishments was the dukedom of Athens, existing from 1205 to 1456. All these Frankish governments were swept away by the Turks, who, having captured Constantinople in 1453, in a few years thereafter extended their conquests over Greece, and incorporated it into the Turkish empire. It was organized into pashalics, mussemlics, agalics, and vaivalics, all subject to a supreme magistrate called *Rumeli valesi*, or grand judge of Roumelia. Some of the more mountainous regions were never thoroughly subject to the Turks, but maintained a rude independence. Under the Turkish system of administration the country sunk gradually to a most miserable condition. The Greek islands, being left more to themselves, suffered less from the rapacity and barbarism of their masters. But there were several causes which tended to preserve the Greek nationality even under this foreign and most oppressive domination. The domestic institutions and the religion of the Turks were objects of such abhorrence to the Christian Greeks that no amalgamation of the two races could take place. The Greeks cherished an inextinguishable devotion to their church, the foundation of which they traced directly to the times of the apostles, while the hymns and liturgies were the work of the most eminent Christian fathers. In this state of mutual repulsion, and of barbarous oppression of the superior by the inferior race, nearly four centuries passed away, with only a few spasmodic efforts to break the yoke of the tyrant. But the Turkish sultans, almost from the beginning of their establishment at Constantinople, were obliged to employ Greeks, chiefly Fanariotes, in several important branches of the public service. (See FANARIOTES.) Greek mercantile houses were established not only in the Levant, but in the principal cities of Europe, and the eminent abilities of the race were shown by their great success in every department of commerce. In western Europe, a revival of the taste for Greek literature was brought about by the presence of learned Greeks who fled from Constantinople at the time of its capture. In the last half of the 18th century the spirit of nationality and the desire of independence received a strong impulse throughout the Hellenic race. Education was everywhere promoted; a secret society was formed, called the *Heteraria*, the object of which was the emancipation of the country. Eminent writers—Rhigas, and later Coray—appealed to the glorious recollections of Greece, and excited a universal enthusiasm for freedom. These preparations continued in the first quarter of the 19th century; and the insurrection, long looked for, broke out in 1821. The attempt of the Heterists under Alexander Ypsilanti in the Danubian principalities met with a speedy and disastrous end (June); the Suliotes of Epirus, encouraged by Ali Pasha of Janina, rose in vain; and the attempted risings in Candia (1821) and Scio (1822) were stifled in

the blood of the inhabitants. But the revolt which broke out in the Peloponnesus early in the first year was more successful; Patras, Tripolitza, and other places were taken; central Greece joined the movement; Hydra, Ipsara, Spezzia, and other islands of the archipelago furnished daring mariners; and the struggling people found heroic chiefs in Bozzaris, the Mainote bey Mavromichalis and his sons, Canaris, Miaulis, Colocotronis, Odysseus, and others, and statesmen in Mavrocordatos, Colettis, Negriss. In 1822 a provisional constitution was framed by a national assembly held at Epidaurus, and a proclamation of independence solemnly published to the world. The contest was carried on in the most barbarous manner by the Turks. The bloodshed at Constantinople, the execution of the patriarch, the massacres of Scio, excited for the Greeks the deepest sympathies, procuring for them the aid of enthusiastic Philhellenes, Byron among others. On the other hand, the Greeks here and there imitated the atrocities of their oppressors. At Missolonghi (1822-'6) and numerous other places they showed themselves worthy of their Hellenic ancestors. The battle of Navarino, Oct. 20, 1827, in which the combined squadrons of England, France, and Russia annihilated the Turco-Egyptian fleet, was the decisive event; in the following year Ibrahim Pasha was forced by Marshal Maison to evacuate the Peloponnesus, and Russia began its Turkish war under the command of Diebitsch. The sultan was compelled to come to terms. Count Capo d'Istria, a distinguished Greek statesman, then in the service of Russia, had been chosen president, arriving in Greece in the beginning of 1828. Hostilities virtually ceased the following year. The great powers now occupied themselves with the settlement of Greece. They selected Prince Leopold, afterward king of Belgium, as sovereign of the emancipated state; he at first accepted the offer, but, owing to a difference on the question of boundaries, renounced the unoccupied throne a few months afterward. In October, 1831, President Capo d'Istria was assassinated at Nauplia, and six months of anarchy followed. The great powers then fixed upon Otho, the second son of the king of Bavaria, a prince then (1832) only 17 years old. He assumed the government, under the direction of a regency, and arrived at Nauplia in 1833. The boundaries of the kingdom of Greece were determined by a treaty between the great powers and the Porte in 1832. The seat of government was first established at Nauplia; but in 1835 it was transferred to Athens, where the king, after his marriage with the princess Amalia of Oldenburg, established his court. After attaining his majority in 1835 he governed in his own name, by ministers responsible to himself, aided by a council of state. The treaty said nothing about a constitution, though the Greeks expected one, and were disappointed not to receive it immediately. The government of the

king was despotic in principle, but mild and equitable so far as depended on himself. Ten years after Otho's accession the popular dissatisfaction reached its height, and the palace was surrounded on the night of Sept. 14, 1843, by the army and the people, demanding a constitution. After some hesitation the king yielded, and a political revolution was effected without violence. A national assembly was convoked, and a constitution, the result of its labors, was laid before the king on March 4, 1844. It received his sanction on the 16th. During the ten years following its adoption, Greek politics were in a state of almost constant confusion, in which partisan contests were fostered by foreign intrigues. The history of the first decade of constitutional government in Greece is a record of little more than party struggles for supremacy, turbulent elections, ministerial changes, and insurrections, which in one or two instances attained formidable proportions. The chief feature of this period of political disturbance was the constant struggle for power between the national party and the various foreign elements, which in the peculiar position of Greece were able to control its government in a very great degree. There were frequent changes of ministry, and the material interests of the country suffered. In 1847 a diplomatic difficulty, arising from an alleged discourtesy of the Turkish ambassador at Athens, threatened to involve the government in a war with Turkey. In the next year a series of grave differences with England, arising out of demands made by her upon Greece for damages sustained by British subjects under various circumstances, threatened a far more disastrous result. The complications arising from these claims, and especially from the claim of a certain Pacifico, a Jew who was a British subject, continued for several years to disturb the relations between the two countries. In January, 1850, they had assumed so threatening an aspect that a British fleet appeared off the Piræus, and, the demands of the English ambassador not being complied with, proceeded to blockade Athens and to make many arbitrary seizures of Greek shipping. The mediation of the French was sought, but England refused it; and Greece was compelled to yield to her demands in order to avoid an actual war. In 1852 the failure of the grape crop produced much suffering among the people. In 1853 a severe earthquake caused serious loss of life and property in many parts of the kingdom. Banditti infested the Peloponnesus and central Greece, and several popular disturbances took place. At the outbreak of the Crimean war Greece took a decided stand in favor of Russia; but the threats of England and France compelled the government to pledge itself to neutrality, and Piræus was guarded by English and French fleets, which were not removed till 1857, after many protests of the Greek government. In 1859-'61 the question of the annexation of the Ionian islands, which had

long been under the protectorate of Great Britain, was the most important and exciting feature of Greek politics. The opposition manifested by the people of the islands to English rule had for several years been manifested by popular demonstrations and even insurrections; and, in the already excited state of public feeling against England, these received the encouragement and sympathy of the Greeks. But the powerlessness of Greece was too manifest to permit her undertaking a war; and the matter ended, after long diplomatic negotiation, in the continuance of the former relations. In the mean time the general hostility felt toward the German king and the royal family had increased to such a degree that open demonstrations were made against them when they appeared in public. Dossios, a student who attempted to assassinate the queen in September, 1861, was openly defended by many of the people; and threats were everywhere uttered against King Otho. An attempt at conciliation made by him in January, 1862, when he promised the adoption of a series of liberal measures, failed through his unwillingness to go as far as the popular voice demanded. After several minor insurrections elsewhere, a revolution broke out in Athens on Oct. 22, 1862. It was speedily successful through the apathy of the army in the royal cause; and on the 23d a provisional government was established by the leaders of the popular party. They immediately decreed the deposition of King Otho, and the calling of a national assembly. The king, who was absent on a voyage to the ports of the Peloponnesus, received the news of what had occurred as he reached the Piræus on his return. Without landing, he held a council with the diplomatic representatives in Athens on board his ship, and in accordance with their advice he issued a proclamation on the 24th taking leave of Greece, but without making a formal abdication; and shortly after he returned in an English frigate to Germany. On Dec. 1 a decree was issued by the provisional committee ordering the election of a new king by universal suffrage. Several candidates for the throne had been brought forward by the great powers, Prince Alfred of England and the duke of Leuchtenberg being among the chief. At the first ballot Prince Alfred was elected by an immense majority, but he was afterward withdrawn by England on account of an existing agreement that no prince of either of the three special protecting powers of Greece (France, England, and Russia) should accept the throne. At the same time England expressed, in effect, its willingness, provided a king should be elected to whom the English government could not object, to abandon its protectorate over the Ionian islands, and to give them up to Greece. The national assembly called by the provisional government met at Athens on Dec. 22, and confirmed the deposition of the Bavarian dynasty (Feb. 16, 1863). On March 30 Prince

George of Denmark was unanimously elected by the assembly, and the election was confirmed by the great powers on July 13. Considerable disturbance had meanwhile existed throughout the country; but when King George landed at the Piræus in October he found the kingdom in a condition of at least outward quiet. On Oct. 31 he took the oath to support the constitution; and soon afterward the Ionian islands were formally annexed to his dominions (treaty of Nov. 14, 1863). Greek politics continued to be marked by dissension and partisan intrigue, involving constant ministerial changes and detriment to the general welfare. In 1866 the Cretan revolution threatened to involve Greece in a conflict with Turkey on account of the assistance furnished to the Cretans by blockade runners and of the asylum given to fugitives, more than 30,000 of whom, chiefly women and children, took refuge in Greece. (See **CANDIA**.) The danger was finally averted, but the finances of Greece, owing to the defensive measures during the threatening period, were left in an embarrassed condition, and financial schemes have since formed the chief feature of Greek politics. Outside of partisan struggles, only one event has in the last five years excited attention in other countries. This was the massacre by brigands of four members of a party of English travellers, who in 1870 were captured near the plain of Marathon and carried into the mountains, while a messenger was sent to Athens to offer, on the part of the banditti, the alternative of a large ransom and amnesty for themselves, or the death of all the prisoners in their hands. The Greek government would not consent to treat with the robbers, as even the king himself does not possess that power under the constitution; and though every effort was made to rescue the Englishmen, they were put to death. The affair was mismanaged through the interference of the British ambassador, who had attempted to treat directly with the brigands, offering them money and a frigate to take them to Malta; but they rejected these offers and insisted upon amnesty. England held the Greek government responsible for the massacre, on the ground that it was bound to suppress organized brigandage in its territory, and the matter threatened to lead to hostilities. But the danger was averted by negotiation and the payment of £10,000 by the Greek government to the family of Lloyd, one of the murdered travellers, and the subject was gradually suffered to drop.—The new kingdom on its establishment embraced, of the country constituting ancient Greece, the southernmost districts of Thessaly, central Greece, and the Peloponnesus. Of the islands, the Cyclades (with the exception of one), Eubœa, and a few of the Sporades (in the wider signification) were embodied in the new kingdom; the Ionian islands remained under the protectorate of Great Britain till 1863,

when they were ceded by treaty to Greece; all the other islands remained with Turkey, and the repeated insurrections, particularly in Candia, were without result. After the incorporation of the Ionian islands, the area of the kingdom of Greece amounted to 19,353 sq. m. It is now divided into 13 nomarchies, as follows, the former Ionian islands being embraced in the three last named, with the exception of Cerigo and the adjacent islets, which have been united with the nomarchy of Argolis and Corinth:

NOMARCHIES, &c.	Square miles.	Population in 1870.
Attica and Bœotia .....	2,481	136,804
Eubœa .....	1,574	82,541
Phthiotis and Phocis .....	2,053	108,421
Acarnania and Ætolia .....	3,025	121,693
Achaia and Elis .....	1,908	149,561
Arcadia .....	2,025	131,740
Laconia .....	1,675	105,551
Messenia .....	1,226	130,417
Argolis and Corinthia .....	1,443	127,820
Cyclades .....	926	123,299
Coreyra (Corfu) .....	427	96,940
Cephalonia (Cephalonia) .....	302	77,882
Zacynthus (Zante) .....	277	44,557
Soldiers of army and navy .....	...	13,785
Sailors, not present in the country .....	...	7,183
Total .....	19,353	1,457,894

—In the mountains but little vegetation besides alpine plants grows at a height greater than 5,500 ft.; but below this line the hillsides are clothed with luxuriant forests, principally of pine and oak. Lower down the walnut and chestnut abound; and below a height of 1,500 ft. is found as great a variety of valuable trees, shrubs, and plants as is afforded by any other part of the world. All the fruits belonging to the latitude grow vigorously and produce abundantly, and if cultivated with proper skill and care would afford a valuable surplus for export. Although the soil of Greece is good, agriculture has been greatly neglected. More than half the area is productive soil, of which 20 per cent. is arable land, 1 per cent. garden land, 4 per cent. vine land, 41 per cent. meadow and pasture, and 34 per cent. wood land. The most important products are olives and currants; the latter are chiefly cultivated on the coast of the Peloponnesus and on the islands of Corfu, Zante, and Cephalonia, which from 1866 to 1870 yielded an annual average product of 170,000,000 lbs., the larger portion of which was exported to England. Wine culture yields annually about 18,000,000 gallons. Among the other products are tobacco, cotton, figs, lemons, and valonia. Breeding of sheep, goats, and silkworms is also carried on to a considerable extent; several places on the coast have extensive fisheries. The culture of forests is greatly neglected, although the country has a peculiar kind of oak which is important for commerce. The number of horses is estimated at 100,000; of mules and asses likewise at 100,000; and in 1867 there were 109,904 cattle, 2,539,538 sheep, 2,415,143 goats, and 55,776 swine. The

The names in capitals are those of the Eparchies. These form 13 larger-divisions called Nomarchies, the boundaries of which are shown by red lines.

UNIVERSITY OF ILLINOIS

most important mineral products are the marble of Paros and the emery of Naxos, the latter a government monopoly. The famous Laurian lead mines in Attica, recently reopened by a Franco-Italian company, promised so large a yield as to lead to a conflict between the government and the company, but the difficulty was settled by the purchase of the foreign interest by a Greek company. The sea-salt works yield annually about 253,000 cwt. of salt.—The commerce of Greece is considerable, owing to the favorable situation of the country. The imports and exports from 1869 to 1871 were as follows:

YEARS.	Imports.	Exports.
1869 .....	\$18,215,000	\$12,073,000
1870 .....	18,725,000	10,211,000
1871 .....	20,947,000	14,643,000

The most important articles of import were: breadstuffs, \$4,940,000; manufactures, \$3,570,000; skins, \$1,669,000; sugar, \$1,961,000; lumber, \$808,000; animals, \$530,000; cotton yarn, \$453,000; coffee, \$351,000; rice, \$324,000. The most important exports were: currants, \$5,851,000; skins, \$526,000; olive oil, \$2,063,000; raw cotton, \$221,000; figs, \$700,000; oranges, \$106,150; tobacco, \$137,030; wine, \$152,000; silk cocoons and raw silk, \$252,000; soap, \$89,000; lead, \$689,000. The merchant navy at the end of 1871 numbered 6,135 vessels, with an aggregate of 419,350 tons; among which were more than 4,000 coasting vessels, and 12 steamers, with an aggregate of about 5,360 tons. The movement of shipping in 1870 and 1871 is shown by the following table:

ENTRANCES AND CLEARANCES.	Years.	Vessels.	Tons.
Sea-going vessels .....	1870	16,757	2,564,964
Coasting vessels .....	"	94,991	2,985,520
Sea-going vessels .....	1871	21,753	3,205,619
Coasting vessels .....	"	105,612	3,960,790

The manufactures are few and unimportant. The prominent branches of industry are ship building, the manufacture of leather (chiefly on the island of Syra), silk and linen goods, sails and cordage, soap, liquors, and gold and silver embroideries. The first railway of Greece, connecting Athens with Piræus and Phalerum, and having a length of  $7\frac{1}{2}$  m., was opened in January, 1869. A road connecting the port of Piræus with Lamia, which will be 138 m. long, was begun in December, 1872; and a charter had been given for building a road from Athens to Kalamata, to be 170 m. long. In 1870 there were 992 m. of electro-magnetic telegraph, with an aggregate length of wires of 1,116 m. Submarine cables are in operation between Athens, Syra, Scio, Constantinople, and Candia. The number of post offices in 1870 was 135. The monetary unit is the new drachma, which is equal to 19·3 cents;

it is divided into 100 leptas. The standard of weight is a cantar, equal to 124·13 lbs. avoirdupois; it is divided into 44 oke, and subdivided into 400 old or 1,280 royal drams. The unit of long measure is the royal pit, equal to 1 metre or 3·2808 feet. Land is measured by the stadion, which is equal to 0·62 of an English mile.—The constitution under which Greece is now governed bears date Nov. 17, old style (Nov. 29, new style), 1864. The throne is hereditary. The king attains his majority when 18 years old. Before his accession to the throne he must take the oath to the constitution, and within two months after the accession he must convoke the legislature. The successors to the present king, who is a Lutheran, must belong to the Orthodox church. The legislative power is shared by the king with a single chamber of representatives, called the *boule*, which is elected every fourth year; in the session of 1871-'2 it consisted of 188 members. It meets annually on Nov. 1 (old style), and remains in session not less than three and not more than six months. It elects its own president and vice presidents. State officers, mayors, and military officers in active service, are not eligible; clergymen can neither be elected nor vote. The elections are by ballot with the use of balls, and each candidate must be put in nomination by the requisition of at least one thirtieth of the voters of an electoral district. The right of voting belongs to all citizens who are 21 years of age and have a property, a trade, or any fixed occupation. To be eligible as deputy, it is necessary to be 30 years of age and to own real estate. All citizens have equal rights and duties; nobility has been abolished. The executive power is exercised by the king through responsible ministers, of whom there are seven: of the interior, of finance, of justice, of education and ecclesiastical affairs, of war, of marine, and of foreign affairs. For administrative purposes, the 13 nomarchies are subdivided into 59 eparchies and 351 demoi (communes). At the head of these divisions are nomarchs, eparchs, and demarchs; the latter are, like the communal councils, elected for a term of four years. There is a court of cassation (the *arcopagus*) at Athens, four courts of appeal (at Athens, Nauplia, Patras, and Corfu), 16 courts of primary jurisdiction, the court of assizes, 175 tribunals of justices of the peace, and a number of military and marine courts. The finances of the kingdom are in a very unfavorable condition. In the budget estimates the revenue generally shows a small surplus over the expenditures; thus in the estimates for 1873 the revenue was estimated at \$6,928,000, and the expenditures at only \$6,832,000; but in reality the expenditures since 1866 have exceeded the revenue by about \$2,700,000 annually. Official returns giving the real income and expenses of the government have not been published since 1859. The funded debt amounted in July, 1870, to \$65,000,000 (in-

cluding the interest on the loans contracted in 1824 and 1825, which has not been paid, the former since July, 1826, the latter since January, 1827). The floating debt, according to semi-official returns, amounted in January, 1870, to \$6,900,000, but there is also an unrecognized debt of several millions. By the new law of recruitment of 1867, the liability to military service is universal. The armed forces consist of the army and the national guard. The duty of serving in the army begins with the 20th year, and lasts 12 years (three years in the line, three in the first, and six in the second reserve). If necessary, all Greeks capable of bearing arms, up to the age of 40, can be enlisted in the army. In the national guard, which is to be employed for the defence of the country in time of war, all citizens must serve from the 18th to the 50th year of age. The strength of the army in 1871

Modern Greek Costume.

was 12,400 men on a peace footing, and about 48,000 men in time of war, including the volunteers; the national guard numbers about 90,000 men; and the total strength of the army on a war footing would therefore be about 138,000 men. The navy at the close of 1871 consisted of 2 iron frigates, 8 screw steamers, and 11 sailing vessels, with an aggregate of 200 guns and 2,500 men. The navy is manned by conscription from the inhabitants of the seacoast; but volunteering is greatly encouraged by the government.—In the population of Greece but a small foreign element is mingled. The number of those not speaking the Greek as their native tongue amounted in 1870 to only 67,941, of whom 37,598 were Albanese (Arnauts), 1,217 Macedo-Wallachs, and 29,126 others. The immense majority of the population are connected

with the Orthodox (Greek) church; the number of other Christians, chiefly Roman Catholics, in 1870, was 12,585; of Jews, 2,582; of all others, 917. The affairs of the Orthodox church are under the direction of a permanent holy synod at Athens, consisting of five members appointed by the king from the archbishops and bishops, and presided over by the metropolitan of Athens. All their resolutions must be confirmed by the king. The Orthodox church has 15 archbishops, the first of whom is the archbishop of Athens, who has the title of metropolitan, and 16 bishops. The archbishops and bishops are presented for their office by the synod, and confirmed and appointed by the king. Exclusive of the Ionian islands, the church has about 3,200 secular priests, 1,600 monks, and 1,500 nuns. Formerly the number of convents was much greater, but in 1829 about 300 were closed and their estates appropriated for churches and schools. The Roman Catholic church has two archbishops (Naxos and Corfu) and four bishops. All religions are tolerated and have freedom of public worship. Instruction in Greece is compulsory for all children from 5 to 12 years; but the attendance at the primary schools is unsatisfactory, for in 1869 the 1,141 public and private primary schools numbered only 60,634 pupils, being 4·3 per cent. of the total population. The secondary instruction in 1870 embraced 15 gymnasia and 114 Hellenic schools (corresponding to the German *Realschulen*), with an aggregate attendance of 7,780 pupils; and 23 private institutions, with 1,589 pupils. The national university at Athens has four faculties, the theological, law, medical, and philosophical, and in 1869 was attended by 1,205 students. Of special schools, there are a polytechnic school at Athens, four theological schools of the Orthodox church, six nautical schools, one agricultural school, and one military academy at the Piræus.—For an account of Greek art, see ARCHITECTURE, PAINTING, and SCULPTURE. On the geography of Greece, see William Smith, "Dictionary of Greek and Roman Geography" (2 vols. 8vo, London and Boston, 1854-'7), and the works of Mannert, Leake, Rangabe, E. Curtius, Hettner, Blouet, W. G. Clark, Linton, Bayard Taylor, Wordsworth, Périgot, Joanne, and Mansolas. On ancient history and archaeology, see Grote, "A History of Greece" (12 vols. 8vo, London, 1846-'56; 12 vols. 12mo, New York); E. Curtius, *Griechische Geschichte* (1857-'67; English translation, London, 1868-'73); Cox, "History of Greece" (London, 1874); and besides the classical writers, the works of Goldsmith, Gillies, Thirlwall, Pococke, Gladstone, Heeren, Böckh, Manso, Droysen, Duncker, O. Müller, Hermann, Schömann, Wachsmuth, Kortüm, Mitford, Clinton, Mure, and Felton. On mediæval and modern Greece, see Brunet de Presle, *La Grèce romaine, byzantine, turque et régénérée* (Paris, 1860); Tuckerman, "The Greeks of To-day" (New York,

1873); and the works of Fallmerayer, Prokesch-Osten, Villemain, Pouqueville, Finlay, Keightley, Emerson Tennent, Rizos-Nerulos, Sutsos, Gervinus, Tricupis, and Zinkeisen.

**GREECE, Language and Literature of.** The Greek language is a branch of the Indo-European family, and was spoken, probably as early as 15 centuries before our era, by the Greeks in Europe and Asia Minor, and subsequently in lower Italy, Sicily, and numerous colonies established on the coasts of the Mediterranean and Black seas. It became afterward the reigning language of the Macedonian, Syrian, Egyptian, and Byzantine empires. Besides the dialects of modern Greece, remnants of it are found in lower Italy, at the southern extremity of Calabria. The origin of the language and the degree of its relationship to other forms of Aryan speech have not been definitely established. The ancient Greeks and Romans speak of a Pelasgic race as the common stock of both nations, but without furnishing sufficient information to place it within the reach of history. The conjectures of ancient and modern writers have linked it to nearly every great nation of antiquity, but without a satisfactory result. Alstedius in the 17th century derives the Greek from the Hebrew, and the people from Javan, the son of Japheth; Webb from the Chinese; Monbodo from Egypt, believing that the Pelasgi were Goths. Martin and Buffier assert that the Phœnician Cadmus altered the language in the north, and the Phrygian Pelops in the south. Rudbeck and Ihre derive it from the Gothic, while Jamieson holds to the reverse. Grote says that he cannot accept a hypothesis which implies that "the Hellenic language is a mere confluence of two foreign barbaric languages (Phœnician and Egyptian) with two or more internal barbaric languages, Pelasgian, Lelegian, &c.," and considers futile all inquiries in regard to the ante-Hellenic Pelasgians. George Rawlinson adopts the opinion of Niebuhr, Thirlwall, and K. O. Müller, that the relation of Greek to Pelasgian was like that of English to Anglo-Saxon. Gladstone designates the Pelasgians as pure Aryan, and the Hellenes "as Aryan with a residue or mixture of Turanian elements." Geldart considers the popular notion of the Greeks themselves, that the language of the modern Albanians is that of the ancient Pelasgians, as nearest the truth. Cuno contends, in his *Forschungen auf dem Gebiete der alten Völkerkunde* (Berlin, 1871), that the Greeks and Romans used the term Pelasgian very nearly in the same sense in which modern linguists use the term Aryan or Indo-European, and that Greek is most closely related to the Lithuanian language, because it has retained the same accentuation and several forms of words which, though found in Sanskrit, have disappeared in the other languages derived from it. The belief that Latin is a daughter of Greek, which was common for centuries both in ancient and

modern times, has been rejected by many eminent scholars. The general opinion at present is that Greek is an elder sister of Latin. E. Curtius says that out of 500 Greek verbal roots only 30 reappear exclusively in Latin. Lottner says he has discovered that Greek has fewer words in common with Latin than Latin has with German, Slavic, and Lettic. Max Müller makes the following statement in regard to the affinity of the classical tongues of the Indo-European family: "No sound scholar would ever think of deriving any Greek or Latin word from Sanskrit. . . . Sanskrit, Greek, and Latin are sisters, varieties of one and the same type. They all point to some earlier stage, when they were less different from each other than they now are, but no more."—The history of the Greek language is divided by Benfey, in his *Geschichte der Sprachwissenschaft* (Munich, 1868), into three periods. The first is the period of its literary development from the time of epic poetry to the rise of the common tongue, the *koinê* or the Hellenic of the Hellenes; the second embraces the time during which the *koinê* came to be the language of all civilized nations and educated persons, and the time during which it was gradually confined again to its original limits; the third period begins with the fall of the Byzantine empire, and its principal feature is the gradual disregard of the literary language, and the rise of the popular forms of speech which finally produced the modern Greek. History becomes acquainted with the Greek language only after it had separated into numerous dialects. The dialectic differences were mainly of form and pronunciation, and but small in stems and roots. Two main classes predominate among all the dialect forms: the Doric (*ἡ Δωρική* or *Δωρὶς*) and the Ionic (*ἡ Ἰωνική* or *Ἰάς*), which were spoken by the two principal races, of which the Doric was the largest. Another principal dialect was that spoken by the Æolians of Asia Minor, Bœotia, and Thessaly. E. Curtius, in his "History of Greece" (translated, London, 1868-73), says: "There were Greeks who spoke neither Ionic nor Doric, and these were said to speak Æolic. But the Æolic is not a dialect, like the Doric and Ionic; it commands no defined territory of language, and possesses no fixed character. The so-called Æolic Greek is rather to such an extent colored differently, according to the different regions in which it settled itself, that it is impossible to fix upon a universally prevalent type, upon a fixed law of sounds, and a system of grammatical forms comprehending all its members. Speaking generally, and leaving out of the question certain more recent formations, it included those forms which, when compared with the cognate languages of Asia, we must recognize as the most ancient. The Æolic stands nearest to the original tongue of the Greeks, to that tongue which we must regard as the common mother of the various dialects—among them, of the Græco-Italic language;

accordingly, it is easy to point out undeniable analogies between Æolic Greek and Latin." The Doric dialect was spoken chiefly in northern Greece, in the Peloponnesus, in Crete, and in the numerous Doric colonies, especially Sicily and lower Italy. It is essentially the dialect of Pindar and Theocritus. Ionic was spoken chiefly in Asia Minor and Attica, in numerous islands, and in the Ionic colonies. It was early developed by poetry, and produced three different but nearly related dialects: the old Ionic or epic dialect, preserved in the poems of Homer and Hesiod; the new Ionic, chiefly known from the history of Herodotus; and the Attic dialect, contained in the literature of Athens at the time of her glory. In the Attic dialect three less important distinctions are made, the old, the middle, and the new; or the two distinctions between the earlier and the later Attic. The old Attic differed but little from the old Ionic, as the Ionians were the original inhabitants of Attica; but through intercourse with Æolians, Dorians, and other Greek and foreign races, it adopted many non-Ionic words, and produced the middle or earlier Attic, as written by Thucydides and the tragedians. The new or later Attic is considered as beginning with Demosthenes and Æschines. Through the importance of Athens and the superiority of its literature, the Attic became the chief dialect, and, even after Athens had ceased to be the leading city, remained the language of the educated Greeks. But it soon lost its purity and excellence, and thus from the 3d century B. C. the common Greek dialect (ἡ κοινὴ διάλεκτος) was distinguished from it. The conquests of Alexander gave it an enormous territory; but being spoken by Macedonians, Egyptians, Ethiopians, Syrians, and other minor nations, it was stripped of many of its original forms, and numerous barbarisms were added to it. The researches of Curtius tend to show that the Greeks and Macedonians could not understand each other. How far the Macedonian language resembled that of the Illyrians is not positively known. It is apparent, however, that at this time took place a gradual mingling of Greek and Macedonian speech, as Plutarch asserts that Greek and not Macedonian was spoken at the courts of Philip and Alexander. The fusion of the two languages produced the so-called Macedonian dialects, of which the most prominent, being cultivated by learned men, was that of Alexandria. It has been falsely termed the Hellenistic language; with its Syrian, Hebrew, and Chaldean peculiarities, it was used in the Alexandrian translations of the Old Testament, and subsequently also of the New, whence it has been carried into the works of the fathers of the church; and it has therefore been proposed to designate it as ecclesiastic Greek. The Greek spoken in Egypt was mainly a language studied by officials and traders. The dialect has been found inscribed on the stones of Rosetta and of Adule, and on a num-

ber of papyri. The Greek of Ethiopia was still more corrupt, and was also principally used in business and for inscriptions. Greek was spoken in Carthage and Mauritania, as well as in Bactria and India. It continued also to be spoken in Gallia Narbonensis and Aquitania, where, starting with the colony of Massilia established by the Phocæans in the 6th century B. C., it had gradually gained territory and become the general language of the institutions of learning. Henry Stephens shows, in his *Traité de la conformité du langage françois avec le grec* (Paris, 1569), that it remained there in use for many centuries after the introduction of Christianity. In Sicily, and in parts of Calabria and Apulia, Greek was spoken as late as the 11th century of our era. Mommsen has shown, in his *Unteritalische Dialekte* (Leipsic, 1850), that it continued to be used by the side of Latin and Arabic, until Italian usurped its place as the literary language of the country. Greek was thus during the first three centuries of our era a sort of universal language, and everybody who claimed to be educated was obliged to be conversant with it. But the language deviated perceptibly from the old standard, and the efforts of the purists to check this tendency, by insisting on using ancient Attic forms, had but little success. The transfer of the seat of government of the Roman empire to Constantinople caused the introduction of many Latinisms, and the crusades that of many Gallicisms and other foreign elements. According to Hallam, artificial Attic Greek was spoken in Constantinople, even till its capture by Mohammed II., by the superior ranks of both sexes, with tolerable purity, and at that time had degenerated only among the common people and the inhabitants of the provinces. But the literary documents show a gradual transition from the language of the grammarians to that of the people, which is designated in them as the common and impure language, or the common and simple style, and also as usage. The popular dialect of the 12th century was essentially the same as the Romaic or modern Greek of the present day, and the first writer who can be said to have used it in its entirety was Theodorus Prodromus, nicknamed Ptochoprodromus, a monk who lived in the reign of the emperor Manuel Comnenus. The appellation of Romaic, by which the new dialect was designated, arose from the circumstance that the Greeks had affected the name of Ῥωμαῖοι, after the new name of the seat of government (νέα Ῥώμη), and in distinction from the Ἕλληνες, who were the latest advocates of the language and customs of ancient Greece. But the modern theory of a complete extirpation of the Hellenic race at this present time is unsupported by the unalloyed speech of the inhabitants of modern Greece. Deffner and other students of modern Greek have shown that it contains formations evidently older than the Attic dialect, with which a large class of modern Greek

authors are now striving to supplant it. In fact, the so-called ancient forms never died out, but are nearly all found even in the more cultivated modern Greek of the middle ages. Greek is now, says Geldart, "as really alive as it was in the days of Homer." "Comparative philology derives no unimportant light from modern Greek, because it preserves many archaic forms which are postulated by philologists, but not actually to be found in any known dialect." Mullach, in his *Grammatik der griechischen Vulgärsprache* (Berlin, 1856), divides the existing dialects of modern Greece into six main varieties, besides Tzackonian and Albanian, whose claim to be considered Greek dialects is not admitted by all. They are: 1, the dialect of Anatolia (Asia Minor); 2, Chiotic; 3, Cretan; 4, Cyprian; 5, Peloponnesian; 6, of the Ionian islands. The Tzackonian dialect is the language of ancient Cynuria, and of a foreign race, which was probably of Semitic origin. It adopted and adapted the materials of the Greek language gradually, partly during the time that Greek was still ancient Greek, and partly after it had become modern. Albanian is considered by many authorities the direct descendant of ancient Pelasgic or Græco-Italic, the parent of both Latin and Greek. The modern Greek dialects of lower Italy are not well known; they are spoken in 12 villages at the southern extremity of modern Calabria.—The Greek alphabet was formed from the Phœnician. Ancient writers supposed that it was at first composed of 16 letters only, obtained from Cadmus, and that the other letters were due to Palamedes and others. Many authorities consider these personages mythical; others, like Lenormant in *La légende de Cadmus* (Paris, 1867), consider them historical. Mommsen believes that an Æolic-Achæic alphabet was in use in the Peloponnesus long before the dominion of the Dorians, who introduced their own graphic system; but his theory is hardly supported by palæographic material. Curtius's hypothesis is that the Asiatic Ionians obtained it from the Phœnicians, and carried it into European Greece about 14 centuries B. C., while Duncker argues that it was brought from Crete to Greece during the 8th century. Without regard to the period and manner in which the Greeks came into its possession, the prevailing opinion is that they adopted at once the whole Phœnician alphabet of 22 letters, and added the sign  $\Upsilon$ . Some of the letters passed out of use, as the *vau* or digamma and the *koppa*, and were replaced by others, as the *phi* and *chi*, which appear already in the old Attic alphabet. The Ionians added the *psi* and the *omega*, and employed the aspirate *eta* to designate the sound of long E. Their alphabet, thus consisting of 24 letters, was officially adopted in Athens in 403 or 401 B. C., and has since continued in general use. The ancients believed that all words beginning with a vowel had some aspiration, either soft (*πνεῦμα ψιόν, spiritus lenis*)

or hard (*πνεῦμα δασύ, spiritus asper*). The *spiritus lenis* (') is not rendered in other tongues; the *spiritus asper* (') is given in Italic and Germanic languages by H. In diphthongs the breathing stands over the second vowel. The two breathings were distinguished only during the flourishing period of Greek, and only in Doric and Attic. After Alexander the Great it seems that the *spiritus asper* lost its force in the whole language. In modern Greek both breathings are written, but neither is pronounced. The signs - and ~ over a vowel to denote that it is long or short are used only with the vowels *a, e, v*, since *ε, η, ο, ω* are distinguished by their form. The sign (') for the *spiritus lenis* is also used as an apostrophe, and further as a *coronis* over the junction of two words contracted into one. The Greeks indicate also the tone or accent of words. The circumflex accent is placed only on the last syllable, or last but one, of a polysyllabic word; the acute equally on short and on long syllables; and the grave accent may be considered to rest on every syllable not otherwise marked, especially on the final syllable of polysyllabic words, but is written as a substitute for the acute on final syllables of words within a sentence and not immediately followed by a pause. Accentuation, however, is not uniform in all Greek dialects. It is supposed by many that Aristophanes of Byzantium was the inventor of the signs of aspiration and accentuation, and that they were introduced about 200 B. C. for the purpose of teaching the language to foreigners. They do not appear in very old inscriptions and manuscripts, but there is reason to think that they were used long before his time. The ancients wrote only in uncials and capitals or majuscules. A sort of cursive or business hand made its first appearance in Alexandria about the 2d century B. C.; but the small characters or minuscules are not found in manuscripts older than the 8th century A. D.—The pronunciation of Greek in the times of Homer, Sophocles, and Xenophon is still a matter of discussion. While it has gradually become quite uniform in continental Europe, the English allowed the continuance of the English vowel sounds, a practice which had its origin with the grammar schools and crept into the universities. Many prefer the system of pronunciation called *etacism*, which was introduced by Erasmus in the beginning of the 16th century. Until then it was allowable to read ancient Greek after the pronunciation of modern Greek as spoken by the natives who fled to the west of Europe. This pronunciation is called *iotaism*, or *Reuchlinism*, after Reuchlin, who was its advocate in the time of Erasmus. It consists in pronouncing *ι, η, v, ε, ο, v* with the same sound, that of the Italian *i*; when accented, like the English *ee* in *bee*; when unaccented, like *i* in *bit*. Furthermore, *α* is pronounced like the Italian *e*, *av* like *av* or *af*, *ε* like *ev* or *ef*, *η* like *iv* or *if*; the *iota* subscript has no effect on the pro-

nunciation of the vowel above it;  $\beta$  is pronounced like our  $v$ ;  $\gamma$  before  $\epsilon$ ,  $\iota$ , &c., like  $y$ ;  $\delta$  like the soft  $th$  or the soft Spanish  $d$ ;  $\zeta$  like  $z$ ;  $\chi$  as a strong aspirate, like  $x$  or  $j$  in Spanish;  $\tau$  after  $\nu$  sounds like  $d$ ; and  $\pi$  after  $\mu$  like  $\beta$ . The Erasmians maintain that among the ancients each vowel and diphthong had its own proper sound:  $\alpha$  like the Italian  $a$ ,  $\iota$  like the Italian  $i$ ,  $\upsilon$  like the French  $u$  or German  $ü$ ,  $\epsilon$  and  $\eta$  like the Italian long and short  $e$  respectively, and diphthongs the sounds which result from the combined sounds of their component letters. They maintain also that  $\beta$  has the sound of our  $b$ ,  $\gamma$  of our hard  $g$ ,  $\delta$  of  $d$ ,  $\zeta$  of  $dz$ , and  $\chi$  of German  $ch$ ; that  $\tau$  and  $\pi$  should always retain the sound of  $t$  and  $p$ ; and that the initial aspirate should be sounded as  $h$ . The controversy has been carried on with renewed energy in recent times, but so far to no definite settlement, the etacists and the iotacists being equally supported by high authorities.—Greek grammar has received a scientific method through the results of comparative philology, especially subsequent to the labors of Bopp and Pott, and through the recent researches of Curtius. The noun in ancient Greek has three numbers, singular, dual, and plural. The dual is a later formation, and did not occur in Æolic. The distinction of the three genders, though unknown to Indo-European in its radical stage, was introduced very early, probably before the first separation occurred. There were originally only the three cases, vocative, accusative, and nominative; the genitive and dative were introduced subsequently. The three modes of declension vary in the ancient dialects. Adjectives have either three or two endings, and in the latter case the masculine and feminine agree. Personal pronouns are declined in a peculiar manner; otherwise the declensions of nouns apply also to adjectives, and with variations to pronouns and numerals. Adjectives admit of comparison. Verbs are of three genera, possessing, besides the active and passive, a middle voice; most tenses of the passive and middle voices coincide; the middle has a kind of reflexive, reciprocal, or deponent character. The tenses are the present, imperfect, perfect, pluperfect, aorist, future, and future perfect; the moods are the indicative, subjunctive, optative, imperative, and infinitive. The preterite tenses are formed by augment and reduplication. There are active, reflexive, and passive participles, and verbal adjectives. The endings are inflected according to the character of the verbs, which terminate either in  $\mu$  or in  $\omega$  in the first person singular of the present indicative.—The language of the common people of modern Greece has a number of striking peculiarities.  $\delta\acute{o}\xi\alpha$  and words like it make in the genitive  $\tau\eta\varsigma \delta\acute{o}\xi\alpha\varsigma$ , in the plural  $\eta \delta\acute{o}\xi\alpha\iota\varsigma$ , accusative  $\tau\alpha\iota\varsigma \delta\acute{o}\xi\alpha\iota\varsigma$ . A large number of nouns belonging to different declensions are made to follow one. The  $\nu$  for the accusative is dropped in pronunciation where the phonetic laws of the language admit of it. The

plural of many words, especially those of foreign origin, is formed by adding  $\delta\epsilon\varsigma$  to the stem, as  $\pi\alpha\sigma\acute{\alpha}\delta\epsilon\varsigma$ , from  $\pi\alpha\sigma\acute{\alpha}\varsigma$ , pashas. Many feminines whose root vowel is  $\omega$  or  $ou$  take  $\varsigma$  in the genitive singular, as  $\tau\eta\varsigma \mu\alpha\iota\mu\acute{o}\iota\varsigma$ , from  $\eta \mu\alpha\iota\mu\acute{o}\nu$ , monkey. Metaplastic nouns or secondary formations are common, as  $\delta \text{ πατέρας}$ ,  $\delta \text{ βασιλέας}$ . Of the pronouns,  $\epsilon\mu\acute{\epsilon}$  often appears as  $\epsilon\mu\acute{\epsilon}\nu\alpha$ , and  $\sigma\epsilon$  as  $\epsilon\sigma\acute{\epsilon}$  and  $\epsilon\sigma\acute{\epsilon}\nu\alpha$ ;  $\eta\mu\epsilon\iota\varsigma$  becomes often  $\epsilon\upsilon\epsilon\iota\varsigma$ , and in the accusative both  $\epsilon\mu\acute{\alpha}\varsigma$  and  $\mu\acute{\alpha}\varsigma$ ; and  $\imath\mu\epsilon\iota\varsigma$  becomes  $\sigma\epsilon\iota\varsigma$  and  $\epsilon\sigma\epsilon\iota\varsigma$ . The article as enclitic and proclitic is used for the personal pronoun in oblique cases. In the verbs,  $\lambda\acute{\epsilon}\gamma\omicron\upsilon\sigma\alpha\iota$  becomes  $\lambda\acute{\epsilon}\gamma\omicron\upsilon\sigma\iota$  or  $\lambda\acute{\epsilon}\gamma\omicron\upsilon\sigma\iota\sigma\iota$ ;  $\epsilon\lambda\acute{\epsilon}\gamma\omicron\upsilon$ ,  $\epsilon\lambda\acute{\epsilon}\gamma\alpha\varsigma$ ,  $\epsilon\lambda\acute{\epsilon}\gamma\epsilon\varsigma$ ; and for  $\epsilon\lambda\acute{\epsilon}\gamma\alpha\tau\epsilon$ ,  $\epsilon\lambda\acute{\epsilon}\gamma\epsilon\tau\epsilon$ . In the passive,  $\lambda\acute{\epsilon}\gamma\eta$  or  $\lambda\acute{\epsilon}\gamma\epsilon\iota$  becomes  $\lambda\acute{\epsilon}\gamma\epsilon\sigma\alpha\iota$ ;  $\lambda\epsilon\gamma\acute{o}\mu\epsilon\theta\alpha$ ,  $\lambda\epsilon\gamma\acute{o}\mu\epsilon\sigma\tau\epsilon$ , and many other forms down to  $\lambda\epsilon\gamma\acute{o}\mu\epsilon\theta\alpha$ . The verb  $\epsilon\iota\mu\acute{\iota}$  is conjugated almost like a verb in the middle voice, thus:  $\epsilon\iota\mu\alpha\iota$ ,  $\epsilon\iota\sigma\alpha\iota$ ,  $\epsilon\iota\upsilon\epsilon$ ,  $\epsilon\iota\mu\epsilon\theta\alpha$ ,  $\epsilon\iota\sigma\theta\epsilon$ ,  $\epsilon\iota\upsilon\epsilon$ ; imperfect,  $\eta\mu\omicron\upsilon$ ,  $\eta\sigma\omicron$ ,  $\eta\tau\omicron$ ,  $\eta\mu\epsilon\theta\alpha$ ,  $\eta\sigma\theta\epsilon$ ,  $\eta\tau\omicron\upsilon$ ; infinitive,  $\epsilon\iota\sigma\theta\alpha\iota$ ; and imperative,  $\epsilon\sigma\omicron$ . The termination  $\mu\iota$  is not found in the language of the common people. Modern Greek has also lost the old simplicity of expression, as may be seen by comparing a sentence from Plutarch's "Life of Cæsar" with Rangabe's translation: Original—'Ἀλλὰ Κουρίων τε λέγεται τῇ τηβέννῳ περιβαλὼν ὑπεξαγαγεῖν, αὐτὸς τε ὁ Κικέρων, ὥς οἱ νεανίσκοι προσέβλεψαν, ἀνανεῦσαι, φοβηθεὶς τὸν δῆμον, ἢ τὸν φόνον ὧς ἀδικον καὶ παράνομον ᾔχοιμενος. Translation—'Ἀλλὰ λέγεται ὅτι ὁ Κουρίων περικαλὴν φασ τότε αὐτὸν διὰ τῆς τηβέννου του, τὸν ἐξήγαγε καὶ ὁ Κικέρων, ὅταν οἱ νέοι προσέβλεψαν εἰς αὐτὸν, ὅτι ἐνεύσεν ἀποφατικῶς, φοβηθεὶς τὸν δῆμον, ἢ τὸν φόνον ὧς ἀδικον καὶ παράνομον θεωρῶν. The words are still the same that Plutarch or even Thucydides might have employed.—The grammatical and lexicographical study of Greek was begun by the sophists, especially Protagoras, by Plato, and by Aristotle in regard to rhetoric. After the decline of Grecian liberty and language many words and phrases became obsolete, and were explained by the grammarians under the titles of  $\lambda\acute{\epsilon}\xi\epsilon\iota\varsigma$  and  $\gamma\lambda\acute{\omega}\sigma\sigma\alpha\iota$ . There were  $\gamma\lambda\acute{\omega}\sigma\sigma\alpha\iota$  *ιατρικαί*, *νομικαί*, *ρητορικαί*, *φιλοσοφικαί*, *θεολογικαί*, and  $\gamma\lambda\acute{\omega}\sigma\sigma\alpha\iota$  *βαρβαρικαί*, *σκυθικαί*, *Περσικαί*, &c. Homeric lexicons appeared at an early age; one of them was Apollonius's *Δέξεις Ὀμηρικαί*, in which the youth of republican Athens searched for elucidations of the poet. Didymus compiled a "Tragic Lexicon," Theo a "Comic Lexicon," and Phrynichus a kind of dictionary, containing the more recondite and exquisite phrases of the Attic writers, and entitled *Προπαρασκευὴ Σοφιστική*. Pausanias of Cæsarea seems to have written the best rhetorical lexicon, containing illustrations of the Greek orators, as it is often quoted by Eustathius. The first who reduced into one vocabulary the Homeric, dramatic, and rhetorical lexicons was Diogenianus, a celebrated grammarian, who lived in the time of Hadrian. The most prominent writers on grammar were Aristophanes Byzantinus (about 260 B. C.), Aristarchus of Samothrace (about

150), and Dionysius Thrax (about 80), who prepared the first systematic grammar, which remained for many centuries of great value, subsequent grammars being little else than commentaries on it. Photius, patriarch of Constantinople, was the author of a celebrated lexicon, which he entitled *Λεξέων Συναγωγή*. But the most important of all the ancient lexicons is that of Hesychius, a grammarian of uncertain age, who seems to have compiled it from a vast number of sources. The dictionary of Suidas, a Christian monk who lived about the 11th century, differs from the other ancient lexicons, as it contains biographical notices of celebrated authors, and large extracts from their works. In western Europe but few were acquainted with the Greek language previous to the emigration of the Greeks to Italy in the 14th and 15th centuries. The early Greek scholars were Bede, Alcuin, John Scotus Eriugena, Humbert, Abélard, John Basing, Robert Grosseteste, Roger Bacon, and a few others. It is difficult to determine to what extent they were acquainted with the language, but in all probability their knowledge of it was insignificant. In 1476 the Greek grammar of Constantine Lascaris was published at Milan; it was the first attempt at printing from Greek types; in the printed editions of Greek classics of an earlier date Greek words were inserted with a pen. The first Greek and Latin dictionary was compiled by a Carmelite friar of Piacenza named Joannes Crastonus. It was a bare vocabulary, but was frequently reprinted with continual additions, "till at length," says Henry Stephens, "unlearned printers contending who should put forth the biggest lexicon, and offering rewards to those who would furnish the greatest number of words, the explanations, which were in the first instance so meagre, became as fat as a Boeotian sow." (See DICTIONARY.) Greek learning dawned in England toward the close of the 15th century. Milling, Selling, Latimer, More, Colet, Grocyn, and Linacre were known as students of Greek before Erasmus came to teach it at Cambridge in 1510. Later appear the names of Lilly, Lupsett, Lister, Pace, Lee, Tunstall, Stokesley, Clement, Brian, Wakefield, Bullock, Croke, Tyndale, Smith, Redman, and Cheke as Greek scholars. In France were Lefèvre d'Étaples (Faber Stapulensis), who was able to criticise the Greek of Erasmus, and Budé (Budæus), who was beyond question the most profound Greek scholar in Europe. Germany produced Reuchlin and his younger contemporary Melanchthon, who even in his youth was deemed the peer of Erasmus; and next to them Beatus Rhenanus, Luscinius, Wilibald Pirckheimer, Camerarius, Grynæus, and Hessius. In Italy Greek was in a measure superseded by the study of Latin. Vettori enjoyed the highest reputation as a student of Greek, and next to him Bonamico, Nizzoli, Parrasio, Corrado, and Maffei. The study seems to have been

little prosecuted in Spain. The Greek grammars of this period were by Clenardus (Louvain, 1530), and by Varenius of Mechlin (Louvain, 1532), both of which were often reprinted, and the former is still the basis of several modern works, such as the Eton Greek grammar. The year 1572 became an epoch in Greek learning by the publication of Stephens's *Thesaurus*. Subsequently Greek became better known, and the greatest authorities upon it were Scaliger, Casaubon, Canter, and Sylburgius. But Greek learning declined in the 17th century. Hallam says: "The decline was progressive; few scholars remained after 1620, and a long blank ensued, until Fabricius and Kuster restored the study of Greek near the end of the century. Even in France and Holland, where many were abundantly learned, and some accomplished philologists, the Greek language seems to have been either less regarded, or at least less promoted, by eminent scholars, than in the preceding century." During the 17th and 18th centuries the progress of Greek learning was mainly due to the labors of Bentley, Stanley, Pearson, Price, Hudson, Potter, Baxter, Burney, Boyle, Viger, Fischer, Labbe, Scot, Erasmus Schmidt, Fronton du Duc, Gruter, Heyne, Heinsius, Matthiæ, and Hermann. Buttmann's *Ausführliche griechische Sprachlehre*, in the revised edition of 1819, must be considered the first grammar that can lay claim to scientific method and completeness. Thiersch carefully investigated the most ancient phases of the language, and Passow's lexicographical labors have the special merit of having been made on a sound historical basis. Lobeck carefully revised Buttmann's grammar and rendered it available to modern students. Rost, Kühner, Krüger, and Mehlhorn introduced into their grammars the results of comparative philology. Later Greek grammars and lexicons are principally due to the labors of Germans, other nations having contented themselves with translating and rearranging them for the educational purposes of their own country. In fact, the contributions made in Germany toward Greek philology during the last 50 years are enormous. Every small division of the study has been specially represented by numerous publications. The principal authorities on the alphabet alone are Bäumlein and Kirchhoff; on pronunciation, Seyffarth, Liskovius, Gotthold, and Ellissen; on the digamma, Sachs, Peters, Savelsberg, and Leskien; on the hiatus, Benseler; on quantity, Spitzner and Passow; on accentuation, Götting, Geppert, and Winckler; on word building, Hempel, Budenz, Rödiger, Clemm, E. Curtius, and G. Curtius; on inflection, Koch, Reimnitz, Grotefend, Kolbe, Lissner, Ahrens, H. Müller, Aken, Francke, Döderlein, Becker, Sander, and Traut; on syntax, Bernhardt, R. Kühner, Schmidt, Fritsch, Weber, Ebhardt, Geist; on dialects in general, Ahrens; on Æolic, Giese and Hirzel; on Attic, Krasper and Dietfurt; on Bucolic, Mühlmann; on

Cretan, Bergmann; on Cyprie, Schmidt; on Epic, Gräfenhan, Lucas, and Berger; on Ionic, Lobeck. The best lexicons are by Rost and Palm, Kreussler, Keil, Peter, Schneider, Pape, Ramshorn, Jacobitz and Seiler, Benseler, and Lucas. Lexicons for the writings of single authors or groups of authors are: for Æschylus, by Wellauer; for Euripides, by Beck; for Herodotus, by Schweighäuser; for the Homeric writings, by Döderlein; for Hyperides, by Westermann; for Plato, by Ast; for Sophocles, by Schneider and Ellendt; and for the tragedians, by Fähsé. English scholars of Greek lexicography and grammar are: Green, Lightfoot, Evelyn Abbott, J. B. Mayor, A. A. Vansittart, Kennedy, R. Ellis, E. B. Cowell, Henry Jackson, W. M. Leake, Chandler, Simcox, Wordsworth, Peile, Donaldson, Liddell, Trench, Scott, Yonge, Ferrar, and others. American writers on the Greek language are: Pickering, Anthon, Crosby, Spencer, Hadley, Goodwin, Kendrick, Sophocles, Drisler, and Felton.—LITERATURE. In its widest extent, the history of Greek literature is coeval with that of the language. It begins in a period of indefinite antiquity, and comes down to the present day. If we commence with the earliest monuments, we trace it back to nearly 1000 B. C., where we find the art of poetical composition existing already in the highest perfection, in the form of epic narrative. The admirable structure and the wonderful language of the Homeric poems imply a long period of antecedent culture, striking intimations of which are found in the poems themselves. Poetry preceded prose, in the form of hymns to the gods, and songs or ballads in celebration of martial deeds. Of the earliest temple poetry no specimens have been preserved, but the Homeric hymns may give us some idea of their style. Of the earliest ballads also, none have come down to us; but the song of Demodocus in the *Odyssey* no doubt very fairly represents their primitive style of composition. The ballads were essentially epic, and led in the course of time to the proper epic, which is found in its perfect type in the *Iliad* and the *Odyssey*. The temple poetry appears to have originated in the north of Greece, and in the temples of Dodona, Delphi, and other primeval seats of Greek religious culture. Ballad poetry probably appeared very early on the Greek mainland; but its full development took place among the Ionian colonies of Asia Minor and the Ægean islands. The principal names of the legendary minstrels were Amphion, Orpheus, Thamyris, Eumolpus, Musæus, Linus, Olen, and Olympus. The earliest literary documents are the poems known as the *Iliad* and the *Odyssey*, founded on the legends of the war of Troy and the return of Ulysses; but nothing positive is known of the poet, nor where and when they were composed. (See HOMER.) About 50 compositions of various length, in a style closely resembling that of the *Iliad* and *Odyssey*, together with a burlesque poem called *Batrachomyomachia*, or the "Bat-

tle of the Frogs and Mice," have also been attributed to Homer. The epic style was continued by a series of poets called the "cyclic," of whose works only the titles, brief abstracts, and fragments have been preserved. The next development of poetry was in Bœotia, in the works of Hesiod, who also employed the epic style. His principal poems are the "Works and Days," and the *Theogonia*. The next form of Greek poetry was the elegiac, and, in close connection with it, the iambic. The rhythm of the epic poetry was dactylic, and the metre hexameter. The Ionians of Asia Minor were also the originators of the elegiac and iambic. The elegiac rhythm was also dactylic, and its measure alternately hexameter and pentameter; or rather, every alternate verse consisted of two catalectic trimeters. The principal poets in this style were (between 700 and 600 B. C.) Archilochus, Callinus, Simonides of Amorgos, who shares with Archilochus the credit of having invented the iambic trimeter, Tyrtaeus, author of the martial elegies, Mimnermus, and Solon. This species of composition is sometimes ranked with the lyric; but it is more properly to be considered as a transition from the epic to the proper lyric. The principal orders of lyric poetry were pæans, hypochæmas, parœnia, scolia, embateria, and epinicia. The forms of composition were strophic, *i. e.*, with divisions called strophes, corresponding to each other line for line; and choral, with strophes corresponding by pairs, or with these and proodes, mesodes, and epodes. The rhythms were of the richest variety, and artfully constructed so as to express by their movement the sentiment or passion intended to be conveyed by the language. The strophic composition was usually delivered with a simple musical accompaniment; the choral, with a musical accompaniment and a rhythmical motion, sometimes a dance performed by the trained *choreutæ*, or members of the band who delivered it. Of the lyric style, there were two principal schools, the Æolic and the Doric. The Æolic flourished chiefly among the Æolian colonies of Asia Minor, and especially in Lesbos. The Doric was more generally diffused over Greece, Asia Minor, Sicily, and even Italy. The principal writers of the Æolian poetry, which was strophic in form, were Alcæus (about 600) and Sappho, his contemporary, both Lesbians. Akin to this school may be considered the lyric poetry of Anacreon (about 500); not the odes which pass under his name, but the fragments which alone represent his genuine compositions, and which are rather Ionic than Æolic in tone and style. Of the poets who form, as it were, a transition to the proper Dorian choral poets, Alcman and Stesichorus may be placed at the head. Stesichorus (600) was the first to introduce the epode, and to give a greater variety to the rhythm of the strophes than had been customary. His language was the old epic, modified by some Dorian forms. Simonides of Ceos flourished about 500; Iby-

cus about 540; Bacchylides was the nephew of Simonides. We come now to the greatest master of the Dorian lyric style, and perhaps the greatest lyric poet of all ages, Pindar, born at Cynoscephalæ in Bœotia about 522. Of his numerous compositions, we have only the four series of epinician odes, *i. e.*, odes written in commemoration of victories gained at the four national festivals, the Olympic, Pythian, Nemean, and Isthmian. These are the most important specimens that have come down to us from the lyrical age. We say the lyrical age, because lyrical composition was the characteristic style during this period, although it continued to be cultivated with other species in the subsequent times.—The earliest writers of prose were those who first engaged in philosophical speculations. Of their writings only a few fragments have been preserved. Thales was the founder of the Ionic philosophy, to which belonged Pherecydes, Anaximander, Anaximenes, Anaxagoras, &c. Pythagoras established the Italian school, and was followed by Alcmaeon, Timæus, Epicharmus, Theages, Archytas, and others. In history the Ionians took the lead. Cadmus of Miletus, about 540, is the earliest; Acesilaus of Argos soon followed. Hecataeus of Miletus came somewhat later; Pherecydes of Leros, Charon of Lampsacus, Hellanicus of Mitylene, Dionysius of Miletus, all preceded Herodotus, but were rather chroniclers than historians in the proper sense of the word. The first great historian was Herodotus of Halicarnassus (born in 484), who, though a Dorian by birth, wrote in the Ionic dialect. His delightful work is preserved, and its extraordinary merits have given him justly the name of the "father of history." Literature was cultivated later in Athens than in the Asiatic colonies; but the foundations were more deeply laid, and that famous city must always be regarded as the teacher of the world in arts and letters. We have already mentioned Solon among the elegiac poets. The Athenians were of Ionian descent, and their literature may be regarded as the continuation and perfection of the literature of that race. But the characteristic form of Athenian poetry was the dramatic. During the long period of democratic Athens, especially in the time of Pisistratus, much was done for the patronage of literature and literary men. The Homeric poems were carefully revised, and the regular reading of them was one of the public entertainments of the Panathenaic festival. Dramatic poetry, in a partially developed form, had already existed elsewhere; the dithyrambic tragedy had made its appearance. The dramatic element in the Homeric epics, especially the *Iliad*, could not fail to strike the listeners at the festivals, and to suggest the idea of representing instead of narrating events; of exhibiting persons in action rather than describing them. The dramatic pageantry of the Dionysiac worship furnished another suggestion of the dramatic form. The actual starting

point of the Greek drama was the choral song, tragedy springing from the dithyramb and comedy from the phallic representation. But the direction given to the new style was determined by the several influences we have mentioned. Thespis took the first step (535), by adding action to the chorus. He was followed by Phrynichus, who was the first to bring female characters upon the stage; his "Capture of Miletus" was performed in 498. Chœrilus was his contemporary and rival. Pratinas of Phlius lived in the same period. Æschylus, the perfecter of tragic art, was born at Eleusis in 525. This great poet added a second actor, and lived to see the tragic art raised to its highest point of excellence by his own genius and that of Sophocles, who added a third. Greek tragedy is well represented by the remaining works of Æschylus, Sophocles (born in 495), and Euripides (480). Of each of the two former only seven plays are in existence; of the last there are 19, *viz.*: 17 tragedies, one tragi-comedy, and one satyric drama. It was the practice of the tragic writers to combine in one representation three tragedies, and a kind of farce, called a satyric drama, because the chorus consisted of satyrs. But instead of a satyric drama, the *Alcestis* of Euripides shows that sometimes the representation was closed by a piece resembling the modern tragi-comedy. The three tragedies were called a trilogy, and the four pieces together a tetralogy. Of the tragic poets who succeeded the three great masters, or were their contemporaries, only the titles of plays and brief fragments remain. Comedy went along with tragedy, and sustained very peculiar relations to it. It originated probably among the Dorians, and was brought into regular form by Epicharmus about 500 B. C., and he is therefore justly called the inventor of comedy. Of the proper Attic comedy Chionides and Magnes were among the earliest writers; but of their works only a few titles remain. Cratinus first exhibited about 450; 38 titles of his comedies have been collected. Crates wrote about the same year, and Phrynichus the comic poet lived a little before the Peloponnesian war; the names of 10 of his comedies are extant. Eupolis exhibited for the first time in 429; he was a contemporary and rival of Aristophanes. Of the 54 comedies which Aristophanes wrote (according to Suidas), only 11 have come down to us. His first recorded exhibition was in 427, and his last in 388. From these plays, 10 of which belong to the old comedy, *i. e.*, to that period of Attic comedy in which public and private characters were introduced by name, we can form a distinct idea of the character and tendencies of this branch of the Attic drama. There were many other writers of the old comedy, but only their names and a few fragments have been preserved. The middle comedy is that form which comedy assumed when it was forbidden by law to introduce living persons by name. Thirty-four poets belonging

to this branch are mentioned, but none of their works, of which an immense number were known to the ancients, have been preserved, except in unimportant fragments. The names of three sons of Aristophanes occur in this number. The new comedy was a still further modification which comedy first assumed in the age of Alexander. Its distinguishing characteristic was, that all its characters were fictitious. The earliest writer was Philippides, who flourished about 323. The two most celebrated names were Philemon and Menander, the former of whom wrote 97, and the latter 105 plays. Numerous fragments of Menander, some of them of considerable length, show the elegance of his style and the variety and vigor of his genius. The last poet of the new comedy was Posidippus, who began to exhibit in 289; he wrote more than 50 pieces. The fertility and excellence of the Greek dramatic literature were most remarkable. The Dionysiac festivals, celebrated at Athens in the spring, were the principal occasion on which new pieces were brought out, and always in competition for the prize, and under the direction of the chief magistrates. The emulation thus excited among men of the highest genius gave a wonderful impulse to this species of composition, the originality and extent of which have always appeared so surprising.—The prose compositions that belong to this age were equally distinguished by their appropriate excellences. In history, we have Thucydides, born about 471, whose work on the Peloponnesian war is not only the first specimen of what has been called philosophical history, but remains unsurpassed down to the present time. Xenophon was born about 444. His historical works, though not equal to that of Thucydides in vigor of coloring and depth of reflection, yet are adorned with every grace of narrative and description. His other works are valuable for the light they throw on the spirit of Greek institutions and the peculiarities of Greek life. Of the works of Ctesias, Philistus, Theopompus, and Ephorus, which belong to a period somewhat later, none have come down entire. In philosophy, to which the teachings of Socrates (born in 469) gave a great impulse, we have the writings of Plato (about 429) and his pupil Aristotle (384). Plato was endowed with a brilliant imagination, and loved to soar into the highest region of speculation. His sense of the beautiful was exquisite; and his style was at once idiomatic and lofty, while in passages it moved with a rich and stately music which all ages have admired. Aristotle was a student and observer; practical results were the object of his investigations. His style was terse, logical, close, seldom adorned with poetical embellishments, and never with rhetorical exaggerations. Everything he wrote embodied the results of careful and extensive observations. He never entered the world of ideas with Plato. His views were comprehensive, and his exposi-

tions, except where the writing evidently contains only the heads of his discourses, are singularly clear. His works embrace the subjects of logic, rhetoric, physics, metaphysics, natural history, and politics. Plato founded the Academic school, whose point of reunion was the academy, on the Cephissus, north of Athens; Aristotle established the Peripatetic school, in the lyceum, near the Ilissus, on the opposite side of the city.—In the same period, political eloquence, always a characteristic form of Greek utterance, reached its highest perfection. In Homer we find not merely traces of eloquence, but admirable specimens. Public discussion was the general rule in the Greek republics. In Athens especially the statesman could not maintain himself, or exercise the smallest influence, without the faculty of public speaking. The historians relate the speeches of statesmen and generals. Thucydides describes the debates at Athens and elsewhere, on the questions that preceded and the events that occurred in the Peloponnesian war. Herodotus and Xenophon abound in speeches and orations; Solon, Pisistratus, Miltiades, Aristides, Themistocles, and Pericles were orators as well as legislators, counsellors, and generals. Pericles was the first to cultivate the art, and to adorn his mind with the teachings of philosophy and general literary culture. We have no exact report of any of the speeches of this class of statesmen, though Thucydides undoubtedly gives us the substance of several of the most important of those of Pericles. The rhetorical art in its technical character originated in Sicily; and the first rhetorical school at Athens was opened by Gorgias of Leontini. Other sophists and teachers of rhetoric were Protagoras, Prodicus, Hippias, &c. The peculiar judicial system also of Athens made a great demand for the rhetorical talent. The Athenian orators, whose works are extant in whole or in part, are Antiphon, Andocides, and Lysias in the 5th century; Isæus, Isocrates, Lycurgus, Hyperides, Æschines, Demades, Demosthenes, and Dinarchus in the 4th. The orations of these men present every variety of excellence, from the subtlest legal argument to the most passionate appeal. Demosthenes combines all the excellences of all the others, with some that are peculiar, at least in degree, to himself.—After the death of Alexander the Great, although literature continued to be cultivated in Greece, and especially in Athens, the rhetorical and philosophical schools holding an eminent position for centuries, yet till the Roman conquest the principal seat of letters and science was Alexandria, under the Ptolemies in Egypt. This period is called the Alexandrian age. Its characteristics were erudition, criticism, and the study of science; and in poetry the only original species was the bucolic or the idyl. The principal poets were Bion of Smyrna, Theocritus, Aratus (epic), Lycophron (author of "Cassandra"), Callimachus (epic, hymns), and Moschus. The bucolic poets are

picturesque and pleasing. During the Roman supremacy, and down to the introduction of Christianity, the principal poet was Nicander; the most important prose writers were Polybius, Apollodorus, Dionysius Thrax the grammarian, Diodorus Siculus, Dionysius of Halicarnassus, and Dionysius Periegetes. From this period to the close of the Roman empire in the West, there are two parallel series of writers, the pagan and the Jewish and Christian. Of the former, the most important are Babrius, Strabo, Epictetus, Plutarch, Dion Chrysostomus, Arrian, Polyænus, Pausanias, Marcus Antoninus, Aristides, Lucian, Pollux, Diogenes Laërtius, Achilles Tatius, Dion Cassius, Athenæus, Herodianus, Philostratus, Plotinus, Dexippus, Longinus, Palæphatus, and Iamblichus; of the latter, Philo, Josephus, the authors of the books of the New Testament, Clement of Rome, Justinus, Polycarp, Irenæus, Clemens of Alexandria, Origen, and Athanasius.—During the period extending from the establishment of the seat of government at Constantinople, A. D. 330, to the beginning of the reign of Justinian I. (527), it was common to paraphrase the books of the Old and New Testaments, and to versify the lives of Christian martyrs. The best of this class of productions came from Egypt, though the empress Eudocia and Basil the Great, bishop of Constantinople, were also quite successful in it. Quintus of Smyrna undertook to furnish some additions to the Iliad, but in spite of his evidently faithful study of Homer's diction, he was not able to equal it in conciseness and force. Cyrus of Panopolis and Nonnus are the most distinguished poets of this period; next to them rank Tryphiodorus, Coluthus, Muséeus, and Christodorus. The strangest production of this age is the so-called *ᾠηροποιήματα*, which give the life of Jesus in a kind of Homeric versification, and which are said to have been written either by the empress Eudocia or by Pelagius. The most distinguished ecclesiastical writers were Cyril, Basil, Chrysostom, Eusebius, Gregory Nazianzen, and Theodoret. The historians treated principally the history of the eastern empire, and the only work of this kind that has come down to us in a somewhat complete condition is Zosimus's account of the empire during the first four centuries. Next in importance is the ecclesiastical history of Socrates. Of Eusebius, Olympiadorus, Priscus, Candidus, Malchus, and Hesychius of Miletus, we have only a few fragments. The *Πίναξ τῶν ἐν παιδείᾳ ὀνομαστώ*, ascribed to Hesychius, is considered a forgery. Marcianus's Periplus and a geographical dictionary by Stephanus of Byzantium were the most prominent geographical works. The finest style was displayed in rhetoric. Himerius of Bithynia was considered a rhetorician above comparison, though the emperor Julian and his teacher Libanius appear to modern criticism far superior to him. Synesius and Procopius show that the art was beginning to decline. Works of imagination came prin-

cipally from the pens of Longus, Heliodorus, Achilles Tatius, Xenophon of Ephesus, and Eumathius, of whom the last is the poorest in invention, but the most prodigal with the coloring of Syrian diction. The grammarians Chæroboseus, Theodosius, Orion, and Hesychius were less devoted to independent studies than to copying diligently the works of their predecessors; and the bulky compilations of Hesychius are still of value.—The next period is that of mediæval Greek literature, extending to the conquest of Constantinople by the Turks in 1453. The abolition of the pagan schools by Justinian closed also the literature of paganism; nevertheless this period contains rather the history of the decay than of the growth of a literature. After Procopius, the only one who combined a profound knowledge of the political affairs of his country with simplicity of style, and after Agathias, who endeavored to imitate Procopius, there followed a small number of historians, like Petrus, Hesychius, Nonnosus, Theophanes, and Menander Protector, whose productions are neither trustworthy nor entertaining. The chronicle of Syncellus is the most important. The Egyptian Theophylactus Simocattes, the Hellene Georgius Pisides, and the Syrian Malalas, are vile in diction and vulgar in sentiment. Geographical studies were represented by the friar Cosmas Indicopleustes, who devised a new system to harmonize with the Bible. The best minds prosecuted juridical studies, such as Tribonianus, Dorotheus, Theophilus Antecessor, Theodorus, Stephanus, Cyrillus, Philoxenus, and others. During the 8th and 9th centuries, the period of iconoclasm, literature could be cultivated but little, and the preservation or tradition of many a Greek author is entirely owing to the literary tastes prevailing at the time in Armenia, Syria, and Egypt. The most celebrated man of the second half of the 9th century was Photius, the teacher of Leo the Philosopher; but the literary spirit developed during this period is best represented by Constantine VII. Porphyrogenitus, who collected all the literary productions of the past, whether valuable or worthless, long or short, and had them copied by a number of savants into a kind of cyclopædia of 53 books. New literary productions became exceedingly scarce, and the few that made their appearance were surprisingly deficient in logic, taste, and language. Among them may be mentioned the chronicles and memoirs of Leontius the younger, Genesius, Leo Grammaticus, Xiphilinus, Hippolytus, and Leo Diaconus, and above all the history of Anna Comnena. The manuscripts of this age swarm with errors in grammar and orthography. The chronicle of Simeon Sethos, toward the end of the 11th century, is considered the first monument in prose of modern Greek; but no poetical work is known that dates back further than the 12th century.—During the interval between the conquest of Constantinople and the struggle for independence in the 19th century, only

a very small number of literary productions deserve to be mentioned, aside from the works written in the service of the Greek church. In the 17th century the Greeks were admirers of a very weak idyllic form of poetry, especially of Drymiticos's "Beautiful Shepherdess;" but a few compositions made their appearance which aimed at a more artistic style, and which were more elevated in sentiment, like the "Hel-las" by Allatios. In a strict sense the literature of modern Greece cannot be considered older than the latter part of the 18th century, when Constantinos Rhygas sent out the patriotic songs that invigorated the national spirit of the Greeks. His most celebrated production is the imitation of the *Marseillaise*, beginning *Δεῦτε παῖδες τῶν Ἑλλήνων!* Adamantios Corais, often designated as the father of the literature of modern Greece, may more deservedly be called the literary Hercules of Greece, being a very prolific writer of medical treatises and translator of the classics. It is often asserted, but not equally evident, that he produced a revolution in the language of modern Greece. "His linguistic reform was a very simple one," says Geldart; "he proposed to use the classical terminations wherever these were not altogether obsolete, in preference to those which prevailed in the mouths of the common people." The Greeks were not slow to follow his rule and the example which he set. Accordingly, the language of the books is somewhat different from that of the people of Greece. On the threshold of the 19th century stand Christopulos, Piccolos, and Rizos-Nerulos as writers of lyric songs, tragedies, and comedies, which are characterized by a comparatively pure diction, and also by imitations of French standards. The poetry of Christopulos, whom the Greeks designate as the modern Anacreon, was successfully imitated by the brothers Alexander and Panagiotis Sutsos, Calvos, Solomos, and Angelica Pally. Other poets of the present time who deserve to be noticed are Alexander Rizos Rangavis or Rangabe, Orphanidis, Carasutsas, Valaoritis, Zalocostas, Naphtis, Vlachos, and Antoniades. The sciences are represented principally by translations of the most noted works of the Occident, but original works are rapidly increasing. Historical works have been published by Paparigopulos, Cumas, Sutsos, Tricupis, Philimon, Levkias, Zampe-lios, Surmelis, Venizelos, and Sathas. On the geography of various countries have written Philippidis, Constantas, Scarlatos Byzantios, Valetas, and Rangavis. Writers on archæology are Pantazis, Pittakis, Rangavis, and Lambros. Contributions to philology are furnished by Neophytos Ducas, Darvaris, Bambas, Asopios, Philip Joannou, Gennadios, Bernardakis, and Galanos. The most celebrated mathematicians are Vaphas, Pyrrhos, and Zochios. Theological and philosophical writers are Apostolidis, Contogonis, Adamidis, Kyriacos, and Agathangelos.—See Browne's "History of Classical Literature" (London, 1851); Mure's

"Critical History of the Language and Literature of Ancient Greece" (1854-'67); K. O. Müller's "History of the Literature of Ancient Greece," continued by J. W. Donaldson (1858); and Nicolai, *Geschichte der griechischen Literatur* (Magdeburg, 1865).

**GREECE, Wines of.** As a wine-producing country Greece no longer maintains the reputation which she enjoyed in ancient or even in comparatively modern times. With a climate admirably adapted to the culture of the grape, the area devoted to that purpose has steadily diminished. Among the causes which have contributed to this result are the impoverished condition of the soil of large tracts, formerly well wooded and watered, and the rude systems of viticulture in general use. With the destruction of its ancient forests parts of the country are gradually becoming an arid desert; and desolating wars, brigandage, and other internal troubles have combined to restrict the development of its agricultural resources. In consequence, the production of wine in Greece, which was still considerable during the Venetian supremacy in the 15th and 16th centuries, has dwindled to a comparatively insignificant amount. In like manner vinification has deteriorated to such a degree as to make Greek wines compare disadvantageously with those produced in much less favored localities. They contain, as a rule, a large amount of acetic acid, and many of them are rapidly converted into vinegar. To prevent this result various primitive practices are resorted to, such as smoking with wood smoke or vapor of resins, pitching the barrels, or adding gypsum, chalk, salt, &c., which render many of the wines unpalatable.—The country lying between the Turkish frontier and the isthmus of Corinth produces comparatively little wine of repute, the principal vineyards being near Lepanto, Chæronea, and Megara, and on the slopes of Mt. Poliguna. The plain surrounding Mt. Hymettus, in the neighborhood of Athens, yields a wine which has been favorably mentioned by European connoisseurs. The Morea or ancient Peloponnesus, notwithstanding many disturbing causes, continues to produce considerable quantities of wine, of which that made near Pergos, amounting to about 1,500,000 gallons annually, is esteemed the best. Nauplia, called also Napoli di Malvasia, situated on the gulf of Nauplia, is noted as the place whence the Malvasia or malmsey wines derived their name. The vineyards suffered greatly during the Greek war of independence, and are now of little value. The islands of the Greek archipelago, and those in the Mediterranean colonized by the Greeks, were in ancient times more famous for their wines than the mainland, and their superiority in that respect is fully maintained at the present day. Of the islands of the archipelago, Santorin, the ancient Thera, is the most luxuriant. It is of volcanic origin, forming an imperfect ring, with the crater filled by the sea. The external slopes

furnish the wine lands, and every available piece of soil is under cultivation. The wines produced are white and red. The best red growth, known as Santorin, partakes of the nature of both port and claret, and is highly esteemed. Among the white varieties are the Thera, and a wine called the "wine of the night," of which two qualities are known to commerce, the Caliste and St. Elie, both rich and full-bodied. There is also a fragrant muscadine wine, known as the *vino santo*, and an amber-colored variety called the "wine of Bacchus." All of these wines doubtless preserve many of the qualities which made them acceptable to the civilized nations of antiquity. In ordinary seasons the island produces from 10,000 to 11,000 pipes, most of which goes to Russia. Next in importance are the yields of Zea (Ceos), Scio (Chios), Tenedos, and Samos, all but the first of which belong to Turkey. The Samian wine, notwithstanding the eulogistic allusion to it in Byron's verses, was considered by the ancients scarcely equal to the produce of some of the other islands. At the present day Tenedos is wholly devoted to the culture of the grape; its annual production is about 1,400,000 gallons, which is exported to Constantinople, Smyrna, and Russia, and is the common table wine of the Orient. The Ionian islands produce a considerable amount of dry and sweet wines. Those of Corfu are light and delicate, and those of Ithaca rich and luscious. All the wines of this group are plastered. The growths of Crete, Rhodes, and Cyprus, although Turkish dependencies, also come under the head of Greek wines. Crete, famous in ancient times for the abundance and excellence of her wines, is still a large producer, and for centuries her specialty has been Malvasia, the white sweet wine once universally drunk in western Europe under the name of malmsey. During the Venetian supremacy Crete and Cyprus supplied Europe with their choicest dessert wines, and the export of the former is said to have amounted to 200,000 casks annually. The principal vineyards are near Canea, Kisamos, Sphakia, and Candia. The wines of Cyprus are of three classes. The first consists of the wines of the commandery of the knights templars, made in the neighborhood of ancient Paphos, and which have a bouquet resembling the flavor of bitter almonds, said to be communicated to them by spices; the second is a sweet muscat, and the third a common wine, at first pale red, but which becomes colorless with time. These wines are fermented and matured in earthen vessels which preserve the shape of the ancient amphoræ. The vintage of the island has declined to less than a fifth of its production two centuries ago. Rhodes produces sweet and luscious wines from grapes of the size of plums.

**GREEK CHURCH** (also called the Greek Catholic, the Orthodox Greek, the Orthodox, or the Eastern church), that part of the Christian church which adheres only to the doctrinal de-

crees of the first seven œcumenical councils (of Nice, 325; Constantinople, 381; Ephesus, 431; Chalcedon, 451; Constantinople, 553 and 680; and Nice, 787), of the so-called Quinisextum of Constantinople, held in 692, and of the council held at Constantinople under Photius in 879 and 880, while it rejects the authority of all the succeeding councils recognized by the Roman Catholic church as œcumenical. A dogmatical difference between the Greek church and the church of Rome arose as early as 482, when the emperor Zeno endeavored to reconcile the Monophysites with the Catholic church by publishing a creed called the *Henoticon*, in which the disputed articles were entirely avoided. Felix II., the bishop of Rome, excommunicated the patriarchs of Constantinople and Alexandria for having been instrumental in issuing the *Henoticon*, and thus actually severed the communion between the churches of the East and of the West. The altered disposition of the court of Constantinople enabled Pope Hormisdas in 519 to restore the union, which however never became very firm again, and was repeatedly interrupted by decisions of the emperors in matters of faith, against which the bishops of Rome protested. The adoption in the western church of an article which declared that the Holy Spirit proceeded from the Son as well as the Father (*Filioque*), and its incorporation in the confession of faith at the synod of Toledo (589), constituted another point of dogmatic difference, although it did not awaken opposition in the Greek church until some time in the 8th century. Still more than these dogmatic differences, political and hierarchical reasons prepared a dissolution of the union. The patriarchs of Constantinople, to whom the councils of Constantinople (381) and Chalcedon (451) had assigned the second place among the patriarchs of the Catholic church, strove to obtain the first. The emperors claimed in the settlement of the numerous dogmatical controversies of the East a power which the bishops of Rome denied to them. The more Rome and Italy became politically estranged from the East, the more intolerable became the exercise of the supreme authority on the part of the bishop of Rome. A temporary dissolution of the union again took place in 732, when the pope condemned iconoclasm, which was approved of by several emperors, and by a synod of Constantinople in 754. More serious than ever before became the conflict between the two churches when the patriarch Photius, whose accession in 858 was due to the influence of the court, was rejected by Pope Nicholas I. as an intruder. A circular was then sent forth by Photius, censuring the observance of Saturday as a fast, the use of eggs and cheese during the first week in Lent, the administration of confirmation exclusively by bishops, the prohibition of the marriage of priests, and the use of the words *Filioque* in the Nicene creed. At a synod convened by Photius at Constantinople in 867 the pope was

excommunicated and deposed. Besides these errors, the Roman church was charged with having drawn the Bulgarians into ecclesiastical connection with Rome, though they had been converted by Greeks. Since Photius the relations of the eastern church to that of Rome have never been reestablished in a definite form, though the great schism was not fully declared before July 16, 1054, when Roman legates deposited on the great altar of the church of St. Sophia at Constantinople the sentence of excommunication which had been issued against the patriarch Cæcarius, who in 1053 had added to the former charges of heresy brought against the Roman church that of using unleavened bread in the eucharist. At the council of Lyons (1274) Michael Palæologus allowed his representatives to subscribe to the Roman confession of faith, as he hoped thus to obtain aid against the Turks from the West; but when Pope Martin IV. excommunicated the emperor (1281), Greek synods held at Constantinople in 1283 and 1285 reaffirmed the independence of the Greek church. For the last time a union between the two churches was consummated at the synod of Florence (1439), by the Greek emperor and the patriarch himself. But the people and the great body of the inferior clergy were entirely strangers to any such union, and the conquest of Constantinople (1453) made the hostility of the Greek church to Rome still greater. The Roman Catholic church never ceased in its endeavors either to bring about a corporate union, or to gain over individual Greek congregations. Numerous Latin convents were established in the East, and in Calabria the Orosinian seminary was founded by Clement XII. for this special purpose. They succeeded in organizing a Greek United church, which acknowledged the supreme authority of the pope, while on the other hand it was permitted to abide by all the peculiar usages of the Greek church which did not affect fundamental doctrines, as marriage of the priests, reception of the Lord's supper in both kinds, use of the Greek language in the divine service, &c. In Russia, however, almost all the dioceses of the United Greek church were induced, under the reigns of Catharine II. and of Nicholas, again to dissolve their connection with Rome, and to pass over to the Russian church. It was believed that a portion of the clergy and of the people were opposed to this change of ecclesiastical relations, and several congregations in 1858 petitioned Alexander II. for permission to return to the United Greek church; but this was not granted, and that church in 1873 had become almost extinct in the Russian dominions. In general, the clergy and people of the Greek church have at all periods showed themselves decidedly hostile to a union with Rome, and numerous controversies, such as that under the patriarch Dositheus in Jerusalem on the holy sepulchre (1674), as well as the yearly repeated excommunication of the pope and

of his adherents, kept up this spirit of hostility. When, therefore, Pius IX. in 1848 again invited by an encyclical letter the entire eastern church to a corporate union with Rome, his proposition was rejected; and the invitations which in 1869 were addressed by the pope to the Greek bishops to attend the Vatican council were unanimously declined. There seems to be in the Greek church not even any organized party, as in most of the other eastern and some of the Protestant churches, which hopes and labors for a future union with the Roman Catholic church. The return to the Roman communion of numbers of the high Russian nobility, and the establishment of such societies as those of St. Dionysius in Turkey and St. Peter in Germany for effecting a reunion of the churches, have led to no appreciable result. The Protestants early sought to establish friendly relations with the Greek church. Melancthon in 1559 sent a Greek translation of the "Confession of Augsburg" to the patriarch of Constantinople, and in 1574 an epistolary correspondence on this confession took place between the theologians of Tübingen and the patriarch Jeremiah II., yet without success. Cyril Lucaris, who leaned toward Calvinism, was strangled in 1638. In modern times the Greek church has shown itself, in general, very hostile to the Protestant missionary schools, and to the Bible societies, though its literature shows a strong influence of Protestantism; a periodical, sympathizing with the principles of Protestant Christianity, was established at Athens in 1858, and found a large patronage. The high-church party in the church of England, which recognizes the Greek church as an orthodox branch of the church of Christ, sought to obtain from the Greek bishops the same recognition for itself, and the establishment of a closer intercourse, and a special society was established for promoting intercommunion between the two churches. The idea has found many zealous friends among the eastern bishops, and a friendly correspondence has sprung up between the dignitaries of the two churches, in which even the archbishop of Canterbury and the patriarch of Constantinople have taken part. The Greek church has manifested a profound interest in the progress of the Old Catholic movement. Prominent clergymen of that church attended and addressed the congresses held by the Old Catholics of Germany, and the hope was generally expressed that the movement might lead to the reunion of the eastern and western churches.—The internal history of the Greek church since its separation from the Roman Catholic is almost entirely destitute of great events. In 1588 Russia received an independent patriarchate, whereby the spiritual supremacy which the patriarch of Constantinople had virtually exercised over the church was abolished. In 1833 a synod of 36 Greek metropolitans, held at Nauplia, declared the orthodox eastern church of Greece independent

of every foreign authority; and in 1850 this independence was recognized by Constantinople. A great commotion within the Greek church of Turkey was subsequently caused by the Bulgarian nationalists, who objected to the appointment of non-Bulgarian bishops over Bulgarian dioceses. The Turkish government at length yielded to their demands, and organized a number of Bulgarian dioceses into an exarchate. A synod held in Constantinople in 1872, and attended by the patriarchs of Constantinople, Antioch, Jerusalem, and Alexandria, excommunicated the entire Bulgarian church organization, which, however, had the sympathy of the Russians. Dogmatic controversies rarely occurred, and a formation of new sects took place only in Russia, called forth not so much by doctrinal differences as by opposition to liturgical and hierarchical changes in the state church. With regard to other Christian denominations, as well as to Mohammedanism, paganism, and Judaism, the Greek church has kept itself almost exclusively on the defensive. In Russia, however, the government has succeeded in converting a large number of its non-Christian population, especially in Siberia, to the Greek church. The theological literature of the Greek church is not extensive; none of its works have ever been of marked influence on Roman Catholic or Protestant theology. During the present century, however, the number of ecclesiastical seminaries has considerably increased, and the periodical literature is also multiplying.—The Greek church recognizes the Bible and tradition as rules of faith; the latter, however, only so far as it is in accordance with the first seven oecumenical councils and the synods held at Constantinople in 692 (known among Latin canonists as the "council in Trullo" or Quinisextum), and in 879-880, presided over by Photius. A system of the doctrines of the Greek church, more complete, and, on account of its application of Aristotelian formulas, more scientific than any similar work in the Latin church up to that time, was compiled by the monk John Damascene (died about 760). The most important confessions of faith are: 'Ορθόδοξος Ὁμολογία τῆς Πίστewς τῆς Καθολικῆς καὶ Ἀποστολικῆς Ἐκκλησίας τῆς Ἀνατολικῆς, or *Confessio Orthodoxa*, by Petrus Mogilas, metropolitan of Kiev (also called the Russian catechism), published in 1640; and Ἀσπικὴ Ὁρθοδόξιας, or *Synodus Hierosolymitana*, under Dositheus, in 1672. The former, which in 1643 was signed by all the Greek patriarchs, and solemnly recognized at the synod of Jerusalem in 1672 as the confession of faith of the oriental church (published in Greek and Latin, Amsterdam, 1662; Leipzig, 1695; in German by L. Frisch, Frankfurt, 1727), has everywhere, especially in Russia, symbolic authority. The latter was signed by 67 bishops and clergymen. None of the other books sometimes regarded as symbolical (*e. g.*, the two confessions of the patriarch Gennadios in Constantinople, and the confession of the

patriarch Jeremiah of 1580) has obtained so general a symbolic authority, and the confession of Metrophanes Kritooulos of 1661 is only a private letter. (See Kimmel, *Libri Symbolici Ecclesiae Orientalis*, Jena, 1843, and appendix to this work by Weissenborn, 1850.) Plato, a Russian archbishop and president of the academy of St. Petersburg, was the author of a catechism which in many points differs from that of Petrus Mogilas, and is less hostile to Protestantism. The Greek church holds in common with the Roman Catholic the doctrines of seven sacraments, of the sacrifice of the mass, of the veneration of the Virgin Mary, the saints, images, and relics, of the meritoriousness of fasting and other works, the hierarchical degrees of ecclesiastical orders, and monasticism. Its peculiar tenets are mainly the following: It disowns the authority of the pope, and, in controversies of faith, acknowledges the infallibility of oecumenical councils. At Constantinople baptism by immersion only is admitted as valid; but the Russian church considers baptism by immersion as a matter of rite, not of dogma. It administers the Lord's supper in both kinds, and gives confirmation and communion to children immediately after baptism. It denies the existence of a purgatory, yet prays for the dead, that God would have mercy on them at the general judgment. It maintains that the Holy Ghost proceeds from the Father, as principal, through the Son as medium. It admits of no images in relief or embossed work, but uses paintings and engravings in copper or silver. It approves of the marriage of priests, provided they enter into that state before their admission into holy orders; it condemns second marriages of priests, and fourth marriages of laymen. It keeps four fasts in the year more solemnly than the rest.—The churches are mostly built in the form of a cross. The altar stands toward the east under a vault which is higher than the nave, and separated from it by a partition board containing three doors, the middle of which is called the sacred door, and when opened permits the altar to be seen. At the beginning of the canon of the mass the doors are closed, and are not opened again until after the communion of the priest and deacon. Benches are not used, as the people stand during divine service, using a kind of crutch as a support. The principal act of worship is the mass, which all are bound to hear every Sunday. Only one mass a day is said in each congregation, and that before the rising of the sun. The liturgy used at the mass is known as that of the apostle James and Basil the Great. This work was again abridged by Chrysostom, and in this shorter form, which, however, has likewise undergone some changes in the course of time, it is used on common days, while the longer liturgy of Basil is still used at some of the higher festivals. The sermon, which is considered unessential, was formerly very rare, and consisted generally of a homily read from old collections.

The priests of Russia began in 1682 to preach their sermons instead of reading them from books, and gradually it became the general practice to preach at least twice a year. In 1858 many of the churches of St. Petersburg introduced the custom of having a sermon every Sunday. All the sermons, however, had to be submitted to the previous examination of the bishops, which censorship was abolished in the diocese of St. Petersburg at the beginning of 1859. Festivals peculiar to the oriental church are the consecration of water on Jan. 6, in commemoration of Christ's baptism, and the Orthodox Sunday, on which a curse is pronounced against all heretics. It is forbidden to use instrumental music in the churches, but the mass is generally accompanied by choirs of singers. Catechising is something rare, and the arrangements for religious instruction are very imperfect. The language used at divine service is among the Greeks of Turkey and Greece the old Greek, among the Russians and other Slavic nations the old Slavonic, and among the Georgians the old Georgian.—The clergy are divided into two classes, the higher and the lower clergy. The former class comprises the patriarchs, metropolitans, archbishops, and bishops; all of whom are chosen from among the monks, and must live in celibacy. The lower clergy are subdivided into the black clergy (so called after their dress) or monks, and the white or secular clergy, who wear blue, violet, or brown dresses. A convent is governed by an abbot or archimandrite (ἀρχιμανδρίτης); and among the other monks there are priors (ἡγούμενοι), priests (ιερομοναχοί), and deacons (ιεροδιάκονοι), who can perform the same functions as the priests and deacons of the secular clergy. All the others are merely called monks (μοναχοί). The lower secular clergy are protopopes (πρωτοπopeί, arch priests), popes (priests), deacons, subdeacons, and lectors. The monks of the Greek church, as well as the nuns, who are less numerous, generally follow the rule of St. Basil, with the exception of those of Mt. Sinai and Mt. Lebanon, who follow the rule of St. Anthony. At the head of the female convent stands an *oikonomos*, who must be at least 80 years of age. He chooses a priest as confessor of the nuns, who also elect, under his presidency, an abbess (ἡγουμένη). The most celebrated convents are those of Mt. Athos, the convent of the holy sepulchre in Jerusalem, and that of Mt. Sinai in Arabia.—With regard to church constitution, the Greek church is made up of ten independent groups. I. The church of Constantinople is governed by a patriarch, who bears the title of "Most Holy Archbishop of Constantinople, New Rome, Œcumenical Patriarch." He has under him 129 bishops, of whom there are seven in Roumania, four in Servia, and one at Venice. The churches of Roumania and Servia incline to make themselves independent of Constantinople; and the Bulgarians, after many years of agitation, have at last succeeded in obtaining

from the Turkish government the establishment of a Bulgarian exarchate, which at first contained 12 dioceses, and which, on certain conditions legally provided, may be joined by any other dioceses in which the Bulgarians are predominant. The dioceses of the Ionian islands were, in consequence of the incorporation of the islands with Greece, transferred from the church of Constantinople to that of Greece. Throughout the immediate possessions of the Sublime Porte (*i. e.*, all European and Asiatic Turkey except Roumania and Servia) the patriarch of Constantinople has not only spiritual, but also a kind of temporal jurisdiction, as he is considered by the Turkish law the head of all the Greek Christians, who have to pay to him a yearly tax. He presides in the synod, the highest ecclesiastical board, which governs the Greek church of Turkey, and consists of all the patriarchs and a certain number of archbishops (properly 12), who have to take up their permanent residence at Constantinople. In certain cases, as the election of a patriarch, the holy synod has to act in union with the national assembly, a number of representatives of the most distinguished Greek families of Constantinople. The *hatti-humayum* of Feb. 21, 1856, provided for important changes in the relation of the patriarchs and the holy synod to the Greek church. They were to receive a fixed salary, to lose their temporal and judicial power, and the patriarchs and bishops were to be appointed for life. A supreme church council, to consist of priests and laymen, was to be elected by the entire church. II. The church of Alexandria counts five bishops, under the "Blessed and Holy Patriarch of the great city of Alexandria, of all Egypt and Pentapolis, of Libya and Ethiopia, Pope and Judge Œcumenical." The patriarch habitually resides at Cairo. III. The church of Antioch numbers 17 bishops. Its chief bears the title of "Blessed and Holy Patriarch of the City of God, Antioch, Syria, Arabia, Cilicia, Iberia, Mesopotamia, and all the East, Father of Fathers and Pastor of Pastors." IV. The church of Jerusalem has 14 bishops. The patriarch is called the "Blessed and Holy Patriarch of the Holy City of Jerusalem, of Palestine, Syria, Arabia beyond Jordan, Cana Galilee, and Holy Sion." V. The Russian church has 60 bishops, governed by the "Most Holy Synod directing all the Russias," which was first established by Peter the Great, and consists of three metropolitans, one archbishop, two other clerical and two lay members. VI. The church of the island of Cyprus counts four bishops, under the "Blessed and Holy Bishop of New Justiniana and of all the Isle of Cyprus." His see is at Nicosia. VII. The Greek church of Austria is divided into three jurisdictions entirely independent of each other. In the lands of the Hungarian crown there is a metropolitan for the Serb nationality at Carlovitz, and another for the Rouman nationality at Hermannstadt; there

are besides eight bishoprics. The Greek church of Cisleithan Austria has an archbishop (since January, 1873) at Czernowitz, and bishops at Zara and Cattaro. VIII. The church of Mt. Sinai has only one bishop, the "Blessed Archbishop of Sinai." IX. The church of Montenegro likewise has but one bishop, called "Metropolitan of Scanderia and the Seashore, Archbishop of Cettigne, Exarch of the Holy See of Ipek, Lord of Montenegro and of Berda." He had formerly both spiritual and temporal power, but recently the jurisdictions have been divided. The present bishop was induced by the Russian government to go to St. Petersburg, and not, as was done by his predecessors, to Constantinople, to receive episcopal consecration. X. The Hellenic church, in the kingdom of Greece, numbers 31 archbishops and bishops, governed by the "Holy Hellenic Synod" of Athens. The presidency of this board belongs by right to the metropolitan archbishop of Attica and Bœotia, residing in Athens. This board was established in 1852, and consists of five prelates of the kingdom. They meet annually in September, and have to take an oath of fidelity to the king before beginning their proceedings. All these ten divisions of the orthodox church recognize the supreme authority of a general council; but as no general council has been assembled for 1,000 years, they do not agree on the conditions required to make a council really œcumenical. In addition to these ten divisions, which recognize each other as orthodox, there are in Russia a number of sects, most of which fully acknowledge the doctrinal basis of the Greek church, but reject the liturgy of the Russian church as corrected by Patriarch Nikon (1654), and therefore keep aloof from any intercourse with the state church. By the state church they are called *Raskolniki* (separatists), while they call themselves *Starovierti* (of the old faith). The number of these sects dissenting from the state is large. They also differ widely from each other, and some of them have placed themselves in open opposition not only to the liturgy and the government of the Russian church, but also to the doctrines of the Greek church in general. As from their origin they have been incessantly subjected to persecution, their peculiarities are but imperfectly known. The great argument employed against those of them who adhered to the orthodox doctrine of the Greek church was, that the true church is essentially episcopal; therefore they, having no bishop, could not be the true church. Some years ago, however, the Greek bishops of the Austrian empire ordained for them a bishop. The former rigor of the Russian government against them has been mitigated since the accession of Alexander II., and in 1859 an imperial decree even prescribed that the bishops of the state church shall in future ordain the priests and bishops of the *Raskolniki*.—The Greek church predominates in all Russia, Eu-

ropean Turkey, Greece, and Montenegro, and its area is continually extending by the progress of Russia in central Asia. The number of Greek Christians in Russia amounts to about 54,000,000. This, however, includes the sects, whose number is estimated at from 5,000,000 to 15,000,000. Turkey numbers about 12,000,000 inhabitants belonging to the Greek church, of whom 4,275,000 belong to Roumania, and 1,295,000 to Serbia; Austria (according to the census of 1871), 3,050,000; the kingdom of Greece, 1,440,000; Montenegro, 125,000; Germany, about 3,000. In all other countries only a few Greek churches are found, nearly all of which are connected with Russian embassies. Thus the whole population connected with the Greek church in 1874 was about 74,300,000. The greatest number of United Greeks is in Austria, nearly 4,000,000; Turkey has about 50,000; Russia, 229,000; southern Italy, 80,000. They were formerly very numerous in Russia, where under the Polish rule a considerable portion of the church acknowledged the supremacy of the pope at the synod of Brzesc or Brest (1596). But most of them returned to the Russian state church under the reign of Catharine II., and the remainder at a synod in Polotzk in 1839. The total number thus lost by the Roman Catholic church in Russia is estimated at about 10,000,000. The Greek United church in Austria has two archbishops and six bishops; in Turkey, one patriarch (of Antioch) and eight suffragans; in Russia, one bishop at Chelm.—See Chytræus, *De Statu Ecclesiarum hoc Tempore in Græcia* (Rostock, 1569); Leo Allatius, *Græcia Orthodoxa* (2 vols., Rome, 1652 and 1659); Thomas Smith, *De Ecclesiâ Græcâ Statu Hodierno* (London, 1678); Le Quien, *Oriens Christianus* (3 vols., Paris, 1740); Wenger, *Beiträge zur Kenntniss des gegenwärtigen Geistes der Griechischen Kirche* (Berlin, 1839); H. J. Schmitt, *Kritische Geschichte der Neugriechischen Kirche* (Mentz, 1840); Wiggers, *Kirchliche Statistik* (2 vols., Hamburg, 1843); *L'Église orthodoxe d'Orient* (Athens, 1853); J. M. Neale, "History of the Holy Eastern Church" (London, 1847 *et seq.*); Dean Stanley, "Lectures on the History of the Eastern Church" (London, 1861; New York, 1870); Silbernagl, *Verfassung und gegenwärtiger Bestand sämtlicher Kirchen des Orients* (Landshut, 1865); and Gagarin, *Le clergé russe* (Paris, 1871).

**GREEK FIRE**, a name applied to compounds that burn on the surface of or under water. A summary of what is said about it in old writers is given by Gibbon in the "Decline and Fall of the Roman Empire," chap. lii. The subject is also ably treated by Dr. McCulloch in vol. xiv. of the "Quarterly Journal of Science." The Greek fire was most advantageously employed in the defence of Constantinople during the two sieges by the Saracens of A. D. 668–675 and 716–718. The secret of its preparation and use was derived from Callinicus, a deserter from the service of the caliph to that of the emperor. It appears to have been a compound of

bitumen, sulphur, and pitch, and to have been poured from caldrons, or projected in fire balls, or on arrows and javelins around which flax was twisted saturated with the inflammable compound. It was vomited through long copper tubes from the prows of fire ships. These were themselves consumed, as they sent fire and destruction among the galleys of the enemy. For 400 years its secret was successfully preserved by the Romans of the East, the vengeance of heaven being imprecated upon whomsoever should divulge this composition, which the people were taught to believe was revealed by an angel to the first of the Constantines. The Mohammedans finally obtained the secret, and in the crusades turned the art against the Christians. Joinville in his *Histoire de St. Louis* describes the fire as coming through the air like a winged long-tailed dragon, about the thickness of a hog's head, with the report of thunder and the velocity of lightning, producing so much light from the quantity of fire it threw out, that one might see in the camp as if it had been day. Its use was continued till the middle of the 14th century, when it gave place to gunpowder.—M. Niepce de St. Victor experimented, by request of the French minister of war, upon the property of benzole of burning upon water and igniting if a bit of potassium or of phosphuret of calcium be contained in it. On this principle he made an inextinguishable lamp, to be ignited by immersion under water, for attachment to buoys and life preservers. He found that if a glass vessel containing 300 grammes of benzole and half a gramme of potassium were broken on the surface of the water, the benzole would immediately overspread a considerable surface, bursting at the same time into flame. A mixture of three parts of benzole and one of sulphuret of carbon, being put into a hand grenade previously heated by immersion in boiling water, produced a disengagement of vapor, which could be ignited and would continue to burn from a jet until the whole was consumed. Phosphorus in solution increases its power of setting fire to other objects. Petroleum may be substituted for the benzole. It was thought that this might be used in naval warfare as the ancient Greek fire was employed. It was tried by the Paris commune in 1871, under whose direction many thousand petroleum bombs were thrown with disastrous effect. The subject is fully treated by Scoffern in his "Projectile Weapons of War and Explosive Compounds" (London, 1858), in which he also names several liquid mixtures that spontaneously ignite, and may be used for the same purposes as Greek fire. A solution of phosphorus in sulphuret of carbon thrown in a glass grenade was found, in experiments conducted at Woolwich, to ignite soon after the liquid was scattered. Chloride of sulphur may be substituted for the sulphuret of carbon, the ignition not taking place quite so soon, thus giving time for the liquid to penetrate into woodwork and

canvas. An abominable odor is diffused during the combustion. The arsenical alcohol, described under KAKODYLE, is proposed for a similar purpose, the fumes from which would greatly add to its deadly effects.

**GREEK MYTHOLOGY.** See MYTHOLOGY.

**GREELEY.** I. A central county of Nebraska, formed since the census of 1870, drained by branches of Loup fork of the Platte river; area, 625 sq. m. II. An E. county of Dakota territory, recently formed, and not included in the census of 1870; area, about 900 sq. m. It consists mostly of table land, being largely occupied by the "Coteau des Prairies," and contains several small lakes.

**GREELEY,** a town of Weld co., Colorado, on the S. bank of the Cache à la Poudre river, a few miles above its junction with the South Platte, and on the Denver Pacific railroad, 50 m. N. by E. of Denver; pop. in 1870, 480; in 1874, about 1,500. It is situated about 30 m. E. of the Rocky mountains, and is the centre of a rapidly improving region, well supplied with coal, stone, and timber. It contains three tanneries, two saw mills, a grist mill, three hotels, two banks, a graded school building costing \$25,000, two weekly newspapers, a quarterly and a semi-annual periodical, and six churches. Greeley was founded in April, 1870, by the Union colony, which was organized in New York on Dec. 23, 1869, and was named in honor of Horace Greeley, one of its promoters. The colony purchased 12,000 acres of land, and took the preliminary steps to secure a large amount more from the government. The town site was divided into 483 business lots, 660 residence lots, and 81 lots reserved for churches, schools, &c. The adjoining lands were divided into sections of from 5 to 40 acres, and each colonist was allowed to select one. A public square of 10 acres, planted with trees and beautified with artificial lakes, was laid out in the centre of the town, and an island in the river just above the town, embracing 50 acres and covered with cottonwood trees, was reserved for public use. All deeds of property contain clauses prohibiting the manufacture or sale of liquor in any form. An extensive system of irrigation has been established. The valuation of town property in 1874 was \$850,000; of farming lands, \$1,500,000.

**GREELEY, Horace,** an American journalist, born in Amherst, N. H., Feb. 3, 1811, died at Pleasantville, N. Y., Nov. 29, 1872. His ancestors were Scotch-Irish. His father, Zaccheus Greeley, had settled on a small rocky farm, which he vainly tried to pay for and get a living from. Horace was a delicate and sickly child, but showed a remarkable appetite for learning. He could read almost as soon as he could talk, devoured all the books within reach, and so far surpassed his schoolmates that the leading men of the neighborhood offered to bear his expenses in a college course, which his parents declined for him. When he was ten years old the farm was sold by the sheriff, and

the family removed to West Haven, Vt. Horace had early conceived a strong desire to be a printer, and in 1826 he entered as an apprentice the office of the "Northern Spectator" in East Poultney, soon became an expert workman, and rendered occasional assistance in editing the paper. He kept up his studies, and was called the "giant" of the village debating society, being especially noted for his familiarity with political statistics. His parents meanwhile had removed to Erie co., Pa., and he had made two visits there, walking a large part of the way. In 1830 the "Spectator" was discontinued, and he went west in search of employment, finding it at Jamestown and Lodi, N. Y., and Erie, Pa. In August, 1831, he went to New York, reaching that city on the 17th, with \$10 in his pocket. He soon found employment by undertaking a job which no other printer would accept, it being a 32mo New Testament in very small type, with inter-columnar notes in still smaller. By working at this 12 or 14 hours a day he was able to earn but \$5 or \$6 a week, yet he persevered till the Testament was completed. He worked as a journeyman in several offices till Jan. 1, 1833, when he commenced business on his own account, with Francis V. Story as his partner. They printed the "Morning Post," the first penny daily ever published, which was owned and edited by Dr. H. D. Shepard. Story was drowned in July, 1833, and his place in the establishment was taken by Jonas Winchester. On March 22, 1834, the new firm issued the first number of "The New Yorker," a weekly folio (afterward changed to double quarto), devoted mainly to current literature, but giving also a summary of news, which soon became celebrated for the accuracy of its political statistics. Mr. Greeley was the editor. The paper reached a circulation of 9,000, and was continued seven years, but was never profitable. While engaged upon it Mr. Greeley wrote the leading articles for the "Daily Whig," and also edited for one year, 1838-'9, the "Jeffersonian," a political weekly published at Albany. In 1840 he edited and published the "Log Cabin," a campaign weekly devoted to the advocacy of Harrison's election to the presidency, which attained a circulation of 80,000 copies. On April 10, 1841, he issued the first number of the "Daily Tribune," which he says was "a small sheet, for it was to be retailed for a cent." Mr. Greeley was at first sole proprietor and publisher, as well as chief editor; but he soon formed a partnership with Thomas McElrath, who took charge of the business department. The "Daily Tribune" started with 500 subscribers, and of the first issue 5,000 copies were printed and sold or given away. In the autumn of 1841 the "Weekly Tribune" was commenced, the "New Yorker" and "Log Cabin" being merged in it. With these journals Greeley was closely identified during the remainder of his life, so that in the popular mind "Tribune" and "Horace Greeley" were interchangeable

terms; and of his work as a journalist and his influence on the rising profession of journalism he was confessedly and justly proud. In his autobiography he writes: "Fame is a vapor; popularity an accident; riches take wings; the only earthly certainty is oblivion; no man can foresee what a day may bring forth, while those who cheer to-day will often curse to-morrow: and yet I cherish the hope that the journal I projected and established will live and flourish long after I shall have mouldered into forgotten dust, being guided by a larger wisdom, a more unerring sagacity to discern the right, though not by a more unflinching readiness to embrace and defend it at whatever personal cost; and that the stone which covers my ashes may bear to future eyes the still intelligible inscription, 'Founder of the New York Tribune.'" In 1848 he was elected to congress to fill a vacancy, and served from Dec. 1 of that year till March 4, 1849, distinguishing himself by exposing and denouncing the abuses of the mileage system, but mainly through the columns of his journal, rather than from his place on the floor of the house. He was a warm advocate of industrial and social reforms, and was personally interested in the "North American Phalanx" (1843-'50), a socialist experiment near Red Bank, N. J., partly based upon the principles of Fourier. He labored zealously for the welfare of the poorer classes, and was a life-long opponent of slavery. Besides being continually busy with his editorial duties, he delivered numerous lectures and addresses at agricultural fairs, and occasional political speeches. His favorite topics were popular education, temperance, and labor organization. In 1851 he visited Europe, was a jurymen at the London crystal palace exhibition, and travelled rapidly through France, Italy, and Great Britain. In 1855 he made a second trip to Europe, spending six weeks in Paris. There he passed two days in prison, on the action of an obscure French sculptor, who claimed \$2,500 for damages to a statue which had been injured at the New York world's fair of 1853, of which Mr. Greeley was a director. He spent the winter of 1855-'6 in Washington, watching the memorable contest for the speakership and commenting on it in his letters to the "Tribune." For certain strictures on a resolution introduced by Albert Rust of Arkansas he was brutally assaulted by the latter in the capitol grounds, and was confined for several days by his injuries. In 1859 he visited California by the overland route, had public receptions in San Francisco and elsewhere, and addressed various assemblies on the Pacific railroad, political questions, &c. In 1860 he attended the republican national convention at Chicago, where he was largely instrumental in defeating the nomination of William H. Seward for president and securing that of Abraham Lincoln, though his preference was for Edward Bates of Missouri. This action was attributed to a personal feeling

of resentment on the part of Greeley, which is explained by the following extracts from a letter dated Nov. 11, 1854, which he addressed privately to Mr. Seward, but demanded for publication when it was referred to by the latter's friends during the canvass of 1860: "The election is over, and its results sufficiently ascertained. It seems to me a fitting time to announce to you the dissolution of the political firm of Seward, Weed, and Greeley, by the withdrawal of the junior partner, said withdrawal to take effect on the morning after the first Tuesday in February next. . . . I was a poor young printer and editor of a literary journal—a very active and bitter whig in a small way, but not seeking to be known out of my own ward committee—when, after the great political revulsion of 1837, I was one day called to the City hotel, where two strangers introduced themselves as Thurlow Weed and Lewis Benedict of Albany. They told me that a cheap campaign paper of a peculiar stamp at Albany had been resolved on, and that I had been selected to edit it. . . . I did the work required, to the best of my ability. It was work that made no figure, and created no sensation; but I loved it, and I did it well. When it was done, you were governor, dispensing offices worth \$3,000 to \$20,000 per year to your friends and compatriots, and I returned to my garret and my crust, and my desperate battle with pecuniary obligations heaped upon me by bad partners in business and the disastrous events of 1837. I believe it did not then occur to me that some one of these abundant places might have been offered to me without injustice; I now think it should have occurred to you. . . . In the Harrison campaign of 1840 I was again designated to edit a campaign paper. I published it as well, and ought to have made something by it, in spite of its extremely low price; my extreme poverty was the main reason why I did not. . . . Now came the great scramble of the swell mob of coon minstrels and cider-suckers at Washington, I not being counted in. . . . I asked nothing, expected nothing; but you, Governor Seward, ought to have asked that I be postmaster of New York." In the beginning of the civil war Greeley declared himself in favor of allowing the southern states to secede from the Union, provided a majority of their citizens voted in favor of that course. When hostilities were actually commenced, he demanded their vigorous prosecution, and was popularly held responsible for the "On to Richmond" cry, first uttered in the "Tribune," which preceded the defeat of Bull Run. In 1864, with the unofficial sanction of President Lincoln, he went to Clifton, Canada, to confer with George N. Sanders, Jacob Thompson, and Beverly Tucker, on the subject of peace. In that year also he was a presidential elector, and a delegate to the Philadelphia convention. At the close of the war he advocated a policy of universal amnesty with universal suffrage. In May, 1867,

he signed the bail bond of Jefferson Davis, thereby incurring so much popular censure at the north that the sale of his "History of the American Conflict," which had been very large on the publication of the first volume, suddenly stopped almost entirely on the second, then just issued. In 1869 he was the republican candidate for comptroller of the state of New York, but was defeated, though he received a larger vote than any other candidate on the ticket except Gen. Sigel. In 1870 he was a candidate for congress in the 6th New York district, and ran 300 votes ahead of the state ticket, but was defeated by the democratic candidate, S. S. Cox. Early in 1872 he made a journey to Texas, nominally for the purpose of delivering an address at the state agricultural fair and observing the industrial and commercial condition and prospects of the states he traversed; but probably the visit had also its political bearings, and he stopped at numerous places to make speeches and hold conferences with prominent citizens. On May 1 of that year a convention of so-called liberal republicans, who were dissatisfied with the administration, met at Cincinnati, and on the sixth ballot Mr. Greeley was nominated for president, B. Gratz Brown of Missouri being subsequently nominated for vice president. The democratic convention, which met at Baltimore in July, adopted these candidates and their platform. Mr. Greeley accepted the nomination, retired from the editorship of the "Tribune," and entered the canvass personally, travelling and speaking almost constantly till within a short time of the election. He received in the election 2,834,079 votes, against 3,597,070 for Grant, and carried the states of Georgia, Kentucky, Maryland, Missouri, Tennessee, and Texas. His powers of endurance had been strained to the utmost in the canvass, which was unusually exciting, and in which his foibles, his personal habits, and his anomalous political position were unsparingly caricatured and ridiculed. During the last month of it he was watching by the bedside of his wife, who died a few days before the election. Shortly after, he was prostrated by a disorder of the brain and sank rapidly. His funeral, though simple, was perhaps the most impressive ever witnessed in New York. The body lay in state in the city hall, through which an unbroken stream of visitors passed for an entire day; and the funeral services were attended by the president and vice president of the United States, the vice president elect, the chief justice, and many other eminent citizens from distant places. He died with a full belief in the doctrines of Universalism, which he had held for many years.—About the year 1852 Mr. Greeley purchased a farm of 50 acres, afterward enlarged to 75, on the Harlem railroad, in the township of New Castle, Westchester co., 35 m. N. of New York. The railroad station there was known as Chappaqua, from the Indian name of a mill stream which ran

through the place. Here for the last 20 years of his life he spent his Saturdays, working about the farm, his especial delight being in the woodland. His farming was not profitable, and was the subject of innumerable jests, all of which he took in good part, replying that he was only a farmer by proxy, and therefore did not expect to make money by it.—Mr. Greeley's published volumes are as follows: "Hints toward Reforms," consisting mainly of lectures and addresses (New York, 1850); "Glances at Europe" (1851); "History of the Struggle for Slavery Extension" (1856); "Overland Journey to San Francisco" (1860); "The American Conflict" (2 vols., Hartford, 1864-'6); "Recollections of a Busy Life" (New York, 1868); "Essays designed to elucidate the Science of Political Economy" (Boston, 1870); and "What I Know of Farming" (New York, 1871). His life has been written by James Parton (New York, 1855; new ed., 1868), and by L. U. Reavis (1872). See also "A Memorial of Horace Greeley" (New York, 1873).

**GREEN.** See LIGHT, and PAINTS.

**GREEN. I.** A central county of Kentucky, intersected by Green river, which is navigable by steamboats, and drained by several small streams; area, 525 sq. m.; pop. in 1870, 9,379, of whom 1,937 were colored. It contains much excellent limestone and a number of salt springs. The surface is undulating and hilly. The chief productions in 1870 were 34,098 bushels of wheat, 281,827 of Indian corn, 47,231 of oats, 87,222 lbs. of butter, and 1,375,091 of tobacco. There were 2,540 horses, 1,869 milch cows, 2,245 other cattle, 8,925 sheep, and 15,190 swine. Capital, Greensburg. **II.** A S. county of Wisconsin, bordering on Illinois, intersected by Pekatonica and Sugar rivers, the latter of which is a valuable mill stream; area, 576 sq. m.; pop. in 1870, 23,611. The surface is much diversified, the S. part consisting of prairies and the remainder being thinly wooded. The soil is very fertile. Limestone is abundant, and lead is mined. A branch of the Milwaukee and St. Paul railroad extends from Janesville to Monroe. The chief productions in 1870 were 541,859 bushels of wheat, 25,469 of rye, 947,105 of Indian corn, 743,019 of oats, 184,195 of potatoes, 909,485 lbs. of butter, 358,830 of cheese, 139,110 of wool, and 43,229 tons of hay. There were 9,744 horses, 11,474 milch cows, 15,506 other cattle, 39,477 sheep, and 35,879 swine; 2 manufactories of boots and shoes, 20 of carriages and wagons, 11 of clothing, 4 of barrels and casks, 4 of furniture, 12 of saddlery and harness, 3 of sashes, 11 of tin, copper, and sheet-iron ware, 6 of cigars, 2 of woollen goods, 2 flour mills, 10 saw mills, and 3 breweries. Capital, Monroe.

**GREEN, Ashbel,** an American clergyman, born at Hanover, N. J., July 6, 1762, died in Philadelphia, May 19, 1848. He graduated at the college of New Jersey in 1783, and was tutor and professor of mathematics and natural philosophy there till licensed to preach in 1786;

was ordained as colleague pastor of the second Presbyterian church in Philadelphia in May, 1787, and became pastor on the death of Dr. Sproat in 1793. He was chaplain of congress from 1792 to 1800. In 1809 he had a primary agency in forming the Philadelphia Bible society. He was one of the originators and most efficient friends of the theological seminary at Princeton. In 1812 he became president of Princeton college, but resigned in 1822 and returned to Philadelphia, where during the next 12 years he edited the monthly "Christian Advocate." He also preached to an African congregation for two years and a half, and rendered many important services in aid of the general interests of the church. Dr. Green was a clear, bold, and effective preacher, and an able college president. He was for nearly half a century one of the leading men of the Presbyterian church. He published a "Discourse delivered in the College of New Jersey, with a History of the College" (Boston, 1822); a "History of Presbyterian Missions," "Lectures on the Shorter Catechism" (2 vols.); 11 discourses, and various addresses, reports, &c.

**GREEN, Horace,** an American physician, born at Chittenden, Vt., Dec. 24, 1802, died at Sing Sing, N. Y., Nov. 29, 1866. He graduated in medicine at Middlebury, Vt., in 1824, and practised in Rutland till 1835, when he removed to New York. From 1840 to 1843 he was professor of the theory and practice of medicine in the medical college at Castleton, Vt., and in 1850 he accepted the same chair in the New York medical college, which he had that year assisted in founding. He resigned his professorship in 1860. In 1854 he and his colleagues established the "American Medical Monthly," of which he became one of the editors. Dr. Green was noted for his treatment of diseases of the throat and air passages by topical medication with nitrate of silver in solution. He published "Diseases of the Air Passages" (New York, 1846); "Pathology and Treatment of the Croup" (1849); "Surgical Treatment of the Polypi of the Larynx and the Edema of the Glottis" (1852); "Report of 106 Cases of Pulmonary Diseases treated by Injections into the Bronchial Tubes with a Solution of Nitrate of Silver" (1856); "Selections from the Favorite Prescriptions of Living American Physicians" (1858); and "Pulmonary Tuberculosis" (1864).

**GREEN, Jacob,** an American author, born in Philadelphia, July 26, 1790, died there, Feb. 1, 1841. He graduated at the university of Pennsylvania at the age of 16, and immediately afterward published in connection with a young friend a treatise on electricity and galvanism. He was admitted to the bar, but never practised, and in 1818 was appointed professor of chemistry, experimental philosophy, and natural history in the college of New Jersey. This position he exchanged four years later for the chair of chemistry in the Jefferson medical college, Philadelphia, which he filled until his

death. He was the author of "Chemical Philosophy" (Philadelphia, 1829), "Astronomical Recreations," "Treatise of Electro-Magnetism," "Monograph of the Trilobites of North America," &c.; of papers in the "American Journal of Science;" and of "Notes of a Traveller through England and Europe" (1831).

**GREEN, John Richard.** See supplement.

**GREEN, Samuel,** an American printer, born in England in 1615, died in Cambridge, Mass., Jan. 1, 1702. He succeeded Day in the printing house at Cambridge about 1648. He printed the "Cambridge Platform" in 1649, the laws in 1660, and, in the Indian language, the Psalter, Eliot's Catechism, Baxter's "Call to the Unconverted," the New Testament, and 1,000 copies of the Bible in 1683. He had 19 children, and his descendants were a race of printers, living in Massachusetts, Connecticut, Vermont, and Maryland.

**GREEN, Seth,** an American fish culturist, born in Rochester, N. Y., March 19, 1817. A fisherman by occupation, his attention was early attracted by the gradual diminution of fish in the waters of the state, and in 1838 he began to devote himself to practical fish culture. In 1864 he organized the fish-breeding establishment at Caledonia springs in Livingston co., which he managed with great success for four years. In 1867 he invented a shad-hatching box, which has been extensively used in stocking the Connecticut, Hudson, and other rivers. He published a work on "Trout Culture" in 1870, and in 1871 succeeded in transporting 10,000 young shad from the Hudson to the Sacramento. He was for some years commissioner of fisheries of the state of New York, and is now (1874) superintendent of the state hatching house at Caledonia. He has been justly styled the father of American fish culture.

**GREEN, William Mercer,** an American bishop of the Protestant Episcopal church, born in Wilmington, N. C., May 2, 1798. He graduated at the university of his native state in 1818, studied for the ministry, and was ordained in 1820. He was appointed professor of rhetoric in the university of North Carolina in 1837, and was elected first bishop of Mississippi in 1849, and consecrated Feb. 24, 1850. Bishop Green was among the founders of the "University of the South," at Suwanee, Tenn., in 1858, and became its chancellor in 1866, which post he still occupies (1874). He has published a "Memoir of Bishop Ravenscroft," and "Sermons on Apostolic Succession and Baptismal Regeneration."

**GREEN BAY,** a large arm of Lake Michigan, communicating with the W. side of the lake by a broad opening at which lies a group of islands. It partly separates Wisconsin from the upper peninsula of Michigan, and is 100 m. long from N. E. to S. W., and from 15 to 30 m. broad. It receives Menomonee, Fox, and several smaller rivers. The name Green was given it on account of its color, caused by its great depth, which is said to exceed 500 ft.

**GREEN BAY,** a city and the capital of Brown co., Wisconsin, on a low peninsula between Fox and East rivers, about 2 m. above the head of Green bay, 100 m. N. of Milwaukee; pop. in 1860, 2,275; in 1870, 4,666. It has a fine harbor, accessible by the largest steamers from Lake Michigan; while, by means of the improvements on Fox river and the canal across the portage, boats of 5 ft. draught have passed, during high water, by way of the Fox and Wisconsin rivers, from Lake Michigan to the Mississippi. The Wisconsin division of the Chicago and Northwestern railroad passes through Fort Howard (pop. in 1870, 2,462), a borough on the W. bank of the Fox opposite Green Bay, with which it is connected by a bridge and ferries. Green Bay itself is the terminus of the Milwaukee and Northern and the Green Bay and Lake Pepin railroads. The most important item of trade is lumber, about 79,000,000 feet, besides 200,000,000 shingles and 6,000,000 staves, the product of 40 or 50 mills in the surrounding country, being marketed here annually. The grain and flour trade is also considerable. The receipts in 1871, including Fort Howard, amounted to 539,102 bushels of grain and 110,000 barrels of flour. To accommodate this traffic, an elevator with a capacity of 225,000 bushels has been erected upon a pier which projects 800 ft. into the river, and along which the railroad tracks have been extended. The entire trade of the city in 1871 amounted to about \$3,500,000. It contains a number of noteworthy public buildings, including large warehouses, an elegant court house, and a well arranged opera house, and has many handsome residences. There are three national banks with an aggregate capital of \$200,000, 12 public schools, including a high school, a daily and three weekly (one German) newspapers, and 11 churches.—The first permanent settlement at Green Bay was effected by the French in 1745. A portion of the site was laid out about 1830 under the name of Navarino, and another portion in 1835 under that of Astor. They were incorporated as Green Bay in 1839, and in 1854 a city charter was granted. In the early part of this century it was a post of the American fur company.

**GREENBRIER,** a S. E. county of West Virginia, bordering on Virginia, intersected by Greenbrier river, a N. E. affluent of the Great Kanawha or New river, and bounded S. E. by a ridge of the Alleghanies; area, 880 sq. m.; pop. in 1870, 11,417, of whom 1,103 were colored. The soil of the valleys is fertile. The celebrated White Sulphur Springs are in this county, which is crossed by the Chesapeake and Ohio railroad. The chief productions in 1870 were 50,214 bushels of wheat, 181,381 of Indian corn, 92,295 of oats, 13,928 of potatoes, 174,865 lbs. of butter, 34,051 of wool, and 7,444 tons of hay. There were 2,805 horses, 3,201 milch cows, 6,199 other cattle, 13,880 sheep, and 5,733 swine; 4 saw mills, and 2 woollen factories. Capital, Lewisburg.

**GREENBUSH**, a town of Rensselaer co., New York, on the E. bank of the Hudson, opposite Albany, with which it is connected by two bridges; pop. in 1870, 6,202. It is the S. terminus of the Troy and Greenbush railroad, and is intersected by the Boston and Albany and the Hudson River lines. The depot of the latter is at a point locally known as East Albany. The town contains two saw mills, flour mills, a blast furnace, &c. It was incorporated in 1795, and in 1855 East Greenbush and North Greenbush were separated from it.

**GREENCEASTLE**, a city and the capital of Putnam co., Indiana, 1 m. E. of Walnut fork of Eel river, at the intersection of the Louisville, New Albany, and Chicago railroad with the St. Louis, Vandalia, Terre Haute, and Indianapolis, and the Indianapolis and St. Louis lines, 40 m. W. by S. of Indianapolis; pop. in 1870, 3,227. It is pleasantly situated on a high table land, and is the commercial centre of a rich farming and extensive stock-raising region. It contains a court house, a jail, a national bank, a large rolling mill and nail factory, seven public schools, including a high school, and several churches, and has two weekly newspapers. Indiana Asbury university (Methodist), situated here, was organized in 1835, and in 1874 had 10 professors and instructors, and 439 students, of whom 245, including 38 females, were of the collegiate grade. The Whitcomb and the college circulating libraries contain 9,000 volumes. There is also in the city a Presbyterian female college, having 5 instructors and 120 students.

**GREENE**, the name of counties in 14 of the United States. **I.** A S. E. county of New York, bounded E. by the Hudson river, and drained by Catskill creek and Schoharie river; area, 600 sq. m.; pop. in 1870, 31,832. The surface is broken by the Catskill mountains, which are mostly sterile. The valleys and level districts of the N. E. contain some excellent soil. A branch of the New York Central railroad from Schenectady terminates at Athens in this county. The chief productions in 1870 were 72,016 bushels of rye, 138,889 of Indian corn, 378,422 of oats, 97,947 of buckwheat, 276,787 of potatoes, 1,538,203 lbs. of butter, 52,147 of wool, and 103,357 tons of hay. There were 5,902 horses, 14,825 milch cows, 10,791 other cattle, 12,778 sheep, and 6,276 swine; 10 manufactories of carriages, 10 of bricks, 6 of barrels and casks, 1 of cotton goods, 8 of furniture, 5 of iron castings, 2 of machinery, 2 of paper, 9 of saddlery and harness, 4 of woollen goods, 5 ship yards, 4 saw mills, 7 flour mills, and 4 tanneries. Capital, Catskill. **II.** A S. W. county of Pennsylvania, bounded S. and W. by West Virginia and E. by the Monongahela, and watered by several small streams; area, 600 sq. m.; pop. in 1870, 25,887. It has a hilly surface and a fertile soil, and abounds in bituminous coal. The chief productions in 1870 were 255,584 bushels of wheat, 26,606 of rye, 749,520 of Indian corn,

438,222 of oats, 53,712 of potatoes, 759,135 lbs. of butter, 444,489 of wool, and 23,206 tons of hay. There were 7,278 horses, 7,369 milch cows, 15,380 other cattle, 121,135 sheep, and 19,580 swine; 7 manufactories of carriages, 6 of barrels and casks, 8 of furniture, 14 of saddlery and harness, 4 of stone and earthenware, 3 of woollen goods, 4 flour and 4 saw mills, 8 tanneries, and 6 currying establishments. Capital, Waynesburg.

**III.** A central county of Virginia, lying partly on the S. E. slope of the Blue Ridge, and bounded N. E. by Rapidan river; area, 230 sq. m.; pop. in 1870, 4,634, of whom 1,452 were colored. It has an uneven surface, traversed by some fertile valleys. The chief productions in 1870 were 36,060 bushels of wheat, 84,033 of Indian corn, 37,886 of oats, and 262,030 lbs. of tobacco. There were 1,046 horses, 885 milch cows, 1,221 other cattle, and 3,466 swine. Capital, Stanardsville. **IV.** An E. county of North Carolina, drained by the Mackoson, an affluent of the Neuse river; area, about 280 sq. m.; pop. in 1870, 8,687, of whom 4,521 were colored. The surface is level and the soil fertile. Marl is found in several places. The chief productions in 1870 were 223,988 bushels of Indian corn, 23,521 of peas and beans, 44,531 of sweet potatoes, and 6,268 bales of cotton. There were 779 horses, 982 milch cows, 2,225 other cattle, and 9,657 swine. Capital, Snow Hill. **V.** A N. E. central county of Georgia, bounded S. W. by the Appalachee and Oconee rivers, the latter of which intersects the N. W. part; area, 374 sq. m.; pop. in 1870, 12,454, of whom 8,156 were colored. It is intersected by the Georgia and Athens branch railroads. It has a hilly surface, and the soil, though originally fertile, is partly worn out. The chief productions in 1870 were 24,651 bushels of wheat, 132,635 of Indian corn, 9,735 of oats, 13,971 of sweet potatoes, 63,020 lbs. of butter, and 5,699 bales of cotton. There were 829 horses, 993 mules and asses, 1,384 milch cows, 2,651 other cattle, 2,240 sheep, and 5,100 swine; 3 carriage factories, 1 cotton factory, and 6 flour mills. Capital, Greensborough. **VI.** A W. county of Alabama, bounded S. E. by Black Warrior river and S. W. by the Tombigbee, the two streams uniting at the S. W. extremity of the county, and being navigable by steamboats during half the year; area, about 750 sq. m.; pop. in 1870, 18,399, of whom 14,541 were colored. The surface is moderately uneven; the soil is fertile. The chief productions in 1870 were 207,782 bushels of Indian corn, 22,080 of sweet potatoes, and 9,910 bales of cotton. There were 1,077 horses, 2,101 mules and asses, 2,145 milch cows, 3,459 other cattle, 2,576 sheep, and 6,674 swine. Capital, Eutaw. **VII.** A S. E. county of Mississippi, bordering on Alabama, drained by Chickasawha and Leaf rivers, which unite in the S. part to form the Pascagoula; area, 830 sq. m.; pop. in 1870, 2,038, of whom 372 were colored. It has an undulating surface, a soil only moderately fertile, and pine

forests. The Mobile and Ohio railroad touches the N. E. corner. The chief productions in 1870 were 21,473 bushels of Indian corn, and 13,877 of sweet potatoes. There were 400 horses, 2,402 milch cows, 3,777 other cattle, 4,357 sheep, and 7,338 swine. Capital, Leakesville. **VIII.** A N. E. county of Arkansas, bounded N. by Missouri, and separated from it on the E. by St. Francis river, and bordered S. W. by the Cache river; area, 950 sq. m.; pop. in 1870, 7,573, of whom 156 were colored. The surface is level, and the soil of the river bottoms fertile. The chief productions in 1870 were 10,890 bushels of wheat, 208,352 of Indian corn, 10,623 of oats, 12,904 of sweet and 7,691 of Irish potatoes, and 983 bales of cotton. There were 1,173 horses, 1,305 milch cows, 2,852 other cattle, 2,727 sheep, and 8,232 swine. Capital, Gainesville. **IX.** A N. E. county of Tennessee, bordering on North Carolina, and traversed by Noli-chucky river; area, 750 sq. m.; pop. in 1870, 21,688, of whom 2,064 were colored. It contains valuable beds of iron ore. The surface is elevated, uneven, and well timbered. It is traversed by the East Tennessee, Virginia, and Georgia, and the Cincinnati, Cumberland Gap, and Charleston railroads. The chief productions in 1870 were 238,716 bushels of wheat, 496,659 of Indian corn, 149,518 of oats, 21,296 of Irish and 11,331 of sweet potatoes, 268,411 lbs. of butter, and 7,124 tons of hay. There were 4,644 horses, 5,279 milch cows, 8,008 other cattle, 21,130 sheep, and 25,306 swine; 2 blast furnaces, 3 flour and 5 saw mills, 10 tanneries, and 7 currying establishments. Capital, Greeneville. **X.** A S. W. county of Ohio, watered by Mad and Little Miami rivers; area, 432 sq. m.; pop. in 1870, 28,038. It contains limestone and variegated marble. The surface is undulating, and the soil consists of fertile clay. It is traversed by the Little Miami railroad, the Dayton, Xenia, and Western, and the Springfield branch, which connect at Xenia, the Atlantic and Great Western, and the Cincinnati, Sandusky, and Cleveland railroads. Antioch college is at Yellow Springs in this county. The chief productions in 1870 were 643,980 bushels of wheat, 10,674 of rye, 1,527,647 of Indian corn, 152,747 of oats, 22,491 of barley, 83,270 of potatoes, 370,179 lbs. of butter, 109,591 of wool, 277,360 of tobacco, 14,283 tons of hay, 1,137,675 lbs. of flax, and 38,998 bushels of flax seed. There were 7,585 horses, 5,741 milch cows, 8,695 other cattle, 29,320 sheep, and 3,395 swine; 2 manufactories of bagging, 8 of bricks, 21 of carriages, 21 of clothing, 2 of barrels and casks, 1 of cordage and twine, 1 of gunpowder, 3 of linseed oil, 5 bakeries, 11 flour mills, 1 tannery, 1 currying establishment, 1 distillery, and 8 saw mills. Capital, Xenia. **XI.** A S. W. county of Indiana, drained by the W. fork of White river; area, 540 sq. m.; pop. in 1870, 19,541. It is diversified by prairies, oak openings, and forests, and has a rich soil. The Indianapolis and Vin-

cennes railroad and the Wabash and Erie canal pass through it. The chief productions in 1870 were 190,647 bushels of wheat, 784,195 of Indian corn, 101,410 of oats, 39,639 of potatoes, 160,958 lbs. of butter, 79,319 of wool, 112,242 of tobacco, and 7,833 tons of hay. There were 6,464 horses, 4,530 milch cows, 8,132 other cattle, 30,341 sheep, and 26,195 swine; 5 flour mills, 11 saw mills, and 1 distillery. Capital, Bloomfield. **XII.** A W. county of Illinois, bounded W. by the Illinois river; area, 500 sq. m.; pop. in 1870, 20,277. It has a rolling surface and a fertile soil, and contains an abundance of anthracite coal and timber. It is traversed by the Chicago and Alton railroad (Jacksonville division), and the Rockford, Rock Island, and St. Louis railroad. The chief productions in 1870 were 577,400 bushels of wheat, 1,051,313 of Indian corn, 64,029 of oats, 50,435 of potatoes, 195,992 lbs. of butter, 70,854 of wool, and 20,081 tons of hay. There were 9,034 horses, 4,479 milch cows, 13,146 other cattle, 13,690 sheep, and 31,690 swine; 12 manufactories of carriages and wagons, 6 of saddlery and harness, 3 of stone and earthen ware, 1 of woollen goods, 5 of bricks, 4 saw and 5 flour mills. Capital, Carrollton. **XIII.** A W. central county of Iowa, intersected by Raccoon river; area, 600 sq. m.; pop. in 1870, 4,627. It consists mostly of prairies. It is traversed by the Chicago and North-western and the Des Moines Valley railroads. The chief productions in 1870 were 98,943 bushels of wheat, 226,965 of Indian corn, 54,967 of oats, 18,951 of potatoes, and 6,862 tons of hay. There were 1,774 horses, 1,300 milch cows, 2,966 other cattle, 3,875 sheep, and 5,852 swine; 1 flour mill, and 4 saw mills. Capital, Jefferson. **XIV.** A S. W. county of Missouri, drained by branches of the Osage and White rivers; area, 750 sq. m.; pop. in 1870, 21,549, of whom 2,156 were colored. The surface is diversified and occupied by alternate forests and prairies. Limestone and lead are found. The soil is fertile. It is traversed by the Atlantic and Pacific railroad. The chief productions in 1870 were 171,166 bushels of wheat, 859,953 of Indian corn, 256,096 of oats, 47,626 of potatoes, 159,245 lbs. of butter, 37,491 of wool, and 4,487 tons of hay. There were 6,752 horses, 4,661 milch cows, 7,940 other cattle, 22,492 sheep, and 29,542 swine; 3 manufactories of agricultural implements, 3 of bricks, 1 of iron castings, 3 of carriages, 1 of engines and boilers, 2 of saddlery and harness, 2 of tobacco and snuff, 5 flour mills, 1 distillery, 1 planing mill, and 7 saw mills. Capital, Springfield.

**GREENE, Christopher**, an American soldier, born in Warwick, R. I., in 1737, killed near the Croton river, Westchester co., N. Y., May 13, 1781. He was among the first to take the field on the patriotic side after the engagements at Lexington and Concord. He served in the campaign in Canada under Arnold, and subsequently under Montgomery with the rank

of colonel, and was taken prisoner in the attack on Quebec, Dec. 31, 1775. On Oct. 22, 1777, while in command of Fort Mercer at Red Bank, on the Delaware, he sustained an attack from a large force of Hessians under Col. Donop, who were repulsed with great slaughter. For these services a sword was voted him by congress, which was presented in 1786 to his son, and a monument commemorative of the battle was erected in the neighborhood of Fort Mercer in 1829. Col. Greene lost his life in an encounter with a superior body of tory dragoons who had surprised his post. He killed several of the enemy with his own hand, but was finally overpowered.

**GREENE, George Washington**, an American author, born in East Greenwich, R. I., April 8, 1811. He is a grandson of Nathanael Greene, the revolutionary general. He was obliged by ill health to leave Brown university in his junior year in 1827, and resided from that time in Europe, with the exception of a few short visits home, till 1847. From 1837 to 1845 he was United States consul at Rome. Between 1835 and 1850 he published a series of essays in the "North American Review," which were collected in a volume entitled "Historical Studies" (New York, 1850). On his return to the United States he became instructor in modern languages in Brown university, and edited several text books, among which were a new edition of Pütz and Arnold's "Ancient Geography and History" (New York, 1849) and a "History and Geography of the Middle Ages" (1851). He furnished the life of Gen. Greene in Sparks's "American Biography," and afterward published separately a "Life of Nathanael Greene" (2 vols. 8vo, New York, 1867-'8). In 1860 he published a volume of "Biographical Studies;" in 1865 a "Historical View of the American Revolution;" and in 1866 a criticism of the account of Gen. Greene in Baneroff's history. In 1872 he was appointed non-resident professor of American history in Cornell university.

**GREENE, Nathanael**, an American soldier, born at Potowhommet, Warwick co., R. I., May 27, 1742, died near Savannah, Ga., June 19, 1786. His father had a farm and a forge, and was a leading preacher among the Quakers. Nathanael was trained to manual labor, but picked up more than ordinary knowledge of history, geometry, law, and moral and political science. In 1770 he was chosen a member of the general assembly for Coventry, whither he had removed to take charge of another forge; and from that time he took an active part in public affairs till the close of the war. He was the first to establish a public school in Coventry, and for engaging in military exercises was expelled from the society of Friends. In 1774 he joined the Kentish guards as a private. In July of the same year he married Catharine Littlefield of Block island, and in May, 1775, was appointed by the general assembly to command as brigadier general the Rhode Island contingent in

the army before Boston. He joined his command at Roxbury on June 3, and from that time remained in active service without a day's furlough till the final disbandment of the army in 1783. At Boston his brigade was distinguished by its discipline, and he won the love and confidence of Washington from the beginning of their intercourse. After the evacuation of Boston he was intrusted with the defence of Long Island, but was stricken down by a fever a few days before the battle there. In September, 1776, he was made major general, and appointed to the command in New Jersey. At Trenton he led the division with which Washington marched in person, and with Knox was for following up the advantages of that brilliant surprise by advancing directly upon the other detachments of the enemy. He took an equal part in the battle of Princeton. At the Brandywine he commanded a division, and by a rapid march and successful stand preserved the army from destruction. At Germantown he commanded the left wing which penetrated into the village. On March 2, 1778, he accepted, at the urgent solicitation of Washington and the committee of congress, the office of quartermaster general, stipulating that he should retain his right to command in action. He held this position until August, 1780. At Monmouth, in 1778, he commanded the right wing. He took an active part in the attempt upon Newport, commanding the right wing in the battle of Tiverton heights. On June 23, 1780, he checked with two brigades and a small body of militia the advance of a corps of 5,000 of the enemy, in the brilliant battle of Springfield. He was in command of the army during Gen. Washington's visit to Hartford in September, 1780, when Arnold's conspiracy was discovered, and sat as president of the court of inquiry upon Major André. On Oct. 14 of the same year he was appointed to the command of the southern army, which he found on his arrival, Dec. 2, in a state of utter disorganization and want. On the 20th he advanced to a well-chosen camp on the banks of the Pedee, and began a series of operations which in less than a year stripped the enemy of nearly all their hard-won conquests in the Carolinas and Georgia, and shut them up in Charleston and its immediate neighborhood. The events of this year were the battle of the Cowpens, won by Gen. Morgan at the opening of the campaign; a brilliant retreat from the Catawba to the Dan; the return into North Carolina, in which Gen. Greene maintained his position for two weeks within striking distance of a superior enemy, in such a manner as both to avoid an engagement and cover the roads by which his reinforcements were coming; the battle of Guilford Court House, in which he lost the field, but gained the end for which he fought; the pursuit of Cornwallis to the Deep river; the daring advance into South Carolina; the battle of Hobkirk's hill, a second defeat followed by the results of victory; the

siege of Fort Ninety-six, raised by the advance of Lord Rawdon, but followed by the immediate evacuation of the post and the retreat of the enemy toward the west; the drawn battle of Eutaw Springs, the hardest fought field of the revolution; and the advance upon Dorchester, spoken of by Washington as "another proof of the singular abilities of" Gen. Greene. Congress presented him with a medal for the battle of Eutaw Springs, and two of the cannon taken from the enemy for his general services. The Carolinas and Georgia made him valuable grants of property. After passing a year in Rhode Island, he removed to Mulberry Grove on the Savannah river, where he died of sunstroke. A monument was voted by congress, but never erected, and all traces of his burial place have been lost. He left two sons and three daughters, and an estate seriously embarrassed by his efforts in 1783 to feed and clothe his army.

**GREENE, I. Nathaniel**, an American author, born in Boscawen, N. H., May 20, 1797, died in Boston, Nov. 29, 1877. At the age of 12 he entered a printing office in Concord, and at 15 became editor of the "Concord Gazette." Removing to Portsmouth in 1814, he edited for a year the "New Hampshire Gazette." From 1815 to 1817 he conducted the "Gazette" at Haverhill, Mass. He commenced the publication of the "Essex Patriot" at Haverhill in May, 1817, and conducted it for nearly four years, when he removed to Boston, and established, Feb. 6, 1821, the "Boston Statesman," which became the leading democratic journal of the state. In 1829, on the election of President Jackson, Mr. Greene was made postmaster of Boston, which office he held till 1841, and again from 1845 to 1849. In 1836 he translated a "History of Italy" from the Italian of Sforzozzi, which was followed by the translation of two volumes of "Tales from the German" (Boston, 1837). Six years later he published "Tales and Sketches from the French, German, and Italian." **H. Charles Gordon**, an American journalist, brother of the preceding, born in Boscawen, N. H., July 1, 1804. At an early age he was placed in the office of the "Essex Patriot" as an apprentice, whence he was removed to a printing office at Exeter. At 18 he went to Boston, and became connected with the "Statesman," his brother's journal. He conducted in 1825-'6 the "Free Press" at Taunton. Returning to Boston, he published a literary paper, the "Spectator," after which he resumed his connection with the "Statesman." In 1827 he removed to Philadelphia, where he was one of the conductors of the "National Palladium," the first Pennsylvania journal that advocated the election of Gen. Jackson to the presidency. In 1828 he was employed in the office of the "United States Telegraph," conducted by Gen. Duff Green, at Washington, then the principal journal of the democratic party. After the election of Jackson he succeeded

his brother Nathaniel as one of the proprietors and publishers of the "Statesman," of which he finally became sole proprietor. On Nov. 9, 1831, he issued the first number of the Boston "Morning Post." He has several times been a candidate for member of congress. He was naval officer at Boston from 1853 to 1857.

**GREENE, Robert**, an English dramatist and miscellaneous writer, born at Ipswich about 1560, died in London, Sept. 3, 1592. He was educated at Cambridge, and studied for a while also at Oxford. Although bred to a profession, he followed the career of an author, rivalling his brother dramatists, if not always in dramatic power, at least in profligacy. His life was spent alternately in plenty and penury. Being deserted by all his friends, he was indebted for shelter and attendance in his last sickness to a poor cobbler and his wife. He was a prolific writer, and in addition to his dramas, of which only five that are certainly his have come down to us, wrote poems, tales, and pamphlets. Some of his poems are characterized by much elegance of diction. His tale of "Pandosto, or the Historie of Dorastus and Faunia," furnished Shakespeare the plot for his "Winter's Tale." In "A Groat's Worth of Wit bought with a Million of Repentance," Greene alludes to Shakespeare as "an upstart crow beautified with our feathers—in his own conceit the only *shake-scene* in a country." An edition of his works was published by the Rev. A. Dyce in 1831 (2 vols. 8vo).

**GREENFIELD**, the shire town of Franklin co., Massachusetts, on the W. bank of the Connecticut river, 20 m. N. of Northampton, and 80 m. W. N. W. of Boston; pop. in 1870, 3,589. It is situated at the junction of the Vermont and Massachusetts with the Connecticut River railroad, and is connected with Albany and Troy by the Troy and Greenfield line, which passes through the Hoosac tunnel. It is supplied with water power by Green and Fall rivers, the latter of which forms part of the E. boundary. Besides the county buildings, it contains three manufactories of hardware for children's carriages, one of children's carriages, one of bolt-cutting machines, one of plumbs and levels, one of bench planes and ox shoes, a tannery, a carriage factory, and a sash and blind factory. The first manufactory of table cutlery in the United States was established here by John Russell in 1834, under the name of the Green River manufacturing company; destroyed by fire in 1836, it was rebuilt near Greenfield village, but within the limits of the town of Deerfield. The J. Russell manufacturing company of table cutlery was established in 1855; in 1870 its works were removed to Turner's Falls, a village on the E. bank of the Connecticut,  $2\frac{1}{2}$  m. from Greenfield, with which it is connected by a suspension bridge built in 1872. Greenfield contains two national banks with an aggregate capital of \$500,000, two savings banks with deposits amounting to \$3,500,000, four hotels, gas

works, water works, 10 public schools, including a high school, a young ladies' select school, a town library of 4,000 volumes, and seven churches, and has two weekly newspapers. The town was separated from Deerfield in 1753.

**GREENHEART**, a tree belonging to the laurel family and of the genus *nectandra*. Botanists do not agree as to the species, some calling it *N. Rodiei*, while others consider it a variety of *N. leucantha*. It is found in several of the West India islands and in various parts of South America, where it forms a large tree, often 50 or 60 ft. high and 2 or 3 ft. in diameter; the alternate polished leaves are from 4 to 9 in. long; the flowers, in loose panicles, consist of a wheel-shaped calyx, no petals, nine fertile stamens, and a single pistil; the divisions of the calyx fall away, and its tube remains as a small cup which supports the berry. The bark has been used as a substitute for cinchona, and, under the name of bibiru or bebeeru, has been somewhat employed in medicine. It contains an active principle called bebeerine, which is not to be confounded with berberine. The great value of the tree is in its timber, which is sent from Demerara to England, where from its hardness it is substituted in some cases for lignum vitæ; it is considered one of the most valuable timbers for ship building on account of its great strength and durability.

**GREENHOUSE**, a name commonly applied to any glass structure in which plants are raised, but by professional gardeners restricted to houses in which a comparatively cool temperature is maintained. A cool greenhouse is one intended simply to protect tender plants during the winter season, and the temperature may be as low as 35° or 40°; but plants are not expected to grow in such a house. Where flowers are desired, the day temperature must be at least 60°, with a minimum of 40° at night. Where a higher temperature than this is kept up, the house is called a stove, and is heated to 70° or 80° or more, according to the character of the plants it contains. A conservatory is a greenhouse attached to a dwelling, and is designed more for the effective display of plants than for raising them. Houses for special cultures are graperies, ferneries, orchard houses, orchid houses, &c. In designing a greenhouse, light, heat, air, and water have to be considered. The simplest form of a greenhouse is a "lean-to," in which the back is formed by its being placed against some other building, a fence or a wall erected for the purpose. The roof slopes at an angle of 45° from the back wall to the front one, which is usually provided with a row of lights between the bench upon which the plants are placed and the plate upon which the roof rests. The span-roofed house, being intended to receive light upon all sides, usually stands apart from other buildings; its roof is straight or curvilinear, and its height and other dimensions are governed by the kind of plants for which it

is intended; houses of this kind are frequently made ornamental by means of architectural embellishments. Large houses are often built with a central dome and span-roofed wings, and some are built with a half span, one portion of the roof being shorter than the other. In commercial establishments, where the greatest economy is studied and little regard is paid to appearances, the houses are usually low span-roofs. Sashes 6 ft. long are used for the roof; these meet above on a central ridge pole, and rest below on a plate which has its upper surface hollowed to form a water conductor. An excavation is made deep enough to allow head room beneath the glass, and walled up with brick to a foot or two above the surface of the ground. Such houses are about 11 ft. wide, with a bench 4 ft. wide upon each side and a central path of 3 ft. This brings the plants upon the benches near to the glass, the position most favorable to growth, and gives sufficient room to work in; as the plants are intended to be sold while small, less space is required than in houses for other purposes. Heating was formerly accomplished entirely by means of flues running the whole length of the house, crossing the end, and returning upon the other side, the furnace being in a pit and accessible from the outside. This method of heating is sometimes still employed, as the outlay is less than in any other plan. The flue is sometimes built of brick its whole length, or is of brick for a few feet nearest the furnace, while the remainder is of pipes of earthenware or cement. The disadvantages of flues are the danger from leaks which may allow injurious gases to escape, and the difficulty of heating all parts of the house equally. On these accounts heating by means of hot water is preferred. There are numerous styles of greenhouse boilers, but they are all built upon the same principle, viz.: a reservoir of water with a pipe beginning near its upper portion, running the whole length of the house, and returning to the boiler, which it enters near its lower part. When a fire is lighted under the boiler, the water immediately begins to circulate, the lighter warm water passing out by the upper outlet, through the pipe, and returning to it through the inlet. In its passage through the pipes it gives off its heat by radiation, and with a well constructed apparatus the heat will be evenly distributed. At the end of the house furthest from the boiler is the expansion tank, an upright iron cylinder of somewhat larger diameter than the heating pipes; the flow and return pipe are both connected with this, which is open at the top or loosely covered; this prevents the expansion of the water when heated from exerting any pressure upon the pipes, and allows the air liberated from the water to escape, as well as any steam that may be formed when the apparatus is working to its fullest capacity. There is much difference in the internal construction of the boilers, each inventor striving

to expose the greatest possible heating surface to the action of the fire. To economize heat, a flue to carry off the products of combustion from the boiler is sometimes run through the house. Ventilation is accomplished in various ways: in small houses by lifting or sliding the sashes, and in large ones by raising a portion of the upper part of the roof by proper machinery. A water cistern is generally built under the floor of the greenhouse, into which the water from the roof is conducted. Shading is required as spring approaches, which is commonly accomplished by washing the glass with ordinary lime wash, or with whiting and milk; in some cases a screen of muslin is used, or a lattice work of narrow strips of wood.—For the construction and management of commercial greenhouses, Henderson's "Practical Floriculture" may be consulted. "Choice Stove and Greenhouse Plants," by B. S. Williams, is one of the most recent English works; and the amateur will find useful hints in "The Greenhouse as a Winter Garden," by F. E. Field.

**GREEN LAKE**, a S. E. county of Wisconsin, intersected by Fox river; area, 360 sq. m.; pop. in 1870, 13,195. Green and Pacawa lakes, each about 9 m. long, are in the county. The surface is undulating and the soil productive. The chief productions in 1870 were 614,247 bushels of wheat, 17,702 of rye, 251,822 of Indian corn, 300,814 of oats, 18,416 of barley, 11,800 of buckwheat, 91,343 of potatoes, 362,598 lbs. of butter, 119,214 of wool, 32,551 of hops, and 29,628 tons of hay. There were 4,108 horses, 4,353 milch cows, 5,403 other cattle, 31,501 sheep, and 4,659 swine; 3 manufactories of boots and shoes, 15 of carriages, 3 of cheese, 5 of clothing, 3 of barrels and casks, 4 of furniture, 1 of woollen goods, 1 saw mill, and 10 flour mills. Capital, Dartford.

**GREENLAND** (Dan. and Ger. *Grönland*; Fr. *Groënland*), an extensive region belonging to Denmark, lying N. E. of the mainland of North America, from which and its outlying islands it is separated by Davis strait, Baffin bay, and the northward extensions of the latter, known as Smith sound, Kennedy channel, and Robeson strait; pop. in 1871, 9,825. Cape Farewell, its S. extremity, is a point on a small island, in lat. 59° 49' N., lon. 43° 54' W., from which the E. coast extends N. E. to Cape Brewster, lat. 70°, where it takes a more northerly course and stretches toward the pole to an unknown distance. The S. part of this coast is washed by the Greenland sea, a portion of the N. Atlantic, and the N. part by the Arctic ocean. Iceland, which is distant about 160 m., is separated from it by Denmark strait. The W. coast pursues a N. N. W. direction to Cape Alexander, its westernmost extremity, about lat. 78° 10', lon. 73° 30', where it turns N. E. and extends beyond lat. 82°. According to the report of two of the crew of the *Polaris*, it terminates about lat. 83°, and trends thence E., thus indicating the insularity of Greenland. A channel about 60 m. wide, running E. and

W., is said to have been seen on the north, and beyond it the lofty hills of a polar land. The E. coast is practically inaccessible on account of the drift ice, which, borne S. by the polar current, sometimes fills the entire sea between it and Iceland, and forms a barrier around Cape Farewell extending more than 100 m. seaward. The outline of this coast is rugged and barren, with cliffs and lofty precipices which are visible far out at sea. A number of inlets, the principal of which are Scoresby and Davy sounds, extend an unknown distance into the interior. Henry Hudson explored this coast in 1607, in an attempt to make the N. W. passage, and named a cape in lat. 73° 30' Hold with Hope. It was visited by Scoresby in 1822, Clavering and Sabine in 1823, Graah in 1829 and 1830, and Hegeman in 1870, all of whom confirm the accounts of its ruggedness and inaccessibility. The W. coast is better known. It is generally rocky and high, but sometimes flattens into low valleys, penetrated by numerous inlets and fiords, some of which extend far inland. Into most of these come down glaciers from the great glacier which appears to cover the whole interior. About lat. 70° is Disco island, lying in the mouth of Disco bay, and numerous smaller islands line the entire coast. Melville bay is a large and wide indentation, usually filled with floating ice. Its N. shore is formed by Hayes peninsula, into which makes Wolstenholme sound. Inglefield gulf is the next indentation, N. of which lies Prudhoe land. In the W. extremity of this is Lifeboat cove, the winter quarters of the *Polaris* in 1872-3. Further N. is the great Humboldt glacier, which extends over almost an entire degree of latitude, between lat. 79° and 80°. The whole coast here is a *mer de glace* formed by the crowding toward the sea of the glaciers, which, raised finally by the water beneath, break off with loud detonations, and floating free become icebergs. This is one of the principal sources of the icebergs of the N. Atlantic. Next is a peninsula called Washington land, with South fiord on its N. side, an inlet opening into Hall basin and extending far inland. Above Hall basin is Robeson strait, first explored in 1871 by Capt. Charles F. Hall, who named the several harbors along the coast *Polaris bay*, *Thank God bay*, *Newman bay*, and *Repulse harbor*. In *Thank God bay*, lat. 81° 38', the *Polaris* made her winter quarters in 1871-2. Dr. Pingel, a Danish naturalist, has established the fact that the W. coast from lat. 60° to 70° is gradually sinking at the rate of several feet in a century. At numerous places are submerged ruins, some not more than 75 years old, and the present Greenlanders avoid building near the water's edge. The interior is buried under a colossal mass of ice, which conceals all the minor ridges and valleys, and permits but a few steep mountains to protrude. This ice is continually moving seaward, a very small part of it eastward and the rest westward. The greatest discharge

is through the large friths, down which the ice moves in masses several miles wide, until, reaching deep water in Baffin bay, it breaks up and forms icebergs. Rink counted 22 great ice streams on the coast, indicating as many concealed valleys. Large streams of muddy water pour out from under the ice, even when it is 2,000 ft. thick, showing that a powerful grinding action is going on upon the surface of the rocks beneath.—The rocks of the coast are chiefly granite, gneiss, porphyry, slate, and calcareous formations. On the E. coast Scoresby found the slates of the coal formation, containing impressions of extinct species of tropical plants, like those of the same strata in more southern latitudes. Good coal is mined in abundance on the island of Disco, and at various places on the mainland are found silver, copper, iron, tin, lead, zinc, plumbago, arsenic, molybdenum, and other metals. The Swedish scientific expedition of 1871 found immense masses of meteoric iron on the coast, between the ebb and flow of the tide. One specimen weighing 49,000 lbs. Swedish, with a maximum sectional area of 42 sq. ft., is now in the royal academy at Stockholm, and another of 20,000 lbs. in the museum of Copenhagen. They contain 5 per cent. of nickel and from 1 to 2 per cent. of carbon. Asbestos, serpentine, zircon, gadolinite, tourmaline, iolite, rock crystal, and garnets also occur; but the only mineral exported is cryolite, from the mine at Iviktut, on the fiord of Arsut. About 100 miners are employed, and the annual product is from 10,000 to 12,000 tons, one half of which is sent to Denmark and the remainder to the United States, where it is made into commercial soda by the Pennsylvania salt company. A royalty of 20 per cent. is paid to the Danish government; and as the season of working is short and the navigation of the fiord is attended with danger on account of icebergs, the mine yields but little profit.—The climate is considered healthy by the Danes, and in S. Greenland is less rigorous than the high latitude and the immense fields of ice would indicate, the cold being greatly modified by the sea. On the E. coast the mean temperature is below the freezing point, but it is milder on the W. coast. Further N. the cold is intense, exceeding that of corresponding latitudes in Lapland. According to Dr. Hayes, the mercury stood at  $-68^{\circ}$  F. in March, 1861, in lat.  $70^{\circ} 30'$  N.; but in 1871 Capt. Hall found a much milder climate at his winter quarters in lat.  $81^{\circ} 38'$ ; the plain surrounding Thank God bay was free from snow in June, and the ground was covered with herbage, on which numerous herds of musk oxen found pasture, and rabbits and lemmings abounded. The wild flowers were brilliant, and large flocks of birds flew northward. This would indicate either an exceptional season, or that the climate is less rigorous toward the pole. Generally the winter cold is interrupted by thaws, which last sometimes for weeks. Through June and

July the sun is constantly above the horizon. The earth begins to thaw in June, and in July the ice is melted away in the southern fiords, and small streams, flowing from the interior, feed a few unimportant lakes, which remain open for a brief season. But even in the heat of summer ice can always be found a short distance below the surface of the ground. Permanent springs are almost unknown, but Dr. Kane found one at Godhavn, Disco, which had a winter temperature of  $33^{\circ}$  F., and Giesecke speaks of a thermal spring which maintained a temperature of  $104^{\circ}$ . The heat of the long summer day evaporates the water left by the tide in the hollows and clefts of the rocks and leaves a fine salt. Fogs prevail from April to August. Little rain falls, especially in the north. Gales are infrequent, but in the autumn they rage sometimes for days with great fury. There is occasional lightning, but no thunder. The aurora borealis is often seen in winter, frequently so bright as to cause the stars to disappear, and mirage is common on the coast.—The vegetation is slight, but it exceeds that of high mountainous districts in warmer latitudes. Dr. Hooker noted that most of the 320 phænogams and vascular cryptogams which make up the flora of Greenland were of Scandinavian origin, and that few American types were found, notwithstanding the comparative nearness of the continent. A few additional species have since been discovered. Mosses, lichens, and a few grasses and stunted plants and shrubs grow even in the far north, and furnish food for the reindeer, bear, and musk ox. Dr. Hayes noticed at Pröven, among other flowers, the golden-petalled poppy (*papaver nudicaule*), the dandelion (*contodon palustre*), the buttercup (*ranunculus nivalis*), the saxifrages, purple, white, and yellow, the *potentilla*, the purple *pedicularis*, and the *andromeda*. In sheltered places the pine, alder, and birch attain a height of barely 6 ft. and a stem of but 3 or 4 in. in thickness, and the willow becomes little more than a running vine. The scant soil is so full of fibrous roots that when cut and dried it is used for fuel. Attempts to raise oats and barley are unsuccessful, but potatoes are grown in the south. Turnips attain only the size of pigeons' eggs, and cabbages are very small. The radish is the only vegetable that is unchecked in its growth.—The seas around Greenland abound with animal life. The great rorqual whale, which attains sometimes a length of 120 ft., the more valuable mysticetus, or true whale, and other varieties, make them their resort. The walrus, the narwhal, the porpoise, and the seal are found on all the coasts. The arctic shark (*squalus borealis*) abounds, and is taken for the sake of the oil extracted from its liver, which is preferred to the best seal oils. Smaller fish are found in all the bays, and various kinds of crabs and shrimps exist in great numbers. Sea fowl in vast flocks frequent the coast, among them the little auk, guillemot, petrel, gull,

goose, and duck. There are traditions of the great auk, but it has not been seen by late explorers. The eider duck visits the most northern shores in the spring and raises its young. Other birds often seen are the raven, ptarmigan, grouse, tern, sandpiper, plover, dovekie, and snow bunting. In the more northerly parts the polar bear and the musk ox are found, but they are seldom seen in the south, excepting in severe winters, when it is difficult to paw the snow from the scant vegetation. In summer the bears live upon seals, which they catch on the ice. The reindeer, once abundant, are becoming scarce on the coast, the natives having hunted them with great persistency since the introduction of rifles; it is said that at least 10,000 have been killed in the past 30 years in the district of Omenak. Two species of fox, the white and the blue, abound. The skins of the blue fox are much sought after, the fur commanding a high price. The domestic animals are sheep, a few cattle, and dogs, the last of which constitute the chief wealth of the Greenlanders, who train them to draw sledges. They relapse sometimes into the savage state and roam in packs, hunting the reindeer.—With the exception of about 300 Europeans, mostly Danes, the population is composed entirely of Esquimaux, who live by hunting and fishing. A few live on the E. coast, below lat. 65°, but all the villages and settlements are on the W. coast, upon the low lands along the fiords. After years of discouraging effort on the part of the missionaries, all the natives have been converted to Christianity. They have given up their nomadic habits and enjoy the benefits of civilization, while they are afflicted with fewer of its vices than are the Indians who have come in contact with the white man elsewhere. Liquor is prohibited in all the settlements, and it is only once a year, on the king's birthday, that every man in Greenland is permitted to receive from the government storehouses a glass of schnapps, to drink the health of his sovereign. For administrative purposes the country is divided into two inspectorates, North and South Greenland. North Greenland is subdivided into seven districts, Upernavik, Omenak, Ritenbenk, Jacobshavn, Godhavn, Christianshaab, and Egedesminde, the last being the most southerly. Godhavn (Good Harbor), on the S. side of the island of Disco, in lat. 69°, has a population of 250, and is the residence of the inspector. The districts of South Greenland are, beginning with the most northerly, Holsteinborg, Sukkertoppen, Godthaab and Nye Herrnhut, Lichtenfels, Frederikshaab, and Julianeshaab. Godthaab, in lat. 64°, the residence of the inspector, has a population of 740. Each of these 13 districts has a director (*colonibestyrrere*), who is assisted in his administrative duties by a parliament chosen from the principal men. Julianeshaab, the chief district, comprises all the coast from Cape Farewell to lat. 61°. The town is in lat. 60°

44', on the fiord of Igalliko, a large inlet from the sea, from 2 to 5 m. in width, which is so shut in by the mountains that no glacier finds its way into it. Along its banks are still to be seen the ruins of the ancient Norse settlements. The town has a population, according to some authorities, of 2,600, but according to Dr. Hayes of only 800. The settlements of Nye Herrnhut, Lichtenfels, Frederiksdal, and Frederikshaab belong to the Moravian missions. The rest of the coast is in charge of the Lutheran missions, which are under the direct patronage of the government, and are administered by a board appointed by the Danish crown. The Moravians depend for their supplies upon private negotiations and the courtesy of Danish vessels.—The whole trade of Greenland is a monopoly of the crown of Denmark, and is carried on under the direction of the Greenland trading company (*Kongelige Grönlandske Handel*), an association founded in 1781, and controlled by a directory in Copenhagen. Each settlement is presided over by an agent, either a Dane or a half-breed, who keeps the company's accounts, disposes of stores, and gathers products. The stores are brought annually from Denmark to Julianeshaab, whence they are distributed to the various outposts. The chief exports from Greenland are stock fish (cod dried without salt), the skins of the seal, fox, and reindeer, whale and seal oil, blubber, eider down, and cryolite. The imports are grain, coffee, sugar, tobacco, brandy, and firewood. The expenses are so great that the trading company pays but a small sum annually into the royal treasury.—Greenland was discovered by the Northman Gunnbjörn, who saw its E. coast in 876 or 877; but he was wrecked on the rocks afterward called by his name, and did not land upon it. In 983 Eric the Red (so called from the color of his hair), son of a jarl of Jadar in Norway, set sail from Bredifjord, Iceland, in search of the land seen by Gunnbjörn, of which a tradition still lingered in Iceland. He doubled Cape Farewell and sailed up the W. coast to the present site of Julianeshaab, where he saw large herds of reindeer browsing on the meadow lands. The country pleased him, and he named it Greenland, and the inlet Ericsfjord. In 985 Eric returned to Iceland, and again set sail with 25 ships loaded with emigrants and the means of founding a colony. He reached Ericsfjord with 14 of these ships, the rest having been lost by the way or forced to put back, and built a settlement far up the fiord. The town grew and prospered, and in time the coast was explored and new plantations were founded. How far N. the Norsemen penetrated is not known, but an inscribed pillar, erected in 1135 on one of the Woman's islands on the E. shore of Baffin bay, and found there in 1824 by Sir Edward Parry, proves that one of their expeditions went as far as Upernavik, lat. 72° 50', and "cleared ground" there. As no trees grow in that region now, it is probable that the land was then

far more habitable than at present. The early chroniclers, too, make very little mention of ice, and there are evidences that the soil bore more generously in those days. Eric found no indigenous race, and he and his followers became the sole tenants of the land. The several settlements around Ericsfiord were called collectively Östre Bygd (East country), and the more northerly plantations Westre Bygd (West country). At one time there were more than 300 farms and villages between Disco and Cape Farewell. Churches and monasteries were built, and in the 12th century Greenland was erected into a bishopric, it having been previously a dependency of the see of Iceland. Seventeen successive bishops held the see of Gardar, the last of whom was consecrated in 1406. No Esquimaux (Skralinger) are mentioned by the chroniclers until the 14th century, when Thorwald saw them on the coast of Labrador. Toward the middle of this century a horde of Skralinger appeared on the borders of the Westre Bygd, and 18 Norsemen were killed in an encounter with them. When the news reached the Östre Bygd in 1349, Ivar Beer went with a force to the rescue; but he found only the ruins of the colony. Toward the close of the 14th century Greenland was visited by Nicolò Zeno, a Venetian navigator. In 1409 the bishop's see was abandoned. A letter from Pope Nicholas V. to the bishop of Iceland, written in 1448, mentions the descent of a hostile fleet on the coast about 80 years before, which laid waste the country with fire and sword, so that the organization of the colonies was destroyed; and we hear no more of Greenland until the time of the Elizabethan navigators. In 1576 Martin Frobisher, sailing in quest of a N. W. passage to China, came in sight of the E. coast in lat. 61°, and rounded Cape Farewell. Other navigators followed, and attempts were made to recover the lost colonies during the succeeding century; but it was not till 1721, when the Danish missionary Hans Egede established himself at Godthaab, that any success was attained. The Moravian missions were founded soon after, and the settlements have since continued to grow. Even the sites of the ancient colonies were unknown until a recent period. In 1829 the king of Denmark sent an expedition under Capt. Graah to determine the site of the Östre Bygd, which was supposed to be on the E. coast, the ruins at Igalliko fiord being taken for those of the Westre Bygd. He found reasons for believing that both settlements were on the W. coast, and within a few years it has been demonstrated beyond a doubt that Igalliko fiord, or Ericsfiord, was the site of Eric's long lost colony.

**GREENLEAF, Simon**, an American jurist, born in Newburyport, Mass., Dec. 5, 1783, died in Cambridge, Oct. 6, 1853. He practised law in Massachusetts and afterward in Maine, was reporter of the supreme court of Maine from 1820 to 1832, and during this period published nine volumes of reports, and a treatise on the

"Origin and Principles of Free-Masonry" (Portland, 1820). In 1833 he became professor of law in Harvard university, and held this office till 1848. In 1840 he published a volume of "Overruled, Denied, and Doubted Decisions and Dicta," which was expanded in subsequent editions to three volumes. In 1846 he published an "Examination of the Testimony of the Four Evangelists, by the Rules of Evidence as administered in Courts of Justice, with an Account of the Trial of Jesus." In 1849 he published an edition of Cruise's "Digest of the Law of Real Property." But his great work was a "Treatise on the Law of Evidence" (3 vols., 1842-'53).

**GREEN MOUNTAINS**, the northernmost portion of the Appalachian chain, extending from Canada S. through Vermont. To this state, over which they are largely spread, they give its name, from the term *monts verts* by which they were known to the early French settlers. The continuation of the range through Massachusetts and Connecticut is also known to geographers as the Green mountains, but by the inhabitants of these states other names are applied to them; as the Hoosac mountains in Massachusetts for that portion lying between the Connecticut and Housatonic rivers, and constituting the most elevated portion of the state, and the Taconic mountains for the western part of the range, along the New York line. These ranges extend into Vermont near the S. W. corner of the state, and join in a continuous line of hills, that pass through the western portion of the state nearly to Montpelier. Without attaining very great elevation, these hills form an unbroken watershed between the affluents of the Connecticut on the east and the Hudson and Lake Champlain on the west, and about equidistant between them. South from Montpelier two ranges extend, one N. E. nearly parallel with the Connecticut river, dividing the waters flowing E. from those flowing W.; and the other, which is the higher and more broken, extending nearly N. and near Lake Champlain. Through this range the Onion, Lamoille, and Missisque rivers make their way toward the lake. Among the principal peaks are Mt. Mansfield, 20 m. N. W. of Montpelier, 4,279 ft. above the sea; Camel's Hump, 17 m. W. of Montpelier, 4,188 ft.; Killington peak, near Rutland, 3,924 ft.; and Ascutney, in Windsor co., near the Connecticut river, 3,320 ft.—This portion of the Appalachian chain neither possesses the marked uniformity of elevation and parallelism of its ridges that characterize the same chain further S., nor has it the abruptness and precipitous outlines of the granitic summits of the White mountains. The body and eastern side of the Green mountain range is generally of primitive geological structure, consisting of hornblende, granite, gneiss, &c. The rocks of the western slope are principally old red sandstone, containing iron ore and manganese. The general range of the rocks is about N. 15° E., with a prevailing dip

of 30° to 55°, and sometimes more, toward the east. These give a comparatively smooth outline to the surface of the hills; and though the soil they produce is not generally fertile, the slopes are covered on the disappearance of the snow with fine pastures of rich green grass, which may have given the mountains their name, though this is commonly referred to the growth of evergreen forest trees, which abound upon the poorer lands and along the margins of the streams. Upon the better lands is found the hard-wood growth of beech, birch, sugar maple, white oak, ash, &c. The mineral products of the Green mountains are very valuable, including excellent iron ores, manganese, marble, slate, &c. (See VERMONT.)

**GREENOCK**, a parliamentary borough and seaport town of Renfrewshire, Scotland, on the S. shore of the estuary of the Clyde, 18 m. W.

N. W. of Glasgow; pop. in 1871, 57,138. It stands partly on a narrow plain, and partly on the declivity of a high hill. It has about 35 churches and chapels, a Latin school, a town library of 12,000 volumes, a mechanics' hall, excellent docks and wharves, and in the neighborhood an aqueduct 3 m. long. There are numerous sugar refineries and iron foundries, considerable ship building, in particular of iron ships, and manufactories of sail cloth, shoes, soap, and candles. The entrances at the port in 1871 were 64 steamers and 562 sailing vessels; the clearances, 22 steamers and 339 sailing vessels. The imports were valued at £6,117,796 (from the United States, £53,453); the exports at £649,313 (to the United States, £63,521). All the steamers of the Clyde touch at this port. The Victoria dock, opened Oct. 17, 1850, is a tidal basin covering an area of six

Greenock.

acres, and exceeding 30 ft. in depth; it cost upward of £120,000.—Until 1697 Greenock was a small fishing village. James Watt, the inventor of the steam engine, was a native of the town, and in 1838 a marble statue by Chantrey was erected to him here.

**GREENOUGH, Horatio**, an American sculptor, born in Boston, Sept. 6, 1805, died at Somerville, near Boston, Dec. 18, 1852. A French sculptor named Binon, resident in Boston, was his first master; and he enjoyed the friendship and advice of Washington Allston. Before completing his college course he went to Rome, where he arrived in the autumn of 1825. He returned to Boston in 1826, and after modeling busts of John Quincy Adams, Chief Justice Marshall, and others, returned to Italy and settled in Florence. His first commission was from James Fenimore Cooper, for whom he executed his "Chanting Cherubs." In 1831 he went to Paris to model the bust of Lafayette, and after his return to Florence received liberal commissions from his countrymen, principally for busts. To Cooper he was indebted for the commission from congress to execute his colossal statue of Washington, which was

finished in 1843, after many years' labor. During this time he executed, among other original works, the "Medora" for Mr. Gilmore of Baltimore, the "Angel Abdiel," and the "Venus Victrix" in the gallery of the Boston Athenæum. A second commission from congress employed him for some years subsequent to this, and in 1851 he returned to the United States to superintend the placing in Washington of his group of the "Rescue." Many vexatious delays prevented the arrival of the work from Italy, and Greenough was attacked by brain fever soon after he had commenced a course of lectures on art in Boston, and died after a short but severe illness. At his death he had sketches of work for 20 years. A "Memorial of Horatio Greenough," published in 1853, contains a collection of his papers on art and other subjects, preceded by a life of the artist by H. T. Tuckerman.

**GREENPORT**, a village and port of delivery in the town of Southold, Suffolk co., N. Y., on the S. side of the N. E. point of Long Island, 95 m. E. N. E. of New York; pop. in 1870, 1,819. It has an excellent harbor at the entrance to Peconic bay, capacious enough for

the largest ships, and seldom obstructed by ice. Coasting vessels are owned here, and there are several ship yards. The village contains seven churches, two newspaper offices, a stereotype foundry, a national bank, a public school, and four large hotels. It is the E. terminus of the Long Island railroad. Great quantities of oil are manufactured in floating and stationary factories, from menhaden or bunkers. Torpedo fireworks are extensively made, chiefly by Germans and their children. For a few years past Greenport has been rapidly rising in importance as a summer resort and watering place, on account of its superior facilities for boating, fishing, and bathing. A large hotel was erected on the S. side of the bay in 1872, and a still larger one has lately been completed near by. In summer there are steamboat lines to New York, New Haven, and Newport.

**GREEN RIVER.** I. A considerable stream which rises in Lincoln co., Ky., flows W. past the Mammoth cave, and, after receiving Big Barren river, bends N. W. and enters the Ohio 9 m. above Evansville in Indiana; length, nearly 300 m. It is 200 yards wide at its mouth, and in the lower part of its course is navigable by steamboats at all seasons, while, by means of dams and locks, small steam vessels can ascend to Greensburg, a distance of 200 m. The upper part of its valley is occupied by cavernous limestone, and the lower abounds in coal. II. One of the constituents (properly the upper continuation) of the Colorado of the West. It rises in the Rocky mountains near Fremont's peak, in the W. part of Wyoming territory, in about lat.  $43^{\circ} 15' N.$ , lon.  $109^{\circ} 45' W.$ , flows S., turns S. E. through the N. E. corner of Utah, entering the N. W. corner of Colorado, then bends S. W. and reenters Utah, and afterward pursues a general S. course to its junction with the Grand. Its entire course is about 500 m. Besides numerous affluents which it receives in Wyoming, the principal tributaries are the Yampah or Bear and the White from the east, and the Uintah, White, Little White, and San Rafael from the west. Green river for the greater part of its course flows through deep and precipitous cañons. It first enters the Uintah mountains in the extreme N. W. corner of Colorado, at a point called Flaming Gorge, just below which the walls of the cañon are nearly 1,500 ft. high. The stream is swift, the descent being in places 20 ft. to the mile. Rapids and cataracts, some of them of great height, are frequent. There is generally on the one side or the other a narrow strip of land forming the valley of the river, but for considerable distances the walls rise perpendicularly from the water's edge to the height of 5,000 or 6,000 ft., and at one point of 6,500 ft.

**GREENSAND,** an important member of the cretaceous group of stratified rocks. In Europe it is found in both divisions of these rocks, the upper and lower, the clay called gault being intermediate. The chalk overlies the greensand; and the Wealden clays, where they appear at

all, separate it from the next inferior group, the oolite. In the United States, the greensand is not found throughout the range of the cretaceous group around the southern termination of the Alleghanies and thence west. It is indeed little known except on its range through New Jersey. The tract it occupies, commencing at the N. E. on Sandy Hook bay, extends S. on the coast to Shark inlet, giving a width across the Atlantic outcrop of the formation from N. W. to S. E. of about 18 m. Its length is directed S. W. across the state, the tract gradually growing narrower and terminating in a point at Salem, opposite the N. part of Delaware. Its N. line approaches within  $1\frac{1}{2}$  m. of the Delaware at Bordentown, and is but little further back from it a few miles below Camden, opposite Philadelphia. The dip of the formation is toward the S. E. at a small angle. On this side its uppermost strata disappear beneath the sands which cover the country; and on the N. W. come up from beneath its lowest beds the clays, well known at Amboy and other points on their range toward the S. W. for their use in pottery and the manufacture of fire brick. A straw-colored limestone, which occasionally appears overlying the greensand on its S. E. margin, calls to mind by its position and the numerous marine fossils it contains the calcareous strata of Europe known as the chalk. The whole thickness of the strata known as greensand is about 100 ft., but one principal bed is recognized among the other strata of sand and clays and intermixed greensand, which is about 30 ft. thick. This is in great part, sometimes wholly, made up of small round dark granules; several are often united in one, and a quantity of them moistened may sometimes be kneaded like clay. The grains are commonly of deep green color, sometimes bluish, and sometimes a dark chocolate; but whatever their external color may be, they are all bright green when well washed, and especially when crushed. Clay and white silicious sand are commonly intermixed in variable proportions with the greensand. In some places fossil shells and other marine organic remains abound in the greensand, being grouped together in layers a few feet in thickness. The species are numerous and often beautifully preserved. This is especially the case with those found in the overlying yellowish limestone; all are extinct. Of 60 shells collected by Lyell, 5 proved to be identical with European species, viz.: *ostrea larva*, *O. vesicularis*, *gryphaea costata*, *pecten quinquecostatus*, *belemnites mucronatus*. Prof. Forbes regarded 15 of the 60 "as good geographical representatives of well known cretaceous fossils of Europe." Besides these organic remains are found teeth and vertebrae of sharks and some other fishes, also teeth and other vestiges of crocodiles and several other saurians, some of gigantic size, one of the largest of which, the *hadrosaurus Faulkii*, has been restored from a few bones by Prof. B. Waterhouse Hawkins, and is now deposited in the museum of the Philadelphia academy

of science. Remains of several crustaceous animals, as crabs, are also met with, and finely preserved specimens of various species of the echinodermata, and of zoöphytes, sponges, &c. The shells which most abound in the greensand, occasionally making up the principal portion of the layers in which they occur, are gryphæas, terebratulas, ostreas, belemnites, and the *exogyra costata*, the last named a very common and large bivalve peculiar to the cretaceous group.—The greensand is of importance for its fertilizing property; and this is found to be derived, not from the calcareous nature of its organic remains, but from the green grains which commonly make up the greater portion of its beds. These, as they are found in New Jersey, when separated from adhering sand and clay, present a composition varying only within a limited range, and not differing from that of the greensand near Havre, France, as determined by Berthier. But according to the analysis of Dr. Turner, the same mineral substance of Kent, England, is deficient in the very element, potash, to which its valuable qualities in this country are essentially owing. Some of the same material also met with in Marshfield, Duxbury, and Gay Head, Mass., resembles the English in this particular. The mean of four analyses of New Jersey greensand, made by John C. Smock and E. H. Bogardus in 1865-'8, and the result of the examination of foreign specimens, are given in the following table:

CONSTITUENTS.	N. J.	France.	Gay Head.	England.
Silica.....	46·50	50·00	56·70	48·50
Potash.....	9·00	10·90	.....	.....
Lime.....	1·50	.....	1·62	.....
Alumina.....	8·00	7·00	18·32	17·00
Protoxide of iron.....	5·00	.....	.....	.....
Peroxide of iron.....	21·00	21·00	20·10	22·00
Water.....	9·00	11·00	7·00	7·00
Magnesia.....	.....	.....	1·18	8·80

In New Jersey the greensand (there called marl) is dug from pits during the winter, and brought out upon the fields, where it is spread to be ploughed in. The effect is experienced with the first crop, and continues for several years.—The investigations of Ehrenberg first showed that many of the greensand grains are casts of the microscopic shells of *polythalamia* (the many-chambered) and of other organic bodies. The shells themselves had disappeared; but the internal form of their cavities was retained in the more durable silicate of iron, which took the place of the animal bodies as these decayed, and preserved their shapes. Even the very finest canals of the cell walls, and all their connecting tubes, are thus petrified and separately exhibited. Many of the grains which cannot be recognized as of this origin still suggest some connection with animal bodies by their forms being sometimes lobed and again presenting the appearance of coprolites. Prof. Bailey by his experiments confirmed the conclusions of Ehrenberg, and, extending his investigations to cretaceous rocks

from Alabama and W. Texas, found attached to them grains of greensand exhibiting the same phenomena. From specimens of marl and limestone of the eocene of the southern states he also succeeded in bringing to light similar grains of the same character by dissolving away with dilute acid the calcareous matters. One of his specimens was brought up in sinking the artesian well at Charleston from the depth of 140 ft. The soundings of the coast survey brought up from the depths of the ocean, in the Gulf stream and the gulf of Mexico, something resembling greensand. Count Pourtales reports one sounding as of this character obtained in lat. 31° 32', lon. 79° 35', at the depth of 150 fathoms. This, as well as the others referred to, were examined by Prof. Bailey, who found them to be greensand, and that this is often in the form of well defined casts of *polythalamia*, minute mollusks, and branching tubuli. The material he found to be the same as that of the fossil casts; but the chief part of the soundings he found consisted of perfectly preserved shells of the same species, which retained their brilliant colors, and gave evidence by treatment with acid that the soft parts were still present, thus proving the recent existence of the animals. Hence it appears that in some deep seas the production of greensand is still going on, and formations of this obscure material are there growing up by the same agencies which elaborated those of ancient geological periods.

**GREENSBORO**, a town and the capital of Hale co., Alabama, 80 m. W. by N. of Montgomery; pop. in 1870, 1,760, of whom 972 were colored. It is surrounded by large cotton plantations, has a flourishing trade, and contains a court house, a jail, two banks, and several churches, and has a weekly newspaper. It is the seat of the Southern university (Methodist), which in 1872 had 13 professors and instructors, 120 students, and a library of 10,000 volumes.

**GREEN SNAKE.** See COLUBER.

**GREENSTONE**, a trappean rock of granular texture, either crystalline or compact, composed of hornblende and orthoclase, or augite with either orthoclase or albite. When albite replaces orthoclase, the rock is called diorite. Its greenish color is due to minute quantities of chromium compounds. It is called trap when in columnar form. Basalt is essentially the same rock. Being of irregular fracture, too hard to cut, and lacking uniform grain, it is unfit for use in building except of rough walls. (See BASALT, and TRAP.)

**GREENUP**, a N. E. county of Kentucky, bordering on the Ohio river; area 480 sq. m.; pop. in 1870, 11,463, of whom 461 were colored. It is hilly and well timbered, has a fertile soil, and abounds in coal and iron. The chief productions in 1870 were 29,842 bushels of wheat, 164,650 of Indian corn, 26,864 of oats, 9,498 of potatoes, and 1,668 tons of hay. There were 747 horses, 533 milch cows, 1,624 other cattle, 2,086 sheep, and 2,834 swine; 7

blast furnaces, 3 tanneries, 1 currying establishment, 2 lime kilns, 3 saw mills, and 1 railroad repair shop. Capital, Greensburg.

**GREENVILLE. I.** A S. E. county of Virginia, bordering on North Carolina, bounded N. by the Nottoway river, and watered by the Meherrin river; area, 300 sq. m.; pop. in 1870, 6,362, of whom 4,207 were colored. It is traversed by the Richmond, Fredericksburg, and Potomac railroad, and the Gaston branch. The surface is level and the soil moderately fertile. The chief productions in 1870 were 5,524 bushels of wheat, 112,392 of Indian corn, 13,509 of oats, and 33,200 lbs. of tobacco. Capital, Hicksford. **II.** A N. W. county of South Carolina, bordering on North Carolina, and bounded W. by Saluda river; area, about 800 sq. m.; pop. in 1870, 22,262, of whom 7,141 were colored. The Blue Ridge touches the N. border, and the rest of the surface is pleasantly diversified. The soil is generally fertile. The Greenville and Columbia railroad terminates at the county seat, and the Atlanta and Richmond Air-Line railroad crosses the county. The chief productions in 1870 were 44,421 bushels of wheat, 355,526 of Indian corn, 23,698 of oats, 22,499 of sweet potatoes, and 1,864 bales of cotton. There were 1,556 horses, 1,184 mules and asses, 3,561 milch cows, 5,111 other cattle, 7,640 sheep, and 17,400 swine; 4 cotton mills, 2 tanneries, 2 currying establishments, and 1 paper mill. Capital, Greenville.

**GREENVILLE. I.** A city and the capital of Greenville co., South Carolina, on Reedy river, an affluent of the Saluda, near its source, and on the Atlanta and Richmond Air-Line railroad, at the terminus of the Greenville and Columbia line, 95 m. N. W. of Columbia; pop. in 1870, 2,757, of whom 1,375 were colored. Having an elevated and healthy situation at the foot of Saluda mountain, it is a favorite summer resort. It is the seat of several Baptist educational institutions. Furman university, organized in 1851, in 1873-'4 had 4 professors, more than 50 students, and a library of 2,000 volumes. The Greenville high school, formerly in name and still practically the preparatory department of the university, had 4 instructors and more than 100 pupils. Greenville Baptist female college, organized in 1854, had 9 professors and instructors and about 100 students. The Southern Baptist theological seminary was organized in 1858, and in 1873-'4 had 5 professors, 60 or 70 students, and a library of 3,000 volumes. Greenville has six churches, a national bank, grain mills, a saw mill, planing mills, a coach and wagon factory, a boot and shoe factory, a cotton factory, and two weekly newspapers. **II.** A town and the capital of Greene co., Tennessee, on the East Tennessee, Virginia, and Georgia railroad, 220 m. E. of Nashville, and 66 m. E. by N. of Knoxville; pop. in 1870, 1,039, of whom 253 were colored. It is the seat of Greenville and Tusculum college, organized in 1868 by the union of Greenville and Tusculum colleges,

founded respectively in 1794 and 1844. In 1872 it had 10 professors and instructors, 12 collegiate and 87 (21 female) preparatory students, and a library of 5,000 volumes. Greenville has three weekly newspapers.

**GREEN VITRIOL.** See COPPERAS.

**GREENWICH**, a town and borough of Fairfield co., Connecticut, on Long Island sound, and on the New York and New Haven railroad, 30 m. N. E. of New York and 42 m. S. W. of New Haven; pop. in 1870, 7,644. The town borders on the state of New York, forming the S. W. extremity of New England, and contains a savings bank, two hotels, 19 public schools, an academy, and 15 churches. The village is beautifully situated near the water, and contains the residences of many people doing business in New York. Putnam's hill, famous as the precipice down which Gen. Putnam galloped in his perilous escape from the British in 1779, is in the S. W. part of the town.

**GREENWICH**, a town and parliamentary borough of Kent, England, on the right bank of the Thames, 5 m. S. E. of St. Paul's cathedral, London; pop. of the town in 1871, 169,361. It stands mostly on low, marshy ground. There are numerous churches, chapels, schools, and charitable institutions. But the great objects of attraction are its hospital for seamen, and its observatory, whence longitude is reckoned by the British and often by other geographers. (See LONGITUDE.) The hospital, first opened in 1705, occupies the site of an ancient royal palace called Greenwich house, Placentia, or "The Pleasaunce," a favorite residence of several sovereigns, and the birthplace of Henry VIII., Queen Mary, and Queen Elizabeth. It consists of quadrangular buildings, enclosing a square, each bearing the name of the sovereign in whose reign it was erected. The N. W. quadrangle contains the apartments of the governor and the libraries of the officers and pensioners. The N. E. quadrangle is inhabited by the officers and men. In the S. W. building is the painted hall, adorned with the portraits of British naval heroes and representations of naval victories. In the S. E. division is the chapel, the interior of which is richly decorated. Previous to 1865 the institution generally supported about 2,700 in-pensioners, and from 5,000 to 6,000 out-pensioners. The in-pensioners were amply supplied with food, uniformly clothed, comfortably lodged, and allowed one shilling a week each for tobacco. The out-pensioners receive each an annual stipend which averages about £12. There is an infirmary connected with the hospital, and a school for the children of decayed non-commissioned officers, seamen, and marines, which is attended by 800 scholars. The governorship of the hospital is usually held by some veteran naval commander. By an act of parliament passed in 1865 the in-pensioners were permitted to reside where they pleased, and were allowed two shillings a day besides their service pension. All but 200 or 300

infirm and bed-ridden pensioners thereupon left the hospital, and it is now kept as a medical hospital for wounded seamen in time of war. The income of the hospital amounts to

about £150,000 a year. The observatory was erected by Charles II. for the advancement of navigation and nautical astronomy. Its organization is very complete. It is charged with

Greenwich Hospital.

the transmission of time throughout England by means of electro-magnetic circuits, in addition to its ordinary functions. Greenwich has several large factories, extensive engineering establishments, iron-steamboat yards, ropewalks, &c. The borough comprises Greenwich, Deptford, and Woolwich.

**GREENWOOD. I.** A S. E. county of Kansas, intersected by Verdigris and Fall rivers; area, 1,155 sq. m.; pop. in 1870, 3,484. The surface is undulating and the soil fertile. The chief productions in 1870 were 35,449 bushels of wheat, 173,590 of Indian corn, 24,492 of oats, 14,774 of potatoes, and 10,485 tons of hay. There were 1,638 horses, 2,323 milch cows, 5,427 other cattle, 3,575 sheep, 1,890 swine, and 5 saw mills. Capital, Eureka. **II.** An E. county of Colorado, bordering on Kansas; area, about 4,000 sq. m.; pop. in 1870, 510. It has since been absorbed by Bent and Elbert counties. It was intersected by Big Sandy creek, a branch of the Arkansas, and watered in the E. part by the head streams of Smoky Hill river. Irrigation is necessary. Buffalo grass and cactus abound. The Kansas Pacific railroad traverses the region. Capital, Kit Carson.

**GREENWOOD, Francis William Pitt**, an American clergyman, born in Boston, Feb. 5, 1797, died there, Aug. 2, 1843. He graduated at Harvard college in 1814, and immediately commenced the study of theology under the direction of Dr. Ware, approving in the main, then and for the rest of his life, the doctrines prevalent in Boston under the name of liberal Christianity. In October, 1818, he became pastor

of the new South church and society in Boston; but after a single year his course was arrested by a pulmonary disease. He went to England in 1820, but, not fully recovering his health, resigned his pastorate. He returned in the autumn of 1821, passed a little more than two years at Baltimore, preached occasionally, and wrote for and edited for nearly two years a periodical called the "Unitarian Miscellany." In 1824 he became colleague of Dr. James Freeman, pastor of King's chapel, Boston, who with the consent and coöperation of his society had revised the "Book of Common Prayer" there used so as to exclude the recognition of the Trinity. Bodily infirmities compelled Dr. Freeman to give up the pulpit in 1827, and Mr. Greenwood took the full charge. He had a strong taste for the natural sciences, conchology and botany being his especial favorites, and he was one of the first members of the Boston society of natural history. A return of hæmorrhage of the lungs compelled him to make a voyage to Cuba in 1837. While confined to a sick chamber the year before his death, he prepared for publication "Sermons of Consolation" (1842). He was also the author of "History of King's Chapel" (Boston, 1833), "Lives of the Twelve Apostles" (1838), "Sermons to Children," and numerous contributions to periodicals. After his decease Samuel A. Eliot edited two volumes of his sermons from the MSS., and prefaced them with a memoir of the author; and a volume of his miscellaneous writings was published by his son (1846).

**GREER**, the N. W. county of Texas, as claimed by the state authorities, lying between the forks of Red river; area, 3,480 sq. m.; still unsettled. There is considerable good land, but little timber. This region is claimed by the United States as being within the limits of the Indian territory.

**GREG, William Rathbone**, an English author, born in 1812. He has published "Investments for Working Classes" (1852); "Essays on Political and Social Science" (1854); "Creed of Christendom, its Foundations," &c. (1863); "Literary and Social Judgments" (1868); "Truth vs. Edification" (1869); "Why are Women Redundant?" (1869); "Political Problems for our Age and Country" (1870); "The Great Duel, its True Meaning and Uses" (1871); and "Enigmas of Life" (1872). He has been a frequent contributor to the English periodicals. Several of his works have been reprinted in the United States.

**GREGARINA**, the best known genus of the *gregarinidæ*, a division of protozoa, with no mouth and without the power of sending out the delicate filaments of sarcodæ characteristic of the foraminifera. They are among the lowest of the protozoa, parasitic, varying in size from a pin's head to half an inch in length; they infest the intestines of various animals, principally articulates, as the earth worm, lobster, beetle, and cockroach. They appear like a single cell, filled with a granular and fatty matter, with a nucleus and nucleolus; the external covering may be smooth, bristly, or ciliated. They have no definite organs, and the processes of nutrition and waste must be effected by the general surface of the body, as is common with internal parasites. In reproduction, the nucleus disappears, and the granular sarcodæ breaks up into little masses, which afterward become pointed, forming the so-called navicellæ; these escape from the ruptured cyst, giving rise to active sarcodæ masses, which have the property of throwing out processes, like the amœba; these in a suitable locality become developed into gregarinæ. One of the largest, said to be, with the exception of the yolk of the eggs of birds and some other animals, the largest known cell, the *G. gigantea*, is found in the intestine of the lobster; it is nearly two thirds of an inch long, and almost as wide.

**GRÉGOIRE, Henri**, a French revolutionist, born at Vého, near Lunéville, Dec. 4, 1750, died in Paris, May 28, 1831. He commenced active life as a parish priest, and being nominated by the clergy of Lorraine in 1789 to represent them in the states general, he at once took ground as a republican, and was one of the first of the clergy to take the oath of fidelity to the constitution. He voted against primogeniture and special privileges, and zealously advocated the admission of Jews and men of color to full rights of citizenship. Under the new constitution of the clergy the department of Loir-et-Cher in 1792 elected him bishop, on which he

assumed, from the seat of the episcopate, the appellation of bishop of Blois. In the convention he led the movement for the abolition of the regal office, and made a bitter speech against kings in general, ending by demanding that Louis Capet should be brought to trial. One maxim of his became a watchword of the revolution: *L'histoire des rois est le martyrologe des nations*. His oration caused him to be made, the same day, president of the convention. He was absent with three other delegates on a mission to revolutionize Savoy when the king was brought to trial, but with his colleagues he wrote from Chambéry to the convention, urging the condemnation of the king, though he afterward denied that he wished him to be condemned to death. Further, he says he endeavored to save the life of the king by proposing to abolish the death penalty. When Gobel, archbishop of Paris, assented to the worship of Reason, Grégoire boldly refused to follow his example. He contributed zealously to preserve the monuments of art, and extended his protection to men of letters and artists. In 1800 he entered the legislative body, and having been transferred in 1801 to the senate, formed one of the minority of five opposed to the accession of the first consul to the throne. He alone opposed the reestablishment of titles of nobility. Napoleon unwillingly, on the request of both houses of the legislature, afterward made him a count of the empire and officer of the legion of honor. He was also opposed to the emperor's divorce, and declined to be present at the marriage with Maria Louisa. On Napoleon's reverses in 1814 Grégoire pronounced a vehement oration against him. On the second restoration he was excluded from the institute, deprived of his bishopric, and compelled by the stoppage of his pension to sell his library for the means of support. He retired to Auteuil, where he passed the last 15 years of his life in literary labor. He never renounced his republican principles. The last offices of religion were denied him on his deathbed by his ecclesiastical superiors; but the civil power having interfered, funeral rites were performed over his body in the church of the Abbaye aux Bois by a proscribed priest. The people then took his remains in charge, and removing the horses from the hearse, drew it to the cemetery of Mont Parnasse. Bernardin de l'Oise describes Grégoire's character in saying that he wished to "Christianize the revolution." The most important of his numerous publications are his *Histoire des sectes religieuses* (2 vols., 1810); *Essai historique sur les libertés de l'Eglise gallicane* (1818); *De l'influence du Christianisme sur la condition des femmes* (1821); *Histoire des confesseurs des empereurs, des rois et d'autres princes* (1824); and *Histoire du mariage des prêtres en France* (1826). He also wrote a work entitled *De la littérature des nègres*, containing sketches of the lives and writings of negroes "who have distinguished themselves in science,

literature, and the arts." This work has been translated into English, and published both in Great Britain and the United States. His *Mémoires* were published in 1837.

**GREGORIAN CHANT**, a method of singing the psalms and litanies of the church, introduced by Pope Gregory the Great about 590. It was mainly founded on the Ambrosian chant, previously in use in the western churches, to the four authentic or principal modes of which Gregory, either for variety or convenience of the voice, added the plagal or collateral modes. His additional object in effecting this reform was to banish from the church all rhythmic singing, as too lively for the place and occasion, and to substitute in his own chant, which was called the *canto fermo*, a gravity and simplicity suited to the solemn offices of the church. He also established in Rome a school of instruction in the new method of singing, which existed for three centuries after his death. Notwithstanding the monotony of the Gregorian chant, its extreme simplicity and dissimilarity to secular music, or even to that at present employed in the services of the church, it is still in use, and during Lent and on other special occasions may be heard in all its ancient glory in Roman Catholic churches, and to a limited extent in those of other denominations. It has been supposed that fragments of the melodies sung in the celebration of the Eleusinian mysteries are discernible in the Gregorian chant.

**GREGOROVIVS, Ferdinand**, a German author, born at Neidenburg, Prussia, Jan. 19, 1821. He entered the university of Königsberg in 1838, studied theology and philosophy, and afterward devoted himself to poetry and history. His first important work was *Goethe's Wilhelm Meister in seinen socialistischen Elementen* (Königsberg, 1849), in which he showed a profound knowledge of the work of the great poet, and presented many striking views of modern life. He published in 1848 a small work on Poland, in 1849 *Polen- und Magyarenlieder*, and in 1851 the tragedy *Der Tod des Tiberius und Geschichte des römischen Kaisers Hadrian und seiner Zeit*. In 1852 he travelled through Italy, and the results of his studies and observations were published in *Corsica* (2 vols., Stuttgart, 1854), *Figuren, Geschichte, Leben und Scenerie aus Italien* (4th ed., Leipsic, 1874), *Lateinische Sommer* (1863), and *Siciliana* (3d ed., 1874). The last three have been published under the title *Wanderjahre in Italien*, including *Von Ravenna bis Mentana* (4 vols., 1874). He also published *Lieder des Giovanni Meli von Palermo* (1856), *Die Grabmäler der römischen Päpste* (1857), and a long poem, *Euphorion* (1858; illustrated ed., 1872). His most important works are *Geschichte der Stadt Rom im Mittelalter* (8 vols., Stuttgart, 1859-'72; 3d ed., 1874; Italian translation, Venice, 1874 et seq.), and *Geschichte der Lucrezia Borgia* (2 vols., 1874).

**GREGORY**, a S. county of Dakota, bounded N. E. by the Missouri river, recently formed, and not included in the census of 1870; area,

about 1,400 sq. m. It is separated from Nebraska on the south by the Niobrara and Keya Paha rivers.

**GREGORY**, the name of 16 popes. **I. Saint**, surnamed the Great, born of a noble family in Rome about 540, died March 12, 604. His parents were patricians of great wealth. His father, Gordianus, renounced his senatorial rank to become a clergyman, and when he died was one of the seven *regionarii* or cardinal deacons; and his mother, Sylvia, devoted herself at the same time to an ascetic life. To a commanding presence and affable manners Gregory united great learning and executive ability. He was appointed governor or prefect of Rome about 573, but soon abdicated the office, withdrew from the world, and, after his father's death, employed his revenue in founding religious institutions, changed his own house on the Cælian hill into a monastery, and himself became a monk in it. On seeing one day some handsome English youths exposed for sale in the market place, he exclaimed, "They would be angels rather than Angles, were they only Christians!" Carried away by the desire of converting England, he besought the pope to allow him to go thither; and he set out by night from Rome, but was followed and brought back by the people. Pope Pelagius II. named him one of the seven regional deacons, and shortly afterward sent him as legate to Constantinople. He convinced the heretic Eutychius of his error, won the good graces of the emperor Mauricius, and was recalled to Rome about 585. During this period he wrote his *Libri Moraliū*, a commentary on Job. In 590 the plague broke out in Rome, and Pope Pelagius having died of it, Gregory was unanimously chosen to fill his place. He wrote to the emperor Mauricius beseeching him not to ratify the election; but the letter was intercepted by the prefect of Rome, one of quite a different import despatched in its stead, and the consent of the emperor obtained without delay. Meanwhile Gregory had fled from Rome and concealed himself; but his retreat was discovered, and on Sept. 3, 590, he was consecrated in the church of St. Peter. Pestilence and famine were desolating Italy at that time, and hostile armies were on their march toward Rome. He called his clergy around him, labored at their head night and day to stay the ravages of the plague, collected funds and purchased large stores of grain in Sicily, which brought back plenty to the city, and by his eloquence arrested the invasion of the advancing Lombards. He bent his whole mind on reforming the abuses which had crept into the clerical body, many of which had become inveterate, and sent missionaries to all parts of the known world. Among them Augustin and his companions went by his order to England, which was soon converted to the faith. He extinguished Arianism in Lombardy, and combated it incessantly in Spain, where he won over to orthodoxy the king Recared; in Africa

he put down the Donatists, and in Constantinople opposed energetically the pretensions of the patriarch John the Abstinence to the title of œcumenical patriarch, assuming as his own title that of "servant of the servants of God," which was adopted by the subsequent bishops of Rome. Equally tolerant and zealous, while using every endeavor to spread the faith, he would have no other means employed for that purpose than those of an exemplary life and rational instruction. He reprimanded the bishop of Terracina, who would not permit the Jews to assemble for religious worship; and wrote in the same spirit to the bishops of Sardinia, Sicily, and Marseilles. At Cagliari a converted Jew had changed a synagogue which he owned into a Christian church; Gregory commanded that it be restored to its former use. He deplored the evils of slavery as it existed before his time, and seeing it aggravated by the barbarian wars, he emancipated all his own slaves as an example. His works, besides his *Libri Moralium*, are *Liber Regule Pastoralis*, 4 books of dialogues, and 14 books of letters. The best edition is that of the Benedictines (4 vols. fol., Paris, 1705). An old English version of his dialogues, edited by Henry James Coleridge, S. J., was published at London in 1874. A life of St. Gregory was written by Paul the Deacon, another by John the Deacon, and a history of his pontificate by Maimbourg. **II. Saint**, born in Rome in the latter half of the 7th century, died in February, 731. He was equally renowned for learning and virtue when elected to the papal chair, in May, 715. He found Constantinople given up to revolutions in the imperial palace, the coasts of Italy open to the incursions of the newly created Mohammedan navy, and the interior ravaged by the Lombards. The emperor Leo the Isaurian urged in both east and west the persecution of those who honored images, and Gregory opposed him, while upholding his authority in Italy. He built up at his own expense the ruined walls of Rome, purchased back from the Lombards the city of Cumæ, persuaded King Liutprand to restore Sutri to the emperor, and some time afterward stopped the united forces of Liutprand and the exarch of Ravenna at the gates of Rome, and induced them to spare that city. He was most zealous in promoting the conversion of infidels, sent St. Boniface to preach the gospel among the Germans, and wrote to Charles Martel to beg his protection for the missionaries. He restored the ruined monastery of Monte Cassino, published important laws concerning Christian matrimony, and was firm in enforcing clerical morality. There are 17 letters of this pope in Labbe's collection of the councils, vols. vi. and vii. **III.** Born in Syria, succeeded Gregory II. in 731, died in 741. He wrote to the emperor Leo, reproaching him for upholding the iconoclasts; but finding that prince incorrigible, he assembled a council in 732, which excommunicated them as heretics. The

Lombards annoyed him, and in the hope of obtaining the aid of Charles Martel against them he sent an embassy to France, but the application proved fruitless. Gregory was the first pope who ruled the exarchate of Ravenna in a temporal sense, not in virtue of any formal donation, but because, abandoned by the Greeks, the citizens saw no one to whom they could appeal for protection but the bishop of Rome. **IV.** Born in Rome, made pope in 827, died in 844. He rebuilt the city of Ostia, to defend the mouth of the Tiber against the inroads of the Mussulmans who had taken possession of Sicily. He went to France in the hope of putting an end to the dissensions between Louis le Débonnaire and his sons, but failed, and returned to Rome disgusted with both parties. **V. Bruno**, a Saxon, nephew of the emperor Otho II., elected pope in May, 996, died in 999. His pontificate was troubled by Philogethes, bishop of Piacenza, who became antipope under the name of John XVI. The latter was sustained by Crescentius, consul of Rome, but finally driven thence by Otho III., and excommunicated by Gregory in the council of Pavia, 997. Otho was crowned by his cousin in 996. **VI. John Gratianus**, a Roman, and archpriest of the Roman church, elected pope, some say by simoniacal means, April 8, 1045, died in 1047. He resigned at the council of Sutri in December, 1046, and retired to the monastery of Cluny. **VII. Hildebrand, Saint**, born at Soano, Tuscany, about 1018, died in Salerno, May 25, 1085. He was the son of a carpenter, and was educated by his uncle in a Roman monastery. He afterward went to France, and became a monk of Cluny. Recalled to Rome, and made prior of the abbey of St. Paul *extra muros*, he found his church almost in ruins, the community reduced to a few members, and nearly all its lands in the possession of powerful laymen. With an energy which foreshadowed his career, he recovered the lands, restored the church, improved the discipline, and increased the community. He gained the favor of Gregory VI., became the confidential adviser of Leo IX., and preserved his influence under Victor II. and Alexander II. By Gregory VI. he was sent to France in 1045 to urge the extirpation of simony. He had a law passed against it in a council at Lyons, and presided in the council of Tours, in which Berengarius recanted his opinions concerning the eucharist. He was instrumental in effecting the election of Nicholas II. and Alexander II.; and was himself chosen pope on April 22, 1073. It is asserted that he did not seek this elevation, and that he wrote to Henry IV., then in Bavaria, beseeching him to have the election set aside, and giving the emperor warning that if he occupied the papal chair he would call him to account for his tyranny and licentiousness. Henry sent officers to examine into the hasty election, ratified it, and allowed Gregory to be consecrated on June 30. Once enthroned, he resolved to purge the priesthood of the two enor-

mous evils of simony and unchastity, and to emancipate the church from the interference of the temporal power. He wrote to the countess Beatrice and her daughter Matilda to hold no communion with the simoniacal bishops of Tuscany. The emperor, who made no scruple or secret of selling ecclesiastical livings to the highest bidder, both in Germany and Italy, had thus twice disposed of the see of Milan. Gregory deposed the archbishop as an example to offenders, and held a council in Rome, in which it was made a law that all persons guilty of simony should be *ipso facto* excommunicated as incapable of exercising ecclesiastical jurisdiction, and disqualified for holding any benefice whatever. It was furthermore decreed that all married and unchaste priests should be degraded from their office. This legislation produced great excitement throughout Germany, where an attempt to enforce it well nigh cost the archbishop of Mentz his life. It brought the pope into direct collision with the emperor, who traded in benefices. Henry had been summoned to Rome to answer for his tyrannical and licentious conduct; he laughed at the summons, and derided the legates whom Gregory repeatedly sent to bring him to a sense of his wrong doing. In 1075 Cencius, prefect of Rome, had been excommunicated, with several of his abettors, for various crimes. On Christmas eve, while the pope was celebrating midnight mass at Sta. Maria Maggiore, Cencius rushed into the church with a body of armed men, who dragged Gregory from the altar, wounded him in the neck, and hurried him off to a prison. This outrage was attributed by some to the emperor's instigation. The only reply Henry made to the papal summons was to assemble a council at Worms in 1076, which passed a sentence of excommunication against Gregory. Henry informed him of this in a letter addressed "to the false monk Hildebrand," which the imperial messenger handed to the pope at Rome in the midst of the solemn session of the council. A sentence of excommunication was fulminated against the emperor, whose crown was declared forfeited. Saxony and Thuringia had already been driven into open rebellion by the conduct of Henry; on reception of the tidings from Rome, a majority of the princes of the empire and several bishops met near Mentz, and, after vainly summoning Henry to appear and make satisfaction, they elected in his stead Rudolph, duke of Swabia. Abandoned by his adherents, Henry was compelled to sue for pardon, crossed the Alps, and presented himself before the pope, who had taken refuge in the castle of Canossa. Whatever truth there may be in the relations of those who assert that the pontiff kept the suppliant emperor three whole days in the court of the castle, clad in a single garment and shivering in the cold of January, we may well believe that he treated him with severity. Absolved from excommunication, Henry returned, fought his enemies, and re-

gained his crown by the death of Rudolph. The pope in absolving him had not reinstated him in his imperial rank; hence the resistance he met with on his return to Germany, and hence, too, the animosity with which from that moment he pursued Gregory to the death. In 1081 he crossed once more into Lombardy, and assembled a council, which deposed and excommunicated the pope, and elected in his stead Guibert, archbishop of Ravenna, with whom Henry advanced toward Rome, but withdrew at the approach of Robert Guiscard and his Normans. He returned the next year with no better success, but on his third attempt was admitted into Rome by the treachery of some of the citizens. The pope fled to the fortress of Sant' Angelo, and Guibert was enthroned as Clement III.; but Robert hastened by forced marches to the relief of Gregory, and Henry with his antipope withdrew from Rome. The Tuscan forces were victorious in Lombardy over Gregory's enemies, but his health was hopelessly broken. Robert, his deliverer, was unwilling to allow him in his enfeebled state to remain within reach of his persecutors, and persuaded him to rest for a while in Monte Casino, and then to take up his abode temporarily in Salerno, where he died repeating the words, *Dilexi justitiam et odivi iniquitatem, propterea morior in exilio* ("I have loved righteousness and hated wickedness, therefore do I die in exile"). These words may still be read on his tomb in the church of St. Matthew in Salerno. There is a collection of his letters in the Bollandists' *Acta Sanctorum*. See also his epistles in Migne's *Patrologie*, vol. cxlviii.; his life by the German Protestant Voigt; and the posthumous work of Villemain, *Histoire de Grégoire VII.* (2 vols. 8vo, Paris, 1873; English translation by Brockley, London, 1874). **VIII. Alberto de Mora**, succeeded Urban III., Oct. 21, 1187, died Dec. 17 of the same year. He is not to be confounded with the antipope Bourdin, who assumed the name of Gregory VIII. **IX. Ugolino**, succeeded Honorius III. in 1227, died in Rome, Aug. 21, 1241. He is remarkable chiefly for his protracted struggle with the emperor Frederick II. (See **FREDERICK II.** of Germany.) **X. Tebaldo Visconti**, born in Piacenza about 1209, died in Arezzo, Jan. 10, 1276. He became successively canon of Lyons, archdeacon of Liège, and cardinal. He was papal legate in Palestine, when, after an interregnum of three years, he was elected pope Sept. 1, 1271. He opened the second general council of Lyons in 1274, made vain endeavors to rouse Christian princes to succor Palestine, effected a temporary reunion of the Greek and Latin churches, and was the first to enact a stringent law for the holding of conclaves. (See **CONCLAVE.**) Gregory X. was beatified in 1713. **XI. Pierre Roger**, born in Lower Limousin in 1329, elected pope in 1370 (the last Frenchman who has occupied the pontifical chair), died March 27, 1378. To him belongs

the credit of having put an end to what was called the captivity of Babylon, meaning the residence of the popes at Avignon. Yielding to the solicitations of many of the most eminent persons in Christendom, he quitted Avignon in 1376, and returned to Rome at the beginning of 1377. This pope was the first who condemned the teachings of Wycliffe. **XII. Angelo Corario**, born in Venice about 1325, elected pope in 1406, died at Recanati, Oct. 18, 1417. For an account of him see CONSTANCE, COUNCIL OF. **XIII. Ugo Buoncompagni**, born in Bologna, Feb. 7, 1502, elected pope May 13, 1572, died April 10, 1585. Distinguished as a lawyer and professor of civil and canonical jurisprudence, he appeared with success at the great council of Trent. His pontificate is remarkable as the epoch of the reformation of the calendar. (See CALENDAR.) The *Decretum Gratiani* (see CANON LAW) was published by him in splendid style, and with copious notes, some of which were from the pope's own hand. The end of his pontificate was signalized by the appearance in Rome of an imposing embassy from Japan, sent by some of the princes who had been recently converted to the Christian faith. **XIV. Nicolò Sfondrati**, born in Cremona, elected pope Oct. 8, 1590, died in 1591. **XV. Alessandro Ludovisi**, born in Bologna in 1554, elected pope Feb. 9, 1621, died July 8, 1623. He founded the celebrated congregation *de propaganda fide*, a sort of foreign office for the disposing and arranging of ecclesiastical affairs of missionary countries throughout the world. He canonized four celebrated saints of the Catholic church, Ignatius Loyola, Francis Xavier, Philip Neri, and Teresa. He enacted that the balloting for the election of new popes should be done secretly. **XVI. Bartolommeo Alberto Capellari**, born in Beluno, Sept. 18, 1765, died in Rome, June 1, 1846. He assumed the name of Mauro on making his profession in the order of Camaldolese monks in 1783, became proficient in the oriental languages, taught theology with much distinction, published in 1799 *Il trionfo della Santa Sede e della Chiesa*, and in 1801 was elected a member of the academy of the Catholic religion in Rome, where he annually lectured on subjects bearing on the relations between science and revelation. In 1807 he was appointed one of the censors of the academy, and elected vice procurator general of his order, and abbot of his monastery in Rome. In 1809 the violent abduction of Pius VII. was followed by the dispersion of the religious orders. Capellari withdrew to his native country, and taught theology in the monastery of St. Michael at Murano. In his island solitude he remained comparatively quiet till 1812, when the ancient and magnificent library of the monastery was seized, and either sold at auction or sent to enrich the libraries of Venice. In the beginning of 1814 he and his pupils and fellow professors took refuge in Padua. Recalled to Rome after the return of Pius VII.,

he was made procurator general of his order, consultant of the Propaganda, examiner of bishops, commissary for examining works on oriental liturgical literature, and vicar general of the Camaldolese. He was preconized cardinal March 13, 1826, and became prefect of the Propaganda. He was charged soon after with negotiating a concordat with the government of the Netherlands in favor of the Catholic citizens, and with regulating the ecclesiastical affairs of the United States, and obtained from the Turkish government the emancipation of the Armenian Catholics. On Feb. 2, 1831, after 50 days of conclave, he was elected pope. The secret societies which aimed both at Italian unity and at secularizing the administration of the States of the Church, made some insurrectionary movements at the beginning of his pontificate. With Prussia a long controversy arose about mixed marriages, the government claiming to regulate them as belonging solely to the civil administration. The archbishop of Cologne was imprisoned for his resistance, and the pope energetically interfered in his favor. The Catholics of Russian Poland were also subjected to oppression to induce them to join the Greek church; and the pope used no less energy in protesting against this violence through his representative in St. Petersburg. He solemnly condemned the innovations of Hermes in theology, and the extreme political radicalism of Lamennais. He spared no effort to spread the Catholic religion in both hemispheres, and to stimulate at home the zeal of all ranks of the priesthood for the attainment of solid learning and purity of life. In Rome he gave a great impulse to the study of the sciences and fine arts, created several museums, and founded a number of establishments of public beneficence and utility. During the 15 years of his reign he gave hospitality to more than one royal exile. In December, 1845, the emperor Nicholas visited Rome, and during his interview with the pope he was bitterly reproached for his cruelty toward the Poles. It is said that Gregory spoke to him as would one on whom the shadow of death had already fallen, threatening the autocrat with that judgment for which he was himself preparing. The emperor was much moved, and returned again to visit his venerable host. It is certain that the Poles experienced less harsh treatment for some years after that.

**GREGORY. I. James**, a Scottish astronomer and mathematician, born at Drumoak, Aberdeenshire, in November, 1638, died in Edinburgh in October, 1675. He was educated at Marischal college, Aberdeen, and at the age of 24 published his *Optica Promota* (London, 1663), which formed an era in the history of science in the 17th century, and in which he described the reflecting telescope invented by him. In the same work he pointed out the method of employing the transits of Mercury and Venus to determine the sun's parallax. In 1667 he went to the university of Padua, and

soon after published a treatise on the quadrature of the circle and hyperbola by means of a converging series, which involved him in a controversy with Huygens. About 1668 he was chosen professor of mathematics at St. Andrews. In 1674 he accepted the same chair in Edinburgh, and a year later was struck with sudden blindness, and died a few days afterward. He was the inventor of the concave burning mirror, of methods for squaring curves and making logarithms by an infinitely converging series, and of a variety of other ingenious mathematical and geometrical processes. **II. David**, nephew of the preceding, born in Aberdeen, June 24, 1661, died about 1710. He was educated at the university of Edinburgh, where he was appointed professor of mathematics in 1684, and was instrumental in introducing the Newtonian philosophy. In the same year he published a Latin treatise on the dimensions of figures, *Exercitatio Geometrica*, which is esteemed his best work. In 1692, chiefly through the influence of Flamsteed and Sir Isaac Newton, he was appointed Savilian professor of astronomy at Oxford, the celebrated Dr. Halley being his competitor. In 1702 appeared his *Astronomia Physicæ et Geometriæ Elementa*, a sort of digest of Newton's *Principia*, which Newton himself highly commended; and in 1703 he published an edition of Euclid in Greek and Latin. He was engaged at the time of his death upon an edition of Apollonius, which was completed by Halley. Newton intrusted Gregory with a manuscript copy of his *Principia*, and in a second edition availed himself of his friend's marginal comments. **III. John**, grandson of James Gregory, born in Aberdeen, June 3, 1724, died in Edinburgh, Feb. 10, 1773. He graduated in medicine at the university of Aberdeen, where he filled the chair of medicine from 1756 to 1764, when he removed to Edinburgh. From 1766 till his death he was professor of the practice of physic in the university of Edinburgh. His principal works are "Elements of the Practice of Physic" (Edinburgh, 1772), left unfinished, and "A Father's Legacy to his Daughters" (1774).

**GREGORY, Olinthus Gilbert**, an English mathematician, born in Yaxley, Huntingdonshire, Jan. 29, 1774, died in Woolwich, Feb. 2, 1841. He wrote a treatise on the "Use of the Sliding Rule," a "Treatise on Astronomy," and in 1802, in connection with Dr. John Mason Good, undertook to edit the "Pantologia," a cyclopædia of the arts and sciences. He was appointed a mathematical master at the royal military academy at Woolwich, and in 1806 was raised to the professor's chair, which he held till June, 1838. His principal works are a "Treatise on Astronomy," a "Treatise on Mechanics," the "Evidences of Christianity," and "Memoirs" of the Rev. Robert Hall and Dr. John Mason Good.

**GREGORY THE ILLUMINATOR**, a saint of the church, the apostle and first patriarch of Ar-

menia, born in 257, died about 332. He was the son of Anag, a prince of the royal family of the Arsacidæ, who having assassinated Chosroes, king of Armenia, was put to death with all his family except Gregory, then two years old. Gregory was taken to Cæsarea in Cappadocia by a Christian nurse, and on becoming of age was there married, but separated from his wife three years later by mutual consent. He went to Rome, attached himself to the suite of Tiridates III., king of Armenia, and accompanied him to that country, where, having refused to sacrifice to idols, he was subjected to various tortures, and finally cast into a dungeon near Artaxata. A benevolent widow supported him here for 14 years. At the end of that time the king, who is said to have been cured by his prayers of a desperate malady, embraced the faith (302). The saint afterward went to Cæsarea, and was consecrated metropolitan of Armenia. Returning to that country, he preached the gospel both E. and W. of the Euphrates, baptized many, destroyed pagan temples, built churches, ordained priests, and, having converted most of the nation, consecrated his son Arisdages as his successor in 318. In 325 he and the king were invited by Constantine to the council at Nice. In 331 he withdrew into a cavern, where he died.

**GREGORY NAZIANZEN**, a saint and doctor of the church, born about 328, died about 389. His father Gregory, a convert from heathenism, was on account of his holy life and great zeal made bishop of Nazianzus in Cappadocia, which see he governed 45 years, and died when about 90 years old. He and Nonna, the mother of the saint, are recognized as saints in the calendars of the church. The son was carefully educated in the schools of Cæsarea, Alexandria, and Athens, and had for fellow students Basil the Great, Gregory of Nyssa, and Julian the Apostate. At his return to Nazianzus he was baptized, and lived austere as a hermit in company with St. Basil. After some time thus spent in study and religious exercises, he was recalled to Nazianzus, was ordained priest, and assisted his father in the government of his diocese. He fled again for a time to the desert, but fearing to incur the displeasure of heaven by shrinking from his work, he returned to Nazianzus, and on Easter Sunday preached his first sermon. He is considered by many as the most eloquent of all the fathers of the church. His addresses are fervid, florid, and fanciful, for Gregory was a poet, and wrote much in verse as well as in prose. Among his early discourses were two of great severity against the emperor Julian. In 372 he was consecrated by St. Basil bishop of Sasima; but being prevented from occupying that see, he remained to help his father at Nazianzus. In 378 the death of the emperor Valens restored peace to the church, and the pastors everywhere sought to revive in their churches their pristine glory, obscured by 46

years of Arian domination. Some of the principal sees were in a deplorable condition, and in Constantinople especially the Christians were without a pastor, or even a place where they might assemble for worship. Gregory was living in retirement at Seleucia, but many of the bishops desired to place him in the episcopal chair of Constantinople. He finally yielded to their joint entreaties and appeared upon his new field of labor. His lowly and penitential exterior made an unfavorable impression upon the citizens of the proud and wealthy capital of the East. The Arians and Apollinarists derided, and even pelted him with stones. Still his great patience and zeal acted favorably upon the people, aided, as we are told, by several miracles. Many were converted from paganism, heresy, and dissolute lives through his eloquence and learning. Gregory, however, soon became weary of the growing cares of his great see; and although the emperor Theodosius and Pope Damasus and the bishops supported him against his persecutors, especially against an intruded bishop named Maximus, and although even a council called at Constantinople declared him patriarch, he insisted upon resigning all his honors, and retired again to Nazianzus, and withdrew from thence to a solitary abode near Arianzus. Worn out by age and unremitting austerities, he died in his retreat. The Latins honor him on May 9. His ashes were conveyed from Nazianzus to Constantinople, and thence during the crusades to Rome, where they repose under an altar inscribed to his memory in the Vatican church. His works consist chiefly of 55 sermons, 235 letters, and 158 pieces of poetry. Twenty poems are to be found in Tollius, *Insignia Itinerarii Italici* (4to, Utrecht, 1696), called by the editor *Carmina Cygnea*. Muratori published 228 unedited epigrams of Gregory's in his *Anecdota Græca* (Padua, 1709). The principal editions of his works are those of Basel, fol., 1550, with life by Suidas and by Gregory the Presbyter; De Billy, 2 vols., Paris, 1609-11; the Benedictine Dom Maran, Paris, 1788 (only vol. i.; vol. ii., Paris, 1840, edited by the Benedictine Caillau); and vols. xxxv. to xxxviii. of Migne's *Patrologie grecque*, Paris, 1856-'66 (Greek text with Latin translation). A selection of his works was published by Goldhorn (Leipsic, 1854). See Ullmann's *Gregorius von Nazianz* (Darmstadt, 1825), and Villemain, *Tableau de l'éloquence chrétienne au quatrième siècle* (Paris, 1846).

**GREGORY OF NYSSA**, a saint and father of the church, born in Cappadocia about 331, died about 400. He was a younger brother of Basil the Great, studied with him at Athens and Constantinople, was married, then embraced the ecclesiastical profession, and was ordained lector. Yielding to his passion for literature, he opened a school of eloquence, but was induced by Gregory Nazianzen to dedicate his talents to the ministry. In 370 he became assistant to his brother at Cæsarea, and in 372

was chosen bishop of Nyssa. He was exiled under Valens by the Arians, was deputed in October, 379, by the council of Antioch, to visit the churches of Palestine and Arabia, was present at the council of Constantinople in 381, and again in 382 and 383. Gregory of Nyssa's works contain the most complete philosophical exposition of Christian dogma given before St. Augustine. He follows Origen in his scientific methods, combats expressly his heterodox theorems, and has been accused of leaning toward his theory of the final salvation of all beings. His works were published in part by Sifanus (Basel, 1562-'71); by the Jesuit Fronton du Duc (2 vols., Paris, 1615; vol. iii. edited by Claude Morel in 1638); and by Migne (*Patrologie grecque*, vols. xlv.-xlvii., Paris, 1857-'66). A selection of his works is found in Ohler's *Bibliothek der Kirchenväter*, vols. i.-iv. (Leipsic, 1858).

**GREGORY THAUMATURGUS** (the wonder worker), a saint of the church, born in Neo-Cæsarea about 210, died there about 270. He is also called Gregory of Neo-Cæsarea. He was educated a pagan until his 14th year, studied the law at Alexandria and Athens, and in 234 entered the school of Origen at Cæsarea, where he remained for five years. He was chosen first bishop of his native city at a time when it only numbered 17 Christians; but, according to historians, he labored so faithfully that at his death only 17 pagans were to be found in his place. Gregory of Nyssa, his biographer, relates from the local traditions the miracles said to have been wrought by him, and which obtained him his surname. His feast is celebrated in the Latin church on Nov. 17. His works, which contain "A Panegyric Oration on Origen" and "A Paraphrase on the Book of Ecclesiastes," are found in vol. x. of Migne's *Patrologie grecque*. See also Eusebius, "Ecclesiastical History," books vi., vii.

**GREGORY OF TOURS** (GEORGIUS FLORENTIUS GREGORIUS), a saint of the Roman Catholic church, born in Auvergne about 540, died in Tours probably on Nov. 17, 595. He is called the father of French history, was descended from a senatorial family, and educated under St. Gall, bishop of Clermont. In 573 he was elected bishop of Tours; and in 575 he refused to surrender Duke Gontran, who had sought an asylum in the church of St. Martin, to Chilperic and Fredegonda. For this his property was confiscated and his diocese laid waste. Later, Chilperic's son Meroveus having taken refuge there, the king besieged the city of Tours; but Gregory would not give up the fugitive. After the assassination of Chilperic, Gregory displayed on many occasions the same intrepidity in vindicating the rights of the oppressed. In 587 he negotiated the treaty of Andelot between Childebert, Brunehaut, and Gontran, which gave a brief peace to France. His complete works were published by Dom Ruinart (fol., Paris, 1699); and a translation of his *Historia Francorum* by Guizot (2 vols.,

1859; 2d ed., 1863). His life, written in Latin by Odo, abbot of Cluny, in the 10th century, is given by Baillet in his *Vies des saints*.

**GREIFSWALD**, or **Greifswalde**, a town of Pomerania, Prussia, on the river Ryck, 3 m. from the sea and 20 m. S. E. of Stralsund; pop. in 1871, 17,208. It was once a place of considerable strength, and is still surrounded by a wall, which has been converted into a promenade. It contains a university founded in 1456, which in 1873 had 57 professors and 537 students. Connected with the university is an academy of political economy and agriculture at Eldena. There are also several high schools. The town has manufactories of pins, soap, candles, tobacco, and leather.—Greifswald was founded in the 13th century, soon became flourishing, and was conspicuous as a member of the Hanse league. In the thirty years' war it was taken from Bogislas, duke of Pomerania, by the imperialists under Wallenstein, and soon after (1631) by the Swedes, who were confirmed in its possession by the peace of Westphalia. It afterward often changed masters, being finally annexed to Prussia in 1815.

**GREINER, John**, an American journalist, born in Philadelphia, Sept. 14, 1810, died in Toledo, O., May 13, 1871. He early became prominent in Ohio as a whig politician, and in the presidential canvass of 1840 wrote "Old Zip Coon," "The Wagoner Boy," and other popular electioneering songs. He was also distinguished as a temperance lecturer. He was state librarian of Ohio from 1845 to 1851, when he was appointed Indian agent for New Mexico, and in 1852 was governor of that territory. He was afterward successively local editor of the "Ohio State Journal," and editor and proprietor of the Columbus "Gazette" and the Zanesville "Times." In 1861 he was appointed receiver of the land office at Santa Fé, and in 1862 sub-treasurer there, which office he held till 1866.

**GREIZ**, a town of Germany, capital of the senior princes of Reuss, on the right bank of the White Elster, near the Saxon border, 49 m. S. S. W. of Leipsic; pop. in 1871, 11,582. It contains an imposing château, with a summer palace, an ancient castle on the adjoining Felsberg, several churches, and a new town hall. Woollen and half-woollen goods (employing 3,000 looms) and many other articles are made here, and about 70 manufacturers of Greiz attend the annual fairs at Leipsic.

**GRELLET, Stephen**, a Quaker missionary, born in France in 1773, died in Burlington, N. J., Nov. 16, 1855. He was originally a Catholic, and was educated at the military college of Lyons. At the age of 17 he entered the body guard of Louis XVI., after whose execution he escaped to Demerara. In 1795 he went to New York, where, chancing to attend a Quaker meeting, he determined to join that society. In the following winter he removed to Philadelphia, and during the prevalence of the yellow fever there in 1798 he ministered to

the sick, the dying, and the afflicted. In 1799 he removed to New York and engaged in mercantile business. Becoming impressed that it was his duty to go forth as a missionary, he made a tour into the southern states in 1800, and in 1801 into New England and Canada. In 1807 he visited the south of France, and in 1812 travelled in England and Germany. In 1816 he preached to the inhabitants of Hayti, and in 1818 and the two following years he travelled through Norway, Sweden, Russia, Greece, and Italy, having an audience of the czar, and preaching before the pope. He returned to New York in 1820, and again travelled through Europe from 1831 to 1834, when he retired to Burlington.—See "Memoirs of Stephen Grellet," edited by B. Seeböhm (Philadelphia, 1868).

**GRENADA**, a British colony and island in the West Indies, the most southerly of what are called the Caribbee islands, between lat. 11° 58' and 12° 20' N., and lon. 61° 40' and 61° 55' W., about 90 m. from the nearest part of South America; length from N. to S. about 24 m., greatest breadth 12 m.; area, 133 sq. m.; pop. in 1871, 37,684, about one tenth of whom were whites. A range of mountains, whose highest peak, Mt. St. Catharine, is 3,200 ft. above the sea, traverses the whole length of the island, with outliers of less elevation. Numerous small rivers rise in these mountains, the principal of which are the Great Bucculet, Duquesne, Antoine, St. John's, and Beau Séjour. In the centre of the island, and 1,700 ft. above the sea, is a circular lake 2½ m. in circumference. The island is divided into six districts called parishes. The capital, St. George (pop. 5,000), is on the S. W. coast, near a large and strongly fortified bay, which is capable of giving shelter to a large fleet of first class vessels. It is nearly landlocked, and steamers of 1,800 tons can lie alongside the wharves. This port is a coal depot and central station for the British West India mail steamers. Grenada is governed by a lieutenant governor, a council of 12 members, and a legislative assembly of 17. The revenue in 1870 was £23,106, the expenditure £20,824; the public debt in 1869 was £7,000. The imports in 1870 were in value £104,475, and the exports £127,184. The staple products of the island are sugar, rum, molasses, and cacao of a superior quality. Among the minor articles of export are yams, charcoal, and arrowroot. The Grenadines are four small islands in the vicinity of Grenada, the largest of which, Carriacou, is 7 m. long and 2½ m. broad; total pop. 3,000.—Grenada was discovered by Columbus in 1498, and was at that time peopled by the fierce and warlike Caribs. In 1650 the first European settlement was made by Du Parquet, the French governor of Martinique, who landed with 200 followers, and speedily conquered the island and massacred the natives. In 1762 it was conquered by the British, from whom it was retaken by the French in 1779, and by them restored to Great

Britain at the peace of 1783. Slavery was completely abolished in 1838, at which time the slaves numbered 17,190, and the free population 3,804, most of whom were colored.

**GRENADA**, a N. county of Mississippi, intersected by Yallabusha river; area, about 400 sq. m.; pop. in 1870, 10,571, of whom 6,642 were colored. The surface is level, and the soil fertile. It is traversed by the Mississippi and Tennessee and the Mississippi Central railroads. The chief productions in 1870 were 191,675 bushels of Indian corn, 19,548 of sweet potatoes, and 6,479 bales of cotton. There were 832 horses, 1,108 mules and asses, 1,976 milch cows, 4,484 other cattle, 2,059 sheep, and 9,419 swine; also, 2 saw mills. Capital, Grenada.

**GRENOBLE** (anc. *Cularo* or *Gratianopolis*), a fortified city of France, capital of the department of Isère, on both sides of the river Isère, 58 m. S. E. of Lyons and 290 m. S. E. of Paris; pop. in 1872, 42,660. The old part

Grenoble.

of the city, called the faubourg St. Laurent, is on the N. bank of the river, and is connected with the modern quarter on the opposite bank by two bridges. The church of Notre Dame, the episcopal palace, a hospital, several convents, halls of justice, a theatre, arsenal, and citadel are admired. There is a public garden, a normal school, schools of design and of architecture, a college, a public library of 80,000 volumes and 1,200 MSS., a museum, a cabinet of natural history, manufactories of kid gloves (which alone employ several thousand hands), liqueurs, leather, &c., and a trade in hemp, iron, and marble. The city was called *Gratianopolis* in honor of the emperor Gratian in the 4th century, and its present name is a corruption of that word. It was afterward the capital of Dauphiny.

**GRENVILLE**, an E. county of Ontario, Canada, bordering on the St. Lawrence, and bounded N. by the Rideau river and canal; area, 463 sq. m.; pop. in 1871, 22,616. It is well watered, and is traversed by the Grand Trunk and the St. Lawrence and Ottawa railroads. Capital, Prescott.

**GRENVILLE**, *George*, an English statesman, the reputed author of the famous stamp act, born Oct. 14, 1712, died Nov. 24, 1770. He was chosen to parliament in 1741, and continued a member till the time of his death. In 1762 he was made successively secretary of state and first lord of the admiralty. In 1763 he was appointed chancellor of the exchequer and first lord of the treasury; but in 1765 he resigned the premiership, giving place to Lord Rockingham. He was an eloquent speaker and an able man of business.

**GRENVILLE**, *Richard*. See **TEMPLE**, **EARL**.

**GRENVILLE**, *Greenville*, or *Granville*, **Sir Richard**, an English naval officer, born in the west of England in 1540, died at sea in 1591. He was nearly related to Sir Walter Raleigh. At the age of 16 he served in the German imperial army as a volunteer against the Turks. On his return he was appointed to a command in Ireland, and was made sheriff of Cork. In 1571 he represented Cornwall in parliament, and afterward, being made high sheriff of that county, was knighted by Queen Elizabeth. He entered with ardor into Raleigh's schemes of colonization in America, and in 1585 commanded the fleet of seven vessels carrying 108 colonists which Raleigh despatched to Carolina, sailing from Plymouth April 9. The fleet touched at the Canaries and at the West Indies, where it captured two Spanish frigates, and on June 20 made the mainland of Carolina, or Florida, as it was then called. It narrowly es-

caped wreck on the cape to which Greenville, in consequence, gave its present name of Cape Fear. It anchored at Wocoken June 26, and passing through Ocracoke inlet made its way to Roanoke. Greenville with a party explored the country for eight days, and in revenge for the theft of a silver cup burned an Indian village and destroyed the standing corn. In August, leaving the colonists under command of Ralph Lane, he sailed for England. On his way home he took a rich Spanish vessel, and was received at Plymouth with high honors, Sept. 18. The next year he recrossed the Atlantic with three ships laden with supplies, but found his colony broken up and the settlers gone. They had departed about three weeks before in a fleet commanded by Sir Francis Drake, who on his way home from the West

Indies had paid them a visit, and found them tired of their situation. Grenville, to keep possession of the country, left 15 men on Roanoke island, and sailed again for England. In 1588 he was made a member of the council created to devise means of defence against the Spanish armada, and in 1591 was raised to the rank of vice admiral and sent with five ships to cruise against the Spaniards in the West Indies. Off the Azores he encountered a Spanish fleet of 53 ships with 10,000 men on board. He gave them battle at 3 P. M., fought them till daybreak, and beat them off 15 times. Four of the Spanish ships sank during the action or soon afterward, and 1,000 Spaniards were killed. Grenville was wounded early in the fight, but refused to go below, and had his wounds dressed on deck. At length he was shot through the body, and was carried into his cabin, upon which the remnant of his crew surrendered. He was taken on board a Spanish ship and well treated, but died in three days.

**GRESHAM, Sir Thomas**, an English merchant, born in London in 1519, died there, Nov. 21, 1579. He was educated at Cambridge, became a London merchant, and was employed in 1551 in negotiating foreign loans for the government of Edward VI., and subsequently for those of Mary and Elizabeth; and he suggested to the latter the advantage of raising loans from her own subjects rather than from foreign states. He accumulated immense wealth, and was the founder of the first royal exchange, and of Gresham college. By his will his London residence was vested in trustees, who were to see that seven able lecturers, each with a salary of £50 per annum, payable from the rents of the exchange, and having apartments in the mansion, were elected to deliver lectures there on divinity, astronomy, music, geometry, law, physic, and rhetoric. In 1768 the building was sold to government, and the character of the institution modified by act of parliament; the lectures were subsequently read at the royal exchange until it was burned in 1838, and in 1843 the present college was opened.

**GRESLON, Adrien**, a French missionary in Canada and China, born at Périgueux in 1618, died in 1697. He came to America in 1647, and, after seeing the Huron mission destroyed and many of his fellow missionaries put to death by the Iroquois, returned to Europe in 1650. He went to China in 1657, and remained there till 1670. While in Chinese Tartary he is said to have met an Indian woman whom he had known on Lake Huron, and who had been sold from tribe to tribe. This led to the belief that America and Asia approached each other very nearly.

**GRESSET, Jean Baptiste Louis**, a French author, born in Amiens in 1709, died in 1777. He was educated at a college of the Jesuits, and at the age of 16 entered the order as a novice. In 1733 he published a poem under the title of *Vert-vert*, in which he ridiculed some of the features of convent life. Having removed to

Paris, he produced successively *La Chartreuse*, *Le carême impromptu*, *Le lutrin vivant*, and *Les ombres*, all of which were received with great favor on account of their spirited style and elegant versification. But the freedom of some of his remarks displeased his religious superiors, and he left the order before the end of his novitiate. He now produced a tragedy, *Édouard III.*, and a few years later *Sidney*, a drama. In 1747 appeared his comedy of *Le méchant*, which procured him admission to the French academy. In the midst of his successes Gresset retired to Amiens, where having married he passed his time in religious employments, in the care of his family, and in attacking various abuses. He condemned the irreligious tendency of his works, committed several unpublished pieces to the flames, and asked pardon of heaven in a copy of verses which Voltaire and Piron ridiculed. He founded an academy of letters at Amiens, and, as director of the French academy, was chosen to congratulate Louis XVI. and Marie Antoinette on their accession to the throne in 1774; in return for which he received a patent of nobility. An edition of his works in 3 vols. was published at Paris in 1811. *Vert-vert* has repeatedly been translated into English.

**GRESWELL, Edward**, an English ecclesiastical writer, born in Manchester in 1797, died in Oxford, June 29, 1869. After graduation at the university, he became fellow and vice president of Corpus Christi college, and devoted himself to theological literature. His works are valuable and highly esteemed by scholars. Among them are: "Exposition of the Parables and other Parts of the Gospels" (5 vols. 8vo, 1834-'5; *Prolegomena ad Harmoniam Evangelicam* (4th ed., 1845); "Dissertations upon the Principles and Arrangement of a Harmony of the Gospels" (5 vols., 2d ed., 1837); *Fusti Temporis Catholici* (5 vols., with tables, 1852); and *Origines Kalendarie Italiane* (4 vols., 1854), showing the early calendars of Romulus, of Numa Pompilius, and of the de-cemvirs. He also translated into Greek verse Milton's "Comus" and "Samson Agonistes."

**GRETCH, Nikolai**, a Russian author, born in St. Petersburg, Aug. 14, 1787, died there, Jan. 24, 1867. He acquired eminence as a teacher, and became councillor of state in 1829, and privy councillor in 1862. His best known work is a manual of Russian literature (4 vols., St. Petersburg, 1819-'22).

**GRETNA GREEN**, a small village of Dumfriesshire, Scotland, 9 m. N. W. of Carlisle, famous for the celebration of irregular marriages until December, 1856, from which date, by the act passed July 29, such marriages were declared invalid, unless one of the parties had been for 21 days a resident of Scotland. The ceremony consisted in an admission before witnesses by the parties that they were husband and wife, this being sufficient, according to the law of Scotland, to constitute a valid marriage. After the ceremony, the officiating functionary (who

was often a blacksmith) signed a certificate of marriage, which was also signed by two witnesses, and then the union became perfect and indissoluble. When they were English, the marriage service of the church of England was sometimes used. The number of these marriages celebrated at Greta and the other border villages has been said to have averaged about 500 a year.

**GRÉTRY, André Ernest Modeste**, a French composer, born in Liège, Feb. 8, 1741, died at Montmorency, near Paris, Sept. 24, 1813. At six years of age he was placed in the choir of the cathedral at Liège, was subsequently instructed in music by some of the masters of the place, and at 18 went to Rome, where he pursued his studies for eight years. Going to Paris, he encountered many disappointments, and was on the point of leaving the city in despair when Marmontel's libretto, *Le Huron*, founded on Voltaire's tale, was put into his hands. In a few weeks the music was ready, and the first performance of the opera raised Grétry to the first rank of composers. It was followed by *Lucile*, *Zémire et Azor* (successfully produced upon the English stage under the title of "Selima and Azor"), *Céphale et Procris*, *Richard Cœur de Lion*, *Barbe-Bleue*, and many others, both serious and comic; and for nearly 40 years Grétry enjoyed a popularity in France which the efforts of rival composers could never impair. Sixteen years after his death (1829) his *Guillaume Tell* was produced in Paris with great care, and evoked such enthusiasm that the composer's bust was brought upon the stage attended by the principal singers, who crowned it with laurels. His principal operas are full of grace and spirit, and the music is melodious and dramatic. The authors of his librettos were in nearly every instance men of genius, which will in a measure account for the uniform success of his works. He was one of the principal founders of the French comic opera. In 1780 he published *Essais sur la musique* (3 vols. 8vo).

**GREUZE, Jean Baptiste**, a French painter, born at Tournus, Burgundy, in 1726, died in Paris, March 21, 1805. He began as a portrait painter; failing in which, he devoted himself to pictures of *genre*. His first works in this class, "A Father explaining the Scriptures to his Family," and "The Paralytic Father," gained him admission to the academy as an associate. For this occasion he painted a historical piece, "Severus reproaching his son Caracalla," which the academy refused to notice, declaring that his admission was wholly due to his merit as a painter of *genre*. Greuze was ambitious to become a historical painter, and went to Rome to study the old masters; but he soon returned to his former style, in which to the end of his career he enjoyed a great reputation. His pictures are highly prized by collectors, and command enormous prices. Among the most celebrated are "The Blind Man Cheated," "The Village Bride," "The Broken Pitcher,"

"The Unnatural Father," and "The Little Girl and the Dog;" the last is by many considered his best picture. These and many others have been repeatedly engraved.

**GREVILLE, Sir Fulke** (Lord Brooke), an English statesman, born in Warwickshire in 1554, died in London, Sept. 30, 1628. He studied both at Cambridge and Oxford. In 1597 he was knighted, and for several years represented his native county in parliament. In 1615 he was made under treasurer and chancellor of the exchequer, and in 1620 became Baron Brooke. His death was caused by a wound received from an enraged domestic who did not consider his services adequately rewarded. He was the author of several works, including "Life of the renowned Sir Philip Sidney" (1652); "A Treatise of Human Learning, in 15 stanzas;" "A Treatise of Warres, in 68 stanzas;" two tragedies, letters, minor poems, &c. There are two collections of his writings: "Certaine Learned and Elegant Workes of Rt. Hon. Fulke Lord Brooke, written in his Youth and familiar Exercise with Sir Philip Sidney" (fol., 1633); and "Remains of Sir Fulke Greville, Lord Brooke" (8vo, 1670). "The Five Years of King James" (4to, 1643), which bears his name, is probably not authentic.

**GRÉVY, François Paul Jules**, a French politician, born at Mont-sous-Vaudrez, Jura, Aug. 15, 1813. He became an advocate at Paris, and acquired influence as an opponent both of socialism and of Bonapartism, and after the February revolution was a member and vice president of the constituent and legislative assemblies from 1848 till Dec. 2, 1851. In 1848 he proposed that the executive should be chosen by the national assembly, and hold office at its pleasure, with the title of president of the council of ministers. In 1868 he was named *bâtonnier* of the order of advocates. He was elected to the corps législatif in 1868 and 1869, and in 1871 to the national assembly by three departments, taking his seat for that of Jura, his old constituency. He was president of the assembly from March, 1871, to April, 1873; but declined the invitation of President Thiers to serve longer in that capacity. He published in 1873 *Le gouvernement nécessaire*.

**GREW, Nehemiah**, an English physician, born in Coventry about 1628, died in London, March 25, 1711. He was the first Englishman who studied vegetable anatomy and physiology, and was elected in 1677 secretary of the royal society. His principal works are: "The Anatomy of Plants, with an Idea of the Philosophical History of Plants" (fol., 1682); "Cosmologia Sacra, or a Discourse of the Universe as it is the Creature and Kingdom of God" (fol., 1701); and "A Catalogue and Description of the Natural and Artificial Rarities belonging to the Royal Society."

**GREY**, a W. county of Ontario, Canada, bounded N. E. by Georgian bay and Owen sound, and watered by Saugeen river and smaller streams; area, 1,800 sq. m.; pop. in

1871, 59,395, of whom 23,511 were of Irish, 17,551 of Scotch, 11,283 of English, 4,702 of German, and 426 of French origin. The land is rough, sandy, and stony, but supports a valuable growth of pine. The county is intersected by the Toronto, Grey, and Bruce railway. Capital, Owen Sound.

**GREY, I. Charles**, earl, an English statesman, born at Fallowden, Northumberland, March 13, 1764, died at Howick house, July 17, 1845. He entered parliament as member for Northumberland in 1786, and attached himself to the whig party, then under the leadership of Fox. In 1788 he was appointed one of the managers of the trial of Warren Hastings. In 1792 he was one of the founders of the "Society of the Friends of the People," whose object was to obtain a reform in parliament. About this time he attempted to mitigate the law of imprisonment for debt. Being in opposition, he was unsuccessful in his endeavor to obtain a committee of inquiry into the conduct of ministers, in his plan of parliamentary reform, and in his proposal to abolish a number of Irish rotten boroughs. Pitt having died in 1806, a new ministry was formed under Lord Grenville, and Grey, now Baron Howick, was appointed first lord of the admiralty, Fox being secretary for foreign affairs. Fox dying in September, Grey took his place. Lord Grenville and he were now the recognized leaders of the whig party, Grenville in the house of lords and Grey in the commons. During this session Grey carried through the bill for the abolition of the slave trade, and moved the abolition of the oath which excluded Roman Catholics from rank in the army and navy. His proposal was met with violent opposition by the Protestant interest, and the king exacted from his ministers a written pledge that they would not press a measure which he considered perilous to church and state. Grey declined to give such a promise, resigned, and the cabinet was broken up. The death of his father in the succeeding year called him as Earl Grey to the house of lords. For the 18 years succeeding the death of Perceval (1812-'30) Earl Grey ably led the opposition. The chief events of his career during this period were his opposition to a renewal of the war in 1815; his condemnation of the coercive measures of the government against the people in the depression and restlessness which followed the peace; his opposition to every attempt to abridge the right of public meeting, and to the bill of pains and penalties against Queen Caroline; his support of Huskisson's measures of commercial reform; and his vehement hostility to Canning's administration. He had the satisfaction in 1829 of seeing the Catholic emancipation act passed. The French revolution of 1830 and other causes having given a new impulse to the agitation for reform, the tory ministry under Wellington was obliged to retire, and William IV. requested Earl Grey to form a government;

he consented only on condition that the reform of the parliamentary representation should be brought forward as a cabinet question. In November, 1830, the new premier announced in the house of lords that the policy of his administration would be "peace, retrenchment, and reform;" and in March, 1831, the first reform bill was introduced. On May 7, 1832, a motion having been carried which was considered hostile to the reform measure, the ministry resigned, and the duke of Wellington undertook to form a new administration. On May 17, however, Earl Grey returned to power; on June 4 the reform bill passed the house of lords, and three days afterward it received the royal assent. He resigned in July, 1834, in consequence of Irish difficulties. **II. Henry George**, earl, an English statesman, son of the preceding, born Dec. 28, 1802. He entered parliament in 1826. On the formation of the reform ministry by his father in 1830, Lord Howick, as he was then called, was appointed under secretary for the colonies, but resigned in 1833 in consequence of his disapproving the details of the measure for negro emancipation. For a few months of 1834 he was under secretary for the home department. He was secretary at war in the Melbourne administration from 1835 to 1839. When the Peel administration came in, he earned the reputation of being one of the most brilliant men of the opposition. On his father's death, in July, 1845, he took his seat in the house of lords as Earl Grey, and in the succeeding year was appointed secretary for the colonies in the administration of Lord John Russell. On his retirement with his colleagues in 1852, he published in two volumes a defence of his colonial policy, and in 1858 an "Essay on Parliamentary Government as to Reform" (2d ed., 1864).

**GREY, Sir George**, a British author, born at Lisburn, Ireland, in 1812. He was educated in the military college at Sandhurst. In 1837, being then a captain, he asked and received permission to explore the interior of Australia. In 1838, with another expedition, he explored the Swan river district. He returned to England in 1840, and in 1841 was appointed governor of South Australia, in 1846 of New Zealand, in 1854 of Cape Colony, and in 1861 again of New Zealand. He returned to England in 1867. He has published "Journals of Two Expeditions of Discovery in N. W. and W. Australia" (2 vols., London, 1841); "Polynesian Mythology and Ancient Traditional History of the New Zealand Race" (1855); and "Proverbial Sayings of the Ancestors of the New Zealand Race" (1858). He possessed a celebrated library, especially rich in geographical and ethnological works. Dr. H. J. Bleck published in 1859 a critical list of the works on African and Polynesian languages.

**GREY, Lady Jane**, a noble English lady, born at Bradgate, her father's estate in Leicestershire, in 1537, beheaded in the tower of London, Feb. 12, 1554. She was the great-grand-

daughter of Henry VII., whose daughter Mary, the young widow of Louis XII. of France, became the wife of Charles Brandon, duke of Suffolk. Their daughter, Lady Frances Brandon, was married to Henry Grey, marquis of Dorset, afterward duke of Suffolk. Lady Jane was the eldest of three daughters of this pair, who had no male issue. She suffered much rigorous treatment in childhood. Her remarkable talents early displayed themselves, and her parents placed her under the tutorship of John Aylmer, afterward bishop of London. At the age of 15 she spoke and wrote Greek, Latin, Italian, and French, with ease and correctness; she had also some knowledge of Hebrew, Chaldee, and Arabic. To these accomplishments (not entirely unusual to young ladies of the period) were added sweetness of disposition and piety of heart. Edward VI. was disposed to bequeath his crown to her in consequence of his aversion to the Catholic principles of his sister Mary, and of the impossibility of excluding this sister on the plea of illegitimacy, without also excluding Elizabeth on the same ground. The duke of Northumberland, knowing Edward's disposition, effected a marriage between Lady Jane and his own son, Lord Guilford Dudley. His machinations were otherwise so successful that Edward gave his final consent to the succession of the bride. Royal letters patent were signed and sealed, excluding Mary and Elizabeth, whose rights were affirmed by the will of Henry VIII., and settling the crown upon the heirs of the duchess of Suffolk. The king's health, which had languished for a year, from this time rapidly declined, his physicians being dismissed, and the royal patient committed to a creature of Northumberland. The duke did not communicate his plan to his daughter-in-law until July 10, 1553, four days after the king's death, when he visited her at Sion House, and approached her with the ceremony usual to royal state. She accepted the crown with great reluctance, yielding only to the entreaties of her husband and father. It was the custom that the first days of a new reign should be passed by the sovereign in the tower of London. Lady Jane Grey was accordingly conducted thither. She was proclaimed queen, but without the slightest manifestation of welcome by the people. Northumberland and Suffolk were so disliked that not even the horror with which the princess Mary was regarded by the Protestant party could diminish the popular ill feeling toward them. Mary had taken refuge with her friends in the north, and as soon as Edward's death was known the Catholics rose to her support in all directions, and she soon approached London with 12,000 men. The most considerable nobles and gentry declared for her without delay; and the duke of Suffolk, who had been appointed by Northumberland to command the army, could bring but little over 6,000 troops into the field. Northumberland, seeing the danger, and losing

all confidence in Suffolk, hastened to take the command in person. His departure from London was the signal for a general desertion of the cause. The mayor and council proclaimed Queen Mary. Even Suffolk deserted his hapless daughter, who, after the vain pageantry of ten days of royal state, would willingly have withdrawn to her private abode. Mary entered the capital in triumph. Northumberland, falling upon his knees, begged abjectly for life, but was executed with two of his most active adherents, Sir Thomas Palmer and Sir John Cate. Suffolk was set at liberty, and the queen would not consent to the death of Lady Jane, though urged by her ministers to do so. Sentence, however, was pronounced against her and her husband, without any immediate intention of putting it into execution, and they were confined in the tower. But in consequence of Wyatt's insurrection, in which Suffolk was mad enough to engage, Mary signed a warrant for their execution on Feb. 8, 1554. Dudley was beheaded on Tower hill; Jane, on account of her royal blood, was allowed to suffer within the precincts of the tower. She met her fate with calmness and piety, refusing to take leave of her husband, whom she hoped that day to meet in heaven.

**GREYHOUND** (*canis venaticus*), a species of dog characterized by a narrow and sharp head, a nose greatly prolonged, and with its plane passing with little elevation nearly to the occiput, long neck, deep chest, arched loins, abdomen much drawn up, and buttocks elevated; the stature is high on account of the elongated and slender limbs; the ears are small, pointed, and semi-pendulous; the tail long and slender, and in the original races fringed. Representations of the greyhound are found on the oldest Egyptian monuments. The permanence and

Persian Greyhound.

peculiarities of the greyhound characters indicate that it arose from an aboriginal independent species, whose primitive seat was probably in the extensive plains of western Asia, extending from Hindostan and Persia through Tartary to Russia, where now the largest

breeds of the race exist, and whence they were carried by or followed man in his migrations into Egypt and Europe. The general colors are black, white, and slaty; the northern breeds have long and shaggy hair, while the southern are smooth or silky, from the effects of climate or from an original difference. The largest and fiercest greyhounds have long hair, like those of the Deccan and Persia, the former of which is of a yellowish tan color, and the latter slaty or white, the hair of both being rather soft; the Arabian greyhound, variously crossed, is large and strong. The Russian and Tartar breeds are large, rough, usually white, black clouded, with long hairy tails; the Scotch greyhound is of the same breed, but, from a probable cross with a staghound, has an excellent nose and considerable sagacity, with great speed and endurance; the Irish greyhound, the largest dog of western Europe, and more than a match for a wolf, is considered of the same breed with the last, crossed in various localities with the great Danish dog, the staghound, and the bloodhound; the Grecian greyhound, still extant, and used in deer

English Greyhound.

hunting, has a rather short and soft fur, slaty and white. Among the smooth-haired breeds are the Turkish, ashy, white, or brindled, with long hairy ears and very pointed nose; the Italian, small, elegant, very delicate, swift, and chiefly regarded as a lady's pet (there is a larger variety resembling this in the Barbary states); and the English greyhound, unrivalled in speed, beauty, and docility, used in the chase of the hare; the last is the most common in western Europe and in the United States. The lurcher (*C. vertagus*) was originally a greyhound, but, from mixture with other breeds and from want of care, has degenerated.

**GREYTOWN.** See SAN JUAN DE NICARAGUA.

**GRIBEAUVAL, Jean Baptiste Vaquette de,** a French artilleryist, born in Amiens, Sept. 15, 1715, died in Paris, May 9, 1789. In 1732 he entered the royal regiment of artillery as a volunteer, in 1752 was sent by the government to study the Prussian system of artillery, and in 1757 was made lieutenant colonel. He now entered the service of Maria Theresa of Austria, and served during the seven years' war with

the rank of general, distinguishing himself especially in the defence of Schweidnitz. Returning to France, he was appointed in 1765 inspector of artillery, and in 1776 inspector general, and devoted the remainder of his life to the improvement of that branch of the service. (See ARTILLERY.) His principal work is *Règlement concernant les fontes et constructions de l'artillerie de France* (3 vols. fol., in 4 parts, with 125 plates, Paris, 1792). Only 125 copies for the use of the government were printed.

**GRIDLEY. I. Jeremy,** an American lawyer, born in Boston, Mass., March 10, 1702, died in Brookline, Sept. 10, 1767. He was educated at Harvard college, and was for a year editor of the "Weekly Rehearsal," a newspaper established in Boston in 1781. He soon acquired great reputation as a lawyer, and was appointed attorney general for the province of Massachusetts Bay. In 1761, while holding this office, he defended the writs of assistance which the Boston custom-house officers had applied for to enable them to enter at discretion the dwellings of suspected individuals. He was eminent for his classical attainments. **II. Richard,** an American soldier, brother of the preceding, born in Boston, Jan. 3, 1711, died in Stoughton, June 20, 1796. In 1745 he served as engineer at the siege of Louisburg, in 1755 was made chief engineer and colonel of infantry, and in the following year took part in the expedition to Crown Point under Winslow, and constructed the fortifications on Lake George. In 1758 he served under Amherst, and subsequently under Wolfe on the plains of Abraham. At the conclusion of the war he received Magdalen island and half pay as the reward of his services. On the outbreak of the revolutionary war he was appointed chief engineer, and constructed the fortifications on Breed's hill the night before the battle of June 17, 1775, in which he was wounded. He was commissioned major general in September, and commander of the continental artillery, but was superseded by Knox in November.

**GRIESEBACH, Johann Jakob,** a German Biblical critic, born at Butzbach, Hesse-Darmstadt, Jan. 4, 1745, died in Jena, March 24, 1812. He was educated at Tübingen, Halle, and Leipsic, and devoted himself to the critical study of the original text of the New Testament. In 1773 he was made extraordinary professor of theology at Halle, and subsequently was elected a professor of divinity at the university of Jena, of which institution he became rector in 1780. The first edition of his Greek Testament was published at Halle in 1775-'7; the second was completed in 1806. Strictly speaking, this was the first critical edition of the New Testament. It was reprinted in London in 1809 and in 1818. An American edition was published in 1808.

**GRIFFIN,** a fabulous monster, half bird, half beast, that dwelt in the Rhipæan mountains, and guarded the gold of the Hyperborean regions from the one-eyed Arimaspians. Griffins were also supposed to watch over the treasures

of India, and the fable probably originated in the East. The fabulists and poets of antiquity represent it with the body of a lion, the head and wings of an eagle, the ears of a horse, and a comb of fishes' fins.

**GRIFFIN, Edward Dorr**, an American divine, born in East Haddam, Conn., Jan. 6, 1770, died in Newark, N. J., Nov. 8, 1837. He graduated at Yale college in 1790, was licensed to preach in October, 1792, and in 1795 was settled as pastor of the Congregational church in New Hartford, Conn., from which in 1801 he was called to the first Presbyterian church in Newark, N. J., where he remained till 1809. In 1808 he was appointed professor of sacred rhetoric in Andover theological seminary, which office he filled till 1811, when he became pastor of Park street church, Boston. There he delivered a series of lectures in exposition of Calvinistic doctrines, afterward published under the title of "Park Street Lectures," and often reprinted. In 1815 he accepted a call to the second Presbyterian church in Newark. In 1821 he became president of Williams college, Mass., and devoted himself most successfully to its interests till 1836, when he resigned and removed again to Newark. Dr. Griffin was a vigorous writer and an eloquent preacher. His publications were numerous, consisting chiefly of sermons and addresses, a selection from which, with a memoir of his life by the Rev. Dr. Sprague, was published in 2 vols. in 1839, and an additional volume of sermons in 1844.

**GRIFFIN, Gerald**, an Irish novelist, born in Limerick, Dec. 12, 1803, died in Cork, June 12, 1840. When he was about 17 years of age his family emigrated to the United States, leaving him at Adare, near Limerick. Determining to devote himself to a literary career, he went in 1823 to London with "Aguire," a tragedy, composed two years previous, which he was unable to dispose of. Another called "Gisippus" (performed after the author's death at Drury Lane with complete success) proving equally unfortunate, he was forced to become a writer for the periodical press, and for several years lived in a precarious manner. He gradually acquired reputation as a brilliant magazine writer, and in 1827 published his "Holland-tide," which was followed shortly by "Tales of the Munster Festivals," both designed to illustrate the manners of the Irish peasantry. In 1828 appeared "The Colleen Bawn, or the Collegians," the most successful of his novels, "The Invasion," "The Rivals," "The Duke of Monmouth," &c. In 1838 he joined the society of the Christian brothers. He was likewise distinguished as a poet. His works have been published in New York in 10 vols., with a memoir by his brother.

**GRIFFIN CITY**, the capital of Spalding co., Georgia, at the junction of the Savannah, Griffin, and North Alabama railroad with the Macon and Western line, 35 m. S. of Atlanta; pop. in 1870, 3,421, of whom 1,588 were colored. It has a healthy situation, is well built,

and carries on an active trade. It has a female college, founded in 1848, a daily, a semi-weekly, and three weekly newspapers, a bank, and several churches.

**GRIFFITH, William**, an English physician, born in 1810, died in Malacca, Feb. 9, 1845. He was educated at the London university, in 1832 went out to India as assistant surgeon, and was appointed by the Bengal government to examine the botany of Tenasserim. In 1835 he was selected to accompany Dr. Wallich to Assam to report on the growth of the tea plant. In 1837 he accompanied Capt. Pemberton on his mission to Bootan, and was subsequently sent to examine the vegetable productions of Afghanistan. In 1841 he was placed on the medical staff at Malacca. He collected animals as well as plants, and his collections of birds alone numbered 600 specimens.

**GRIJALVA, Juan de**, a Spanish navigator, born at Cuellar in the latter part of the 15th century, slain by the Indians in Nicaragua, Jan. 21, 1527. He was intrusted by his uncle, Don Diego Velasquez, the first governor of Cuba, with the command of four vessels, which in the spring of 1518 sailed from Santiago de Cuba, to complete the discoveries which Fernandez de Cordova had made in Yucatan the preceding year. He coasted along the peninsula, and rounding it extended his explorations as far as the region of the Panuco, giving his name and that of his companion, Alvarado, to two rivers on the coast. His communication with the Aztecs was friendly, and so profitable that he was enabled to send back one of the ships freighted with gold, jewels, and other treasures. He afterward settled in Nicaragua, and was slain in the valley of Ulancho.

**GRILLPARZER, Franz**, a German dramatist, born in Vienna, Jan. 15, 1791, died there, Jan. 20, 1872. He was from 1813 to 1856 director of the archives of the ministry of finance, and in 1861 became member for life of the Reichsrath. He was first brought into notice by *Die Ahnfrau*, a tragedy of the fatalistic school, produced in 1816. In 1819 he produced *Sappho*, in 1822 *Das goldene Vlies*, a fantastic work, and in 1825 *König Ottokar's Glück und Ende*. He also wrote comedies and lyrics. A collection of his works in 10 vols. was published in 1872 (2d ed., 1874), and his biography by Kuh in the same year. Early in life he became intimate in the family of Counsellor Fröhlich, after whose death he assumed the guardianship of his three daughters, with whom he resided till his death. At the public celebration of his 80th birthday he was made grand cross of the order of Francis Joseph.—See *Grillparzer als Archiv-Director*, by G. Wolf (Vienna, 1874).

**GRIMALDI**, one of the four great patrician families of Genoa. They derive their descent from Grimoald, mayor of the palace under the Frankish king Childebert II., and first made their appearance in northern Italy in the 10th century. In 980 they gained possession of the lordship of Monaco, of which they

remained the hereditary princes for upward of seven centuries. They belonged to the Guelph faction, and coöperated with the Fieschi in those incessant struggles with the Ghibellines, headed by the Doria and Spinola families, which kept Genoa in a turmoil; and notwithstanding the law of 1339 excluding the nobles, both Guelph and Ghibelline, from holding supreme authority in the state, they continued to exert the greatest influence in the government of their country. The Grimaldis possessed large estates in France and Italy. Branches of this family still exist in Nice and southern France. RANIERI II. was the first Genoese who led the fleet of the republic beyond the strait of Gibraltar. As an ally of Philip the Fair of France, he defeated in 1304 the Flemish fleet under Guy of Flanders, whom he took prisoner. CARLO II., sur-named the Great, commanded the Genoese crossbowmen in the battle of Crécy. His troops, rendered helpless by the damage which a heavy shower had caused to their bow-strings, were attacked not only by the English, but also by the French, who were enraged at the falling back of their allies, and a dreadful carnage ensued, in which their commander was killed (1346). ANTONIO, an admiral, in 1332 avenged the aggressions of the Catalonians and Aragonese by ravaging their coasts. The supremacy which the Genoese thus gained was maintained till 1353, when the combined Catalonian and Venetian fleets, under command of Nicolò Pisani, inflicted a disastrous defeat upon Grimaldi off the coast of Sardinia, by which the naval strength of Genoa was for a time prostrated. GIOVANNI, in the service of the Milanese, gained a decided victory over the Venetian fleet under Trevesani on the Po, in 1431, taking numbers of galleys and immense spoils. DOMENICO distinguished himself as a zealous churchman, and also as a naval commander at the battle of Lepanto (1571). He was advanced to the dignity of cardinal, and extirpated heretical doctrines from his diocese. GERONIMO, who died in 1685 at the age of 89, was also an ecclesiastic, and as bishop of Aix effected some very wholesome reforms in his diocese. He annually distributed 100,000 livres in alms. He was sent as nuncio to Germany by Urban VIII., who made him a cardinal.

**GRIMES**, an E. county of Texas, bounded W. by Navasoto and Brazos rivers; area, 902 sq. m.; pop. in 1870, 13,218, of whom 7,921 were colored. The surface is rolling and occupied by prairies and forests. Much of the soil is a rich black loam. The county is traversed by the Houston and Texas Central railroad. The chief productions in 1870 were 336,690 bushels of Indian corn, 80,966 of sweet potatoes, and 10,025 bales of cotton. There were 3,569 horses, 1,305 mules and asses, 5,779 milch cows, 4,765 working oxen, 17,814 other cattle, 3,794 sheep, and 15,913 swine; 3 saw mills, and 3 carriage factories. Capital, Anderson.

**GRIMES, James Wilson**, an American statesman, born in Deering, N. H., Oct. 20, 1816, died in Burlington, Iowa, Feb. 7, 1872. He graduated at Dartmouth college in 1836, and removed to Burlington, where he began the practice of law. He was a delegate to the first territorial legislature of Iowa in 1838, and held a seat in the state legislature for several terms. In 1854 he was the whig and freesoil candidate for governor, canvassed the state in person, and was elected, though his party had previously been in the minority. He held the office three years, and did much to secure liberal legislation in behalf of common schools and a better treatment of the insane. He was elected to the United States senate in 1859, and reelected in 1865. In the senate he was chairman of the committees on naval affairs and public lands, and a member of the special joint committee on the rebellious states. On the trial of President Johnson he was one of the few republican senators who voted for acquittal. In 1869, in consequence of a stroke of paralysis, he resigned his seat in the senate, and made a brief tour in Europe.

**GRIMKÉ. I. Thomas Smith**, an American lawyer and scholar, born in Charleston, S. C., Sept. 26, 1786, died near Columbus, O., Oct. 12, 1834. He graduated at Yale college in 1807, studied law in Charleston, and rose to eminence at the bar and in politics. Among his more noted efforts were a speech in the state senate on the tariff question in 1828, in which he supported the general government, and an argument on the constitutionality of the South Carolina test act in 1834. He became more widely known by his addresses in behalf of peace, religion, and literature. An early and prominent advocate of the American peace society, he held the opinion that even defensive warfare is wicked. He entertained some eccentric notions on the subject of education, and in several pamphlets he introduced a new system of English orthography. He published several addresses before Sunday schools and peace societies, before the society of the Cincinnati at Charleston, July 4, 1809, and before various societies and associations on subjects connected with education. A volume of his addresses was published at New Haven in 1831. **II. Frederick**, brother of the preceding, born in Charleston, S. C., Sept. 1, 1791, died March 8, 1863. He removed to Ohio, where he held for many years the office of judge of the court of common pleas and of the supreme court. He was the author of a work on "The Nature and Tendency of Free Institutions" (Cincinnati, 1848), and of an essay on "Ancient and Modern Literature." **III. Sarah Moore**, sister of the preceding, born in Charleston, S. C., Nov. 26, 1792, died at Hyde Park, Mass., Dec. 23, 1873. From early youth she and her younger sister Angelina felt a strong repugnance to slavery, and on receiving slaves by inheritance immediately set them free. About 1828 they removed to Philadelphia and joined

the society of Friends. In 1836 they began to lecture against slavery, and their addresses had great influence on public opinion. In 1837-'8 Sarah visited Massachusetts, making many public speeches, and wrote for Garrison's "Liberator" a series of letters on "The Equality of the Sexes," which were afterward published in a volume. In these letters all the principles and nearly all the arguments since advanced by the woman's rights party were anticipated. In the latter part of her life Miss Grimké was a teacher of French, and translated and published Lamartine's *Jeanne d'Arc* and Émile Souvestre's *Confessions d'un ouvrier*. Her sister became the wife of Theodore Dwight Weld. (See WELD.)

**GRIMM, Friedrich Melchior**, baron, a French critic, born in Ratisbon, Dec. 26, 1723, died in Gotha, Dec. 19, 1807. After distinguishing himself as a scholar at Leipsic, he accompanied Count Schönberg to Paris as tutor to his children. He soon afterward became reader to the prince of Saxe-Gotha, gained the acquaintance of J. J. Rousseau about 1749 by his taste for music, was introduced into the circle of the encyclopædists, and was made secretary successively of Count Friesen and of the duke of Orleans. He was noted for romantic and sentimental amours, and joined the coterie of critics who favored the Italian and assailed the French opera. He achieved his first literary success by a pamphlet entitled *Le petit prophète de Bohémischbroda* (Paris, 1753), a plea in Biblical style for Italian music, which, together with several lively and enthusiastic critiques on the arts, gave him the reputation of one of the most brilliant French writers. Employed by the abbé Raynal to conduct his foreign correspondence, Grimm became the regular correspondent of seven royal personages, among whom were Catharine II. of Russia, Gustavus III. of Sweden, and Stanislas Poniatowski of Poland, chronicling for them the literary movements for which Paris was then distinguished. This correspondence, which gives a detailed history of French literature from 1753 to 1790, is one of the best collections of criticism of the 18th century. No important work appeared in France during that period which is not the subject of ingenious and piquant remarks. He was appointed in 1776 by the duke of Saxe-Gotha his envoy at the French court, and saw the outbreak of the French revolution and described its early scenes, but retired from Paris with the other members of the diplomatic corps, and passed his last years at Gotha, holding from 1795 the title of minister plenipotentiary of Russia. His *Correspondance littéraire, philosophique et critique* was published in Paris (16 vols., 1812-'13). A new edition, annotated by Taschereau (5 vols., 1829-'31), contains passages suppressed by the censorship under the Napoleonic régime. The *Correspondance inédite de Grimm et Diderot* appeared in 1829, and *Études sur Grimm*, by Sainte-Beuve and Paulin Limayrac, in 1854.

**GRIMM. I. Jakob Ludwig**, a German philologist, born in Hanau, Jan. 4, 1785, died in Berlin, Sept. 20, 1863. He studied law in the university of Marburg under Savigny, whom in 1805 he accompanied to Paris. In 1806 he returned to Hesse, was appointed secretary of war, and devoted his leisure to the literature of the middle ages. He participated in the congress of Vienna (1814-'15), and was sent to Paris by the Prussian government to obtain manuscripts carried thither by Napoleon. He was second librarian at Cassel from 1816 to 1830, when he became professor and librarian at Göttingen, and for seven years lectured on the antiquities of the German language, literature, and law. In 1837 he was one of the seven professors who signed the protest against the abolition of the constitution by the king of Hanover, for which he with most of the signers was deprived of his office and banished. He published a pamphlet on the subject entitled *Jakob Grimm über seine Entlassung* (Basel, 1838). In 1841 he was called to Berlin as member of the academy of sciences and as professor. He presided over the assemblies of German philologists held in Frankfurt in 1846 and in Lübeck in 1847, was a member of the Frankfurt parliament of 1848, and participated in the gathering at Gotha in 1849, acting with the moderate liberal party. His first publication was *Ueber den altdeutschen Meistergesang* (Göttingen, 1811). It was followed by his *Deutsche Grammatik* (4 vols., 1819-'37), containing a history of the grammatical forms of all the Germanic dialects in the different eras of the language. His *Deutsche Rechtsalterthümer* (1828; new ed., 1854) recounts the poetical and fantastic customs which flourished among the Germans in the middle ages; and his *Deutsche Mythologie* (1835; 2d ed., 1843) is a complete discussion of the old gods of the North. His *Geschichte der deutschen Sprache* (2 vols., Leipsic, 1848; 2d ed., 1853) traces the ethnological affinities of the Germanic nations by comparative philology. Among his numerous other works are a collection of German proverbs, *Weisthümer* (4 vols., Göttingen, 1840-'63), and editions of various mediæval productions. He also published, in connection with his brother Wilhelm Karl, the German *Kinder- und Hausmärchen* (Berlin, 1812; often republished, and translated into English and French), one of the most popular collections of juvenile stories; *Altdeutsche Wälder* (3 vols., Cassel, 1813-'16); *Die Lieder der Alten Edda* (Berlin, 1815); *Deutsche Sagen* (2 vols., Berlin, 1816-'18); and *Irische Elfenmärchen* (Leipsic, 1826), founded on Croker's "Fairy Legends." In 1852 he and his brother commenced the publication of the *Deutsches Wörterbuch*, on a plan more elaborate and extensive than that of any dictionary of any modern language. It was intended to include every word employed in German literature from Luther to Goethe. He lived to complete three volumes and a part of the fourth, embrac-

cing but a small part of the alphabet. The completion of the work, his brother having died before him, was intrusted to Moritz Heyne, Rudolf Hildebrand, and Karl Weigand; and it is said that the brothers Grimm left sufficient materials to carry out the original plan in all its essential features. The first part of vol. iv., reaching to the word *Garten*, was published in Leipsic at the beginning of 1874. The work was completed nearly to the letter L, and it is expected that the whole will be ready about 1890. Since his death three volumes of his minor writings (*Kleinere Schriften*), including an autobiography, have been published. **II. Wilhelm Karl**, a German philologist, brother of the preceding, born in Hanau, Feb. 24, 1786, died in Berlin, Dec. 16, 1859. He was educated at Cassel and Marburg, was appointed in 1814 secretary of the library of Cassel, and in 1830 assistant librarian at Göttingen, where he became professor in 1835. He was deprived of this office in 1837, and accompanied his brother to Cassel and Berlin. He devoted himself especially to German mediæval poetry, and, besides the works which were the joint productions of the two brothers, wrote treatises *Ueber die deutschen Runen* (Göttingen, 1821) and *Ueber die deutschen Fingernamen* (Berlin, 1848); translated the *Alt-dänische Heldensieder, Balladen und Märchen* (Heidelberg, 1811); and edited the *Grave Ruodolf* (Göttingen, 1828), *Die deutsche Heldensage* (1829), *Der Freidank* (1834), *Der grosse Rosengarten* (1834), *Das Rolandslied* (1838), *Wernhers vom Niederrhein Veronica* (1839), *Konrads von Würzburg Goldene Schmiede* (Berlin, 1840), *Athis und Prophilias* (1846), *Echortatio ad Plebem Christianam* (1848), and *Altdeutsche Gespräche* (1851), for all of which he furnished introductions and disquisitions of great value. **III. Ludwig Emil**, a German painter and engraver, brother of the preceding, born in Hanau in 1790, died in Cassel, April 4, 1863. He studied under Karl Hess at Munich, served in the campaign of 1813, and in 1817 went to Italy. In 1832 he became professor in the academy of painting at Cassel. He made more than 130 engravings, most of them his own compositions. Of his paintings, a "Madonna" and numerous portraits are most admired. **IV. Hermann Friedrich**, son of Wilhelm Karl, born in Cassel, Jan. 6, 1828. He studied at Berlin and Bonn, and has since 1849 resided in the former city. Among his works are the drama *Arminius* (1851), the tragedy *Demetrius* (1854), the poem *Traum und Erwachen* (1854), *Novellen* (1856; 2d ed., 1862), *Essays* (1859), *Leben Michel Angelo's* (2 vols., 1860-'63; 3d ed., 1868; English translation by F. E. Bunnett, 2 vols., 1865), *Neue Essays* (1865), mainly devoted to the writings of Emerson, and the novel *Unüberwindliche Mächte* (3 vols., 1867). He has also edited *Ueber Künstler und Kunstwerke* (3 vols., 1865-'7).

**GRIMMA**, a town of Saxony, on the Mulde, 14 m. S. E. of Leipsic; pop. in 1871, 6,536. It is pleasantly situated, and contains several church-

es, an ancient town hall, and a royal palace which is used for public offices. Celebrated among its schools is the *Fürstenschule (Illustre Moldanum)*, with more than 120 pupils and a library of 6,000 volumes. Grimma was the most important commercial and manufacturing emporium of Saxony until the 14th century, but has considerably declined. The local industry has lately somewhat revived, and it also contains two large publishing houses. The *Goltermühle*, outside the town, includes an extensive manufactory of paper and machinery, and an iron foundery. Albert the Brave, progenitor of the Saxon dynasty, was born in the castle of Grimma in 1443.

**GRINDAL**, Edmund, an English prelate, born at Kensington, Cumberland, in 1519, died at Croydon, July 6, 1583. In 1459 he became president of Pembroke hall, Cambridge, and, having greatly distinguished himself as a preacher, became Bishop Ridley's private chaplain in 1550. The next year he was appointed chaplain to the king; but on the accession of Mary he fled to Strasburg, where he remained till her death, when returning, he was employed to draw up the new liturgy, and, with seven other Protestants, to oppose the Roman Catholic prelates in public debate. In 1559 he was made master of Pembroke hall, and the same year was nominated to succeed Bonner as bishop of London. In 1570 he was translated to the see of York, and five years after succeeded Parker as archbishop of Canterbury. Elizabeth, disliking the frequent meetings of the clergy for mutual improvement, directed Grindal to break up these "propheysings." Venturing decidedly to question the propriety of doing this, he was confined to his house by order of the star chamber, and his see was sequestered. He was afterward partially restored, but in 1582 he became blind, and resigned, receiving a pension. He wrote little, but a tract of his on the real presence is printed in Fox's "Acts and Monuments."

**GRINDELIA**. See supplement.

**GRINDELWALD**, a village of Switzerland, in the canton and 36 m. S. E. of the city of Bern, and 10 m. E. S. E. of Interlaken, about 3,500 ft. above the sea, on the Bergelbach; pop. about 3,000. It is the centre of the road to the Bernese Oberland, and is celebrated for the scenery of the Grindelwald valley, the beauty of the passes of the Scheideck, and the surrounding mountains and glaciers. The village consists of picturesque wooden cottages widely scattered over the valley. The inhabitants are mainly employed in rearing cattle, in dairy work, and in preparing *Kirschwasser*. The most celebrated Swiss guides are natives of this vicinity. Owing to the proximity of the glaciers, the climate is cold and unsettled even in summer.—The Grindelwald valley is traversed by the Black Lütchine, and is about 16 m. long and 2 m. wide. South of the valley rise the Wellhorn, Wetterhorn, Mettenberg, Schreckhorn, Eiger, and Mönch; and north

the Faulhorn and other mountains. About 4 m. S. E. of the village the two glaciers of Grindelwald issue from both sides of the Mettenberg; they belong to the field of ice which occupies the table land and elevated valleys of the Bernese Alps. The upper one descends lower than any other glacier in Switzerland, being almost on a level with inhabited houses. It is accessible without danger, and the little or lower glacier is so easily explored that it is popularly known as the *Damengletscher* (lady's glacier).

**GRINNELL**, a town of Poweshiek co., Iowa, at the intersection of the Central railroad of Iowa with the Chicago, Rock Island, and Pacific line, about 50 m. E. by N. of Des Moines; pop. in 1870, 1,482. It is in a fertile undulating prairie, and is the seat of Iowa college (Congregational), originally established at Davenport. This institution was organized in 1848, and has a normal and English department, besides academic courses and a regular collegiate course. It possesses a valuable museum of natural history and extensive philosophical apparatus. The college and society libraries contain 6,500 volumes. In 1872-'3 there were 19 professors and 338 students.

**GRINNELL LAND**, a tract of land in the Arctic ocean, separated from Greenland by Kennedy channel and Robeson strait. Its discovery has been claimed by both English and American explorers. It was seen by the first American Grinnell expedition in search of Sir John Franklin, under Lieut. De Haven, Sept. 22, 1850, and eight months later was visited by Capt. Penny in the British vessel *Lady Franklin*. This officer, ignorant of its previous discovery, gave it the name of Prince Albert land. Dr. Kane, on his second expedition in 1854, explored and mapped it toward the west and north, in lon. 76° W., and as far N. as lat. 82°. Capt. Hall in 1871 sailed up its coast to lat. 82° 16', and his crew reported that its extreme N. point appeared to be about lat. 83° 20', whence the shore trended westward.

**GRIQUAS**, or **Baastaards**, a mixed race of S. Africa, consisting of the progeny of Dutch settlers by Hottentot and Bush women. They occupy the right bank of the great bend of Gariep or Orange river, on the N. frontier of Cape Colony, and are supposed to number about 15,000 souls, most of whom profess Christianity and are partly civilized. They have a prosperous community at Griqua Town, about 500 m. N. E. of Cape Town, under the direction of the London missionary society. This place was the seat of a well known Christian chief named Waterboer, who managed during his reign of 30 years (about 1814-'44) to break up the marauding practices for which his people had been noted. The chiefs are elected. The people retain many of the characteristics of both African and European progenitors. The Christians of this race are generally well clad. Many of them are thriving agriculturists and cattle breeders.

**GRISAR, Albert**, a French composer, born in Antwerp, Dec. 26, 1808, died at Asnières, near Paris, June 14, 1869. He was sent to Liverpool to qualify himself for business pursuits, but left that city secretly and studied music in Paris under Reicha. The outbreak of the Belgian revolution soon obliged him to return to Antwerp, where he continued to practise his art, and his first productions, the ballad *La folle* and the comic opera *Mariage impossible*, made him famous and won from the Belgian government an allowance of 1,200 francs. He then took up his permanent residence in Paris. The best of his earlier comic operas, each in one act, are *L'Eau merveilleuse* (1844), *Gilles ravisseur* (1849), and *Bon soir, Monsieur Pantalón*. Among his later works, in three acts, are *Les amours du diable* (1853), *La chatte merveilleuse* (1862), and *Les bégayements de l'amour* (1864); but one of the most popular is the one-act piece *Le chien du jardinier*, first performed in 1855. He had *Afraja*, in three acts, *Rigolo*, in one act, and four other new operas nearly completed at the time of his death. His most popular ballad is *Adieu, beau rivage de France*.

**GRISCOM. I. John**, an American educator, born at Hancock's Bridge, Salem co., N. J., Sept. 27, 1774, died in Burlington, N. J., Feb. 26, 1852. He belonged to a family of Friends, passed his youth on a farm, and began to teach when but 17 years old. He studied for a time at the Friends' academy in Philadelphia, and afterward for 13 years had charge of the Friends' monthly meeting school in Burlington, during which time students were attracted thither from all the surrounding states. In 1807 he removed to New York, and taught there for 25 years. In 1818-'19 he travelled extensively in Europe, visiting the principal institutions of learning and charity, prisons, and manufactories, and in 1823 published "A Year in Europe" (2 vols.). He was one of the founders and for six years secretary of the society for the prevention of pauperism, and was the author of many of its reports. He was also the projector of the New York high school, which was under his supervision from 1825 to 1831. He was literary principal of a Friends' boarding school in Providence, R. I., from 1831 to 1835, when he removed to Burlington. In the last years of his life he reorganized the common school system of New Jersey. His biography, by his son John H. Griscom, was published in New York in 1859. **II. John Hoskins**, an American physician, son of the preceding, born in New York, Aug. 13, 1809, died there, April 28, 1874. He studied at the Rutgers medical college, New York, and at the university of Pennsylvania, where he graduated in 1832, his inaugural thesis being published by the faculty. In 1833 he was appointed assistant physician to the New York dispensary, and in 1834 chief physician. He was professor of chemistry in the New York college of pharmacy from 1836 to 1840. In 1843 he was appointed

ed physician to the New York hospital, which post he held till 1867. He was for 15 years a member of the prison association, and for 10 years the chairman of its executive committee. He paid much attention to hygiene and the ventilation of buildings, and wrote several treatises upon these subjects. His principal works are: "Animal Mechanism and Physiology" (1839); "Sanitary Condition of the Laboring Classes of New York" (1844); "Uses and Abuses of Air, and the Means for the Ventilation of Buildings" (1850); "Hospital Hygiene" (1853); "A History, Chronological and Circumstantial, of the Visitations of the Yellow Fever in New York" (1858); "First Lessons in Physiology, with Brief Rules of Health, for the use of Schools" (1860); "Sanitary Legislation, Past, Present, and Future" (1861); and "Use of Tobacco, and the Evils resulting from it" (1868).

**GRISEBACH, August Heinrich Rudolf**, a German botanist, born in Hanover, April 17, 1814. He studied in Göttingen and Berlin, and became in 1837 adjunct and in 1847 regular professor of botany in the university of Göttingen. He published *Reise durch Rumelien und nach Brussa im Jahre 1839* (2 vols., Göttingen, 1841); and among his many botanical works is *Die Vegetation der Erde nach ihrer klimatischen Anordnung: ein Abriss der vergleichenden Geographie der Pflanzen* (2 vols., with a map, Leipsic, 1872). The author in this work gives a geographical description of plants in relation to the physical history of the earth.

**GRISI, Giulia**, an Italian singer, born in Milan in 1812, died in Berlin, Nov. 25, 1869. She was the daughter of Gaetano Grisi, who was an officer of engineers, and niece of the singer Grassini; and she was assisted in her musical studies by her elder sister Giuditta, who was also a celebrated singer. On her début in Bologna at the age of 17 she made a great impression by the grace and loveliness of her person, her intelligence, and fine vocal abilities. In 1832 she took the part of Adalgisa on the first representation of Bellini's *Norma* at Milan, and shared with Pasta, who personated Norma, the triumph of the occasion. She had previously entered into a contract with Lanari, the *impresario* at Florence, to sing for him for six years at a very moderate salary; but finding that her talents could command higher pay elsewhere, she secretly fled to France to avoid her obligations. In Paris, through the influence of Rossini, she was engaged as prima donna of the Italian opera; and in 1834 her début in London was very successful. In the parts of Norma, Semiramide, Lucrezia Borgia, and Elvira in *I Puritani*, she showed dramatic capacities which rendered her scarcely less attractive as an actress than as a singer; while in the buffo music of *Il barbiere di Siviglia*, *Don Pasquale*, or *Cenerentola*, she was almost equally successful. In August, 1854, in company with Signor Mario, she visited the United States. In 1836 she married in London M. de

Meley, but retained in her profession her former name. The marriage was unhappy and was judicially dissolved. Mme. Grisi subsequently married Mario.

**GRISONS** (Ger. *Graubünden*), the easternmost and largest of the Swiss cantons, bordering on Liechtenstein, Tyrol, Italy, and the cantons of St. Gall, Glarus, Ticino, and Uri; greatest length 90 m., greatest breadth 64 m.; area, 2,774 sq. m.; pop. in 1870, 91,782, of whom about 52,000 were Protestants. The whole canton is an alternation of valleys and mountains, several of the latter of which reach an elevation of from 10,000 to 13,000 ft. above the sea. Among the Alpine mountain passes are those of the Bernardino, Splügen, Julier, and Bernina; among the valleys is the Engadine. The scenery is surpassingly grand. The climate is more diversified than is usual even in Switzerland. While on the mountains winter reigns for more than half the year, the air of the vale below is almost as mild and genial as that of Italy. In the loftier districts the snow sometimes continues as late as July, but in the valleys which look toward the south cultivation can commence as early as the beginning of March. The principal rivers are the upper courses of the Rhine and Inn, and several tributaries of the upper Ticino and Adda. The chief productions are rye, barley, oats, timber, hemp, flax, potatoes, fruit, wine, cheese, and cattle; the rearing of the last constitutes the great business of the inhabitants. Iron, lead, and zinc are produced, but not extensively mined. There are no manufactures of importance, but a considerable transit trade is carried on through the canton between Italy and Germany. The annual value of exports is about 6,500,000 francs; of imports, 8,000,000. The canton is divided into three leagues, the *Graubund* (league of counts, or gray league), *Gotteshausbund* (league of God's house), and *Zehngerichtenbund* (league of ten jurisdictions), which are governed by their respective presidents and by a general diet of deputies from each *Bund*. They are subdivided into communes, each of which was formerly almost independent within its own limits. Of late centralization has made some progress; the cantonal government has received greater powers, and cantonal courts have taken the place of the former independent courts. As a canton the country is now divided into 14 districts, which are subdivided into circles. The name of the canton is said to be derived from the color of the dress worn by a band of the people who in 1424 met in a forest near Trons and bound themselves to defend each other against their feudal lords. Formerly Romansh was the language of the entire population; the first German settlers came into the country about 600 years ago, since which time the German language has steadily gained ground, until by the census of 1870 the number of German families was found to exceed the Romansh. Capital, Coire.

**GRISSEH**, or *Grissee*, a town of Java, 12 m. N. W. of the city of Surabaya, on the strait of Madura; pop. not stated, though believed to be numerous, and mainly consisting of Javanese and Chinese. The principal houses extend along the shore and are shaded by tamarind trees, and many of the residents are scattered over a large distance inland, but in a much less healthy locality. The finest buildings are a Chinese temple and the dwelling of the Dutch resident. The roadstead is the safest on that part of the Javanese coast, and ship building is actively carried on. Salt and saltpetre abound in the vicinity. It is one of the most ancient towns of Java; and here Mohammedanism was first firmly established.

**GRISWOLD, Alexander Viets**, a bishop of the Protestant Episcopal church in the United States, born in Simsbury, Conn., April 22, 1766, died in Boston, Mass., Feb. 15, 1843. His early education was mainly derived from his uncle, the Rev. Roger Viets, rector of the Episcopal church in Simsbury. Mr. Viets during the revolution sided with the royalists, and removed to Nova Scotia in 1787; but he was unable to persuade his nephew to go with him. After some hesitation between law and divinity, Mr. Griswold was ordained June 3, 1795. He entered at once upon a large field of labor, including East Plymouth, Harwinton, and Northfield, at the same time teaching a district school. In 1804 he accepted a call to Bristol, R. I., where he labored with much success. On the formation in 1810 of what was called the Eastern diocese, composed of New Hampshire, Vermont, Massachusetts, and Rhode Island, Dr. Griswold was elected bishop. At first he declined, not deeming himself qualified for the office; but his scruples having been removed, he was consecrated by Bishop White, May 29, 1811. He continued to hold the rectorship of the church in Bristol till 1830, when he removed to Salem, Mass. On Bishop White's death in 1836, he became presiding bishop. In June, 1838, the Rev. Dr. Alonzo Potter was elected his assistant, but declined. Dr. Eastburn of New York was elected in 1842, and his consecration, Dec. 29, was Bishop Griswold's last public act. He was highly esteemed for his meekness, soundness of judgment, and gentle, courteous demeanor. His publications were mostly sermons addressed to conventions of the church, and a volume of "Sermons on the most important Doctrines and Duties of the Christian Religion" (8vo, 1830).—A "Life" of Bishop Griswold was written by the Rev. J. S. Stone, D. D.

**GRISWOLD, Rufus Wilmot**, an American author, born in Benson, Rutland co., Vt., Feb. 15, 1815, died in New York, Aug. 27, 1857. A great part of his early life was spent in roaming about the world. He had learned the printing trade, which he followed for some time, and afterward studied divinity and became a Baptist preacher. He soon became associated in the editorship of literary periodicals in Boston,

New York, and Philadelphia, among which were the "New Yorker," "Brother Jonathan," and "New World." In 1841 he published a volume of poems and one of sermons, the former anonymously. In 1842 and 1843 he edited "Graham's Magazine" in Philadelphia, and in 1850 he projected the "International Magazine," published in New York, and edited by him till April, 1852. The works by which he is chiefly known are collections of specimens from American authors, accompanied by memoirs and critical remarks. The first of these was the "Poets and Poetry of America" (Philadelphia, 1842; 17th ed., 1856). It was followed by the "Prose Writers of America" (Philadelphia, 1846; 4th ed., 1856), and by the "Female Poets of America" (Philadelphia, 1849; 5th ed., 1857; new ed. by R. H. Stoddard, 1874). Mr. Griswold also edited the "Sacred Poets of England and America" (1849), and the "Poets and Poetry of England in the Nineteenth Century" (4th ed., 1854). His other principal publications are "Curiosities of American Literature," published as an appendix to Disraeli's "Curiosities of Literature;" two series of biographies, "Washington and the Generals of the American Revolution," in conjunction with W. G. Simms, E. D. Ingraham, and others (2 vols., 1847), and "Napoleon and the Marshals of the Empire," in conjunction with H. B. Wallace (2 vols., 1847); and "The Republican Court, or American Society in the Days of Washington" (New York, 1854).

**GRITTI. I. Andrea**, doge of Venice, born in 1454, died Dec. 28, 1538. During the war against the league of Cambrai he led the armies of the republic against the imperialists, whom he at first defeated and drove out of Padua and Vicenza. In 1512 he regained Brescia and Bergamo from the French, but was shortly after defeated and made prisoner by Gaston de Foix, who took him to Paris. During his imprisonment he formed an alliance between France and the Venetian republic, and on his return to Venice he coöperated with French troops in driving the imperialists out of Brescia and overrunning the kingdom of Naples. In May, 1523, he was elected doge, and filled that office until his death. **II. Luigi**, an adventurer in the service of the Turks, son of the preceding by a Turkish slave, born in Constantinople in 1501, while his father was ambassador there, died in Transylvania, Sept. 28, 1534. He was educated at Padua, but finding no honorable employment open to him in Italy, he went to Constantinople, ingratiated himself with the grand vizier, and became a favorite with Solymán II., who intrusted him with diplomatic missions to various nations. He persuaded his master to support the claims of John Zápolya to the throne of Hungary, and took part in the attack on Vienna in 1529. After the coronation of Zápolya at Buda, Gritti was appointed governor general of Hungary, but abused his power by a bloody persecution of his enemies. The murder of the vicar of the

bishopric of Grosswardein and governor of Transylvania finally aroused the indignation of the people of that province, who marched against him with an overpowering force, besieged him in Mediasch, and put him to death.

**GROAT** (Dan. *groot*, Ger. *gross*, great), an old English silver coin, of the value of four pence (originally about equal to the present shilling), first struck under Edward III. about 1351, and so named because it was the greatest silver coin then in use, none having been previously struck of value over a penny. The *grot*, *groot*, and *groschen* are silver coins or moneys of account on the continent of Europe.

**GRODNO. I.** A government of European Russia, in Lithuania, formerly a part of Poland, bordering on Wilna, Minsk, Volhynia, and the kingdom of Poland; area, 14,960 sq. m.; pop. in 1867, 958,852, the large majority of whom are Roman Catholics. The surface is generally level, and a great portion of it is covered with pine forests and swamps. The principal productions are rye, barley, timber, hops, hemp, flax, fruit, honey, and cattle. The most important minerals are iron, chalk, limestone, and nitre. The forests abound with wild boars, wolves, bears, elk, and roebucks. The manufactures consist for the most part of woollen stuffs, hats, and leather. The chief rivers are the Niemen, Bug, Narew, and Pripetz. The principal towns are Grodno, Novogrodek, and Slonim. **II.** A city, capital of the government, on the right bank of the Niemen, 93 m. S. W. of Wilna; pop. in 1867, 24,789, among whom are many Jews. It has several Roman Catholic and Greek churches, a Lutheran church, two synagogues, an academy of medicine, a gymnasium, a military school for young noblemen, several other educational institutions, and manufactories of cloth, silk, and cotton. After 1673 every third Polish diet was held here, and in 1793 the Polish diet was here forced to assent to the second division of Poland.

**GRONINGEN. I.** A N. E. province of the Netherlands, bordering on the North sea and the estuary of the Ems, Prussia, and the provinces of Drenthe and Friesland; area, 885 sq. m.; pop. in 1870, 234,903. The surface is generally level, and in some places marshy. The climate is humid and unhealthy. The soil is very fertile, and is watered by numerous rivers and canals. The productions are corn, potatoes, butter, cheese, coal, flax seed, honey, wool, seeds, fruits, pigs, and cattle, which form the great exports from the province. It is divided into the districts of Groningen, Winschoten, and Appingadam. **II.** A city, capital of the province, at the junction of the Aa and the Hunse, 92 m. N. E. of Amsterdam; pop. in 1870, 38,258. The streets are traversed by canals, bordered with trees and crossed by 18 bridges. The principal public edifice is the province house, a large Gothic structure completed in 1810. It has a university which was established in 1614, academies of design, of

architecture, and of navigation, several learned associations, manufactories of paper, brushes, linen, and woollens, and a considerable trade in corn, butter, cheese, cattle, and wool. About 600 vessels arrive at and leave the port annually. Canals connect the town with the Dollart and the Zuyder Zee.—Groningen appears as a village in the 9th century, when the surrounding territory belonged to Friesland. In the 10th century it was annexed to the German empire, and was subsequently governed by imperial burgraves. Having become a free city, it joined the Hanse league. Maximilian I. bestowed the hereditary governorship of the city and country on the dukes of Saxony. The people revolted, and after a struggle placed themselves under the protection of the duke of Gelderland, who subsequently became a vassal of Charles V. The province joined the league of Utrecht in 1579. The capital was repeatedly besieged during the Dutch war of independence, Maurice of Nassau capturing it in 1594.

**GRONOVIVS**, the Latinized form of Gronov, the name of a German family settled in Holland. **I. John Frederick**, born in Hamburg, Sept. 8, 1611, died in Leyden, Dec. 28, 1671. He was educated at Leipsic and Jena, and studied law at Altorf. In 1634 he became a private tutor in Amsterdam, but three years later he gave up all other pursuits for the study of antiquities and the classics. He spent much time in England, France, and Italy, studying old manuscripts and rare books. In 1643 he was appointed rector of the gymnasium of Deventer, and in 1658 professor of belles-lettres at Leyden. He published annotated editions of Livy, Tacitus, Seneca, Sallust, Pliny, and other classical writers, and numerous essays on philology and antiquities. **II. Jacobus**, his eldest son, born in Deventer, Oct. 20, 1645, died in Leyden, Oct. 21, 1716. In 1668 he visited Oxford and Cambridge to study antiquities, and in 1672 went to Madrid as a member of the embassy from the states general. He was for two years professor of belles-lettres in the university of Pisa, and from 1679 in Leyden. He published editions of many of the classical writers, but is best known by his *Thesaurus Antiquitatum Græcarum* (13 vols. fol., Leyden, 1697–1702). **III. Abraham**, son of the preceding, born in Leyden in 1694, died there, Aug. 17, 1775. He practised medicine successfully in England and in Holland, but finally became librarian to the university of Leyden. He published editions of Justin, Pomponius Mela, and Tacitus, and several works exhibiting much classical erudition. **IV. John Frederick**, brother of the preceding, born in Leyden, March 10, 1690, died there in 1760. He studied jurisprudence and was a magistrate of Leyden, but devoted himself to botany, and was intimate with Linnæus. Among his works are *Flora Virginica* (1743), and *Flora Orientalis* (1755). **V. Laurentius Theodorus**, a naturalist, son of the preceding, born in Leyden in 1730,

died there in 1778. He published *Bibliotheca Regni Animalis* (4to, 1740), *Museum Ichthyologicum* (2 vols. fol., 1754-'6), and *Zoophylacium Gronovianum* (fol., 1763-'81).

**GROOT, Gerhard**, or **Gerard the Great**, founder of the congregation of "Brethren and Clerks of the Common Life," born in Deventer, Holland, in 1340, died Aug. 20, 1384. He studied in Paris, graduated master of arts at the age of 18, and taught philosophy and theology at Cologne, where his eloquence and learning gained him the surname of Magnus. Although not in priestly orders, he held several rich benefices, besides a considerable patrimony, and lived in great luxury until an interview with the prior of a Carthusian monastery at Geldern induced him to enter the religious state. He renounced his benefices, and after three years was ordained deacon, refusing higher advancement. He now passed through the principal cities of the diocese of Utrecht, preaching with extraordinary effect to immense audiences, and working reforms no less among the clergy than among the laity. He assailed scholastic theology, taught that the reading of the Scriptures and of the writings of the fathers should be one of the chief occupations of a Christian, and translated the Psalms and the church office into Dutch. Having collected some of the best manuscript copies of the Bible and the fathers, he established in his own house at Deventer a society whose principal employment was the transcribing of these books. He gave them a rule of life, prescribed community of goods, and placed over them Florent Radewyn, professor in the university of Prague, a rich man who had been converted by Gerhard's preaching. The "Brethren and Clerks of the Common Life," as the associates were called, became immensely popular. In a short time they counted 100 communities, among which there were some of women. They encountered great opposition from the mendicant orders, who sought to identify them with the Beguins, and also from the "Brethren of the Free Spirit;" but Gerhard defended himself with great skill, and obtained the formal sanction of Gregory XI. in 1376. During a visit to Ruysbroek he resolved to give to his order the rule of the canons regular, and shortly afterward on his deathbed recommended this change to Radewyn. The first monastery of canons regular was established in 1386 at Windesheim near Zwolle, and the order, thenceforward bearing the name of Windesheim, numbered in 1460 upward of 150 monasteries. The corrected text of the Bible published at Windesheim, from collated manuscripts of the version of St. Jerome, was approved by the popes and used as a chief authority in the edition of Sixtus V. The school of Deventer belonging to this order produced Thomas à Kempis, the reputed author of the "Imitation of Christ."

**GROS, Antoine Jean**, baron, a French painter, born in Paris, March 16, 1771, died about June 25, 1835. He was educated in the school of

David. "Bonaparte on the Bridge of Arcole," painted in 1801, first brought him into notice; but the "Plague at Jaffa," with Napoleon visiting the sick, exhibited in 1804, excited an extraordinary enthusiasm. The artist was placed at the head of living painters, and his picture was crowned with wreaths of palm. Gros next painted in rapid succession, and in a similar manner, immense pictures of the "Battle of Aboukir," the "Battle of the Pyramids," "Napoleon visiting the Field of Eylau after the Battle," the "Battle of Wagram," and other subjects suggested by events of the first empire. In France his chief work is considered to be the cupola of Ste. Geneviève at Paris, begun in 1811, exhibiting the saint protecting the throne of France, represented by Clovis, Charlemagne, St. Louis, and Louis XVIII. The picture covers an immense space, and is correct in design, but defective in color and expression. The artist received for it 150,000 francs, and the title of baron. Toward the close of his life his style deteriorated so greatly that his pictures were very severely criticised. He made a last attempt to compete with the new romantic school in his "Hercules and Diomedes;" failing in which, he closed his studio, exclaiming "that he knew no misfortune greater than to survive oneself." Soon after his body was found in the Seine near Meudon. It was supposed that he drowned himself in a fit of temporary insanity.

**GROS, Jean Baptiste Louis**, baron, a French diplomatist, born at Ivry-sur-Seine, Feb. 8, 1793. He entered the diplomatic service in 1823, was made a baron in 1829, and became secretary of legation in Mexico, and in 1834 chargé d'affaires at Bogotá. Afterward employed in various missions in South America, he distinguished himself by his tact in the settlement of the complications with the La Plata states. In 1849 he went to London to reconcile the English cabinet with the French expedition to Rome. The delicate question in respect to the Franco-Spanish boundary, which had been in abeyance for several centuries, was satisfactorily settled by him, after protracted negotiations at the convention of Bayonne, Dec. 2, 1856. In 1857 he was appointed ambassador extraordinary to China, where he coöperated with Lord Elgin during the capture of Canton and in the government of that city. He signed a treaty of peace with China at Tientsin in June, 1858, and on Nov. 6 a treaty of commerce and amity with Japan. He participated in the final operations of the French and English expedition on the Pei-ho against China in August, 1860, and in the conclusion of another treaty of peace (Oct. 25). In November, 1862, he became ambassador in London, but retired from the service in October, 1863.

**GROSBEAK**, the name of many conirostral birds of the finch family, and subfamily *coccothraustinæ* and *spizinae*, or hawfinches, found in all parts of the world. One of the handsomest of the American species is the pine gros-

beak (*pinicola Canadensis*, Cab.), classed by Gray among the bullfinches. In this genus the bill is short, stout, and much curved, and the base of the upper mandible nearly concealed by bristly feathers; the wings moderate, the second and third quills the longest; the tail shorter than the wings, broad and nearly even; tarsi as long as the middle toe, strongly scutellated, and the claws long and sharp. The length of the pine grosbeak is  $8\frac{1}{2}$  in., and the extent of wings 14; the bill and legs are black; the general color of the plumage is bright carmine, with grayish brown centres to the feathers of the back; the loreal region, lower jaw, sides, and lower parts, light gray; wings blackish brown, with two white bands, the outer edge of the quills also white. The female is ash-gray and brownish above, with yellow tinges below, and on the head, rump, and upper tail coverts; the young resemble the female, but are browner. This bird inhabits arctic America, coming as far south as Pennsylvania in severe winters. It is a charming songster, singing toward sunset, and in captivity during the night; it is easily kept in cages, and will eat most kinds of seeds, berries, and fruits, becoming very familiar; in its wild state it feeds on the buds and seeds of various trees, especially of the firs. The flight is undulating and direct, and they alight on the topmost branches, from which they gradually descend; they are not shy, and are easily approached, especially while bathing. The nest is made of sticks, at a small distance from the ground, and lined with feathers; the eggs are generally four, and white. Other species are found in the pine forests of Europe and Asia;

Evening Grosbeak (*Hesperiphona vespertina*).

1. Male. 2. Female.

the *P. enucleator* of Europe is smaller with a less stout bill, narrower tail, and less white on the wings.—The evening grosbeak (*hesperiphona vespertina*, Bonap.) is characterized by an enormous vaulted bill, of a greenish yellow color, much curved at the tip; the wings are

long and pointed; the tail short, and its feathers narrow; the length is 8 in. The anterior half of the body is yellowish olive; outer scapulars, band over eye, axillaries, and middle under wing coverts, yellow; crown, tibiae, wings, upper tail coverts, and tail, black. It is found in the northwest as far east as Sault Ste. Marie, and on the Pacific coast, especially about the Columbia river; from its abundance in the northern maple groves, it is called by the Indians sugar bird. The habits are those of the preceding species; they are noisy all day, and not in the evening only, as their name would indicate; their notes are harsh and screaming. The females have the head and back brownish, with yellowish ash rump, upper tail coverts spotted with white, and less white on the wings.—The rose-breasted grosbeak (*guiraca Ludoviciana*, Swains.) has a very thick, slightly arched bill, pointed wings longer than the even tail, and the tarsi shorter than the middle toe. The length is  $8\frac{1}{2}$  in.; the general color above is glossy black, with the breast, axillaries, and under wing coverts carmine; the rest of lower parts, rump, upper tail coverts, middle wing coverts, spots on the wings, base of primaries and secondaries, and patch on the end of the inner webs of the outer three tail feathers, pure white. The female is brownish above, with yellowish marks and tinges. Its song is soft, clear, and sweet, and in captivity prolonged into the night. It is found in the eastern states, as far west as Missouri, and south to Guatemala; it feeds on young and tender buds and seeds. Other species are the black-headed grosbeak (*G. melanocephala*, Swains.), found on the high central plains from Yellowstone river to the Pacific and on the table lands of Mexico, and the blue grosbeak (*G. caerulea*, Linn.), found in the southern states and across the continent.—For the cardinal grosbeak, see CARDINAL BIRD.

**GROSE, Francis**, an English antiquary, born at Greenford, Middlesex, in 1731, died in Dublin, May 6, 1791. His first work, "Views of Antiquities in England and Wales," came out in numbers, and was completed in 1787. In 1789 he went to Scotland to illustrate the antiquities of that kingdom. The first number of his work on this subject appeared in 1790. While in Scotland he became acquainted with Burns, who celebrated his convivial qualities in two ballads. Grose had few qualifications for an antiquary, but produced a number of works besides those above mentioned, the chief of which are: "Guide to Health, Beauty, Riches, and Honor" (London, 1783); "Classical Dictionary of the Vulgar Tongue" (1785); "Treatise on Ancient Armor and Weapons" (4to, 1785, to which he added a supplement in 1789); "Provincial Glossary" (1787); "Military Antiquities" (2 vols. 4to, 1786-8); "Rules for Drawing Caricatures" (1788).

**GROSEILLIERS, Médard Chouart de**, a French explorer of the 17th century. He was an early emigrant to Canada, where he married the daughter of Abraham Martin, king's pilot.

About 1660 he penetrated westward to the territory of the Sioux. He made his way from Lake Assiniboine to James bay, and, failing to induce Quebec merchants to occupy Hudson bay, went to England, and in 1663 led thither an English vessel commanded by Gillam, a New Englander. He subsequently returned to the French service and aided to break up the English posts in the bay, which he explored, naming the rivers that flow into it.

**GROSS, Samuel D.**, an American surgeon, born in Northampton co., Pa., July 8, 1805. He received his medical degree in 1828, and began practice in Philadelphia, devoting his leisure to study and to the translation of French and German medical works, as Holland's "General Anatomy," Hatin's "Manual of Obstetrics," Hildenbrand on "Typhus Fever," and Taver-nier's "Operative Surgery." His first original work was a treatise on the "Diseases and Injuries of the Bones and Joints" (1830). In this occurs the first account of the use of adhesive plaster as a means of extension in the treatment of fractures. In 1833 he became demonstrator of anatomy in the medical college of Ohio, and removed to Cincinnati; and in 1835 he became professor of pathological anatomy in the medical department of the Cincinnati college, where he delivered the first systematic course of lectures on morbid anatomy that had ever been given in this country, and composed the first systematic treatise on the subject ever published in the United States, "Elements of Pathological Anatomy" (2 vols. 8vo, Boston, 1839; 3d ed., 1857). In 1840 Dr. Gross removed to Louisville, Ky., having been elected professor of surgery in the university of that city. In 1850 he accepted the professorship of surgery in the university of New York, but at the end of the session returned to Kentucky, where he was soon restored to his chair. In 1856 he was called to Jefferson medical college in Philadelphia. Dr. Gross was chosen president of the American medical association in 1867, and in 1870 presided over the teachers' convention at Washington for the improvement of medical education. He is a member of many American and European societies, and has received the degree of LL. D. from Jefferson college of Pennsylvania, and that of D. C. L. from Oxford university (1872). Besides the works already mentioned, he is the author of a monograph on "Wounds of the Intestines" (1843); "Foreign Bodies in the Air Passages" (1850); "Diseases, Injuries, and Malformations of the Urinary Organs" (1851); "Report on the Causes which retard the Progress of American Medical Literature" (1856); "System of Surgery, Pathological, Diagnostic, Therapeutic, and Operative" (2 vols. 8vo, 1859; 3d ed., revised, 1864; translated into French, Dutch, and Russian); "Lives of Eminent American Physicians and Surgeons," and "Manual of Military Surgery" (1861). In conjunction with Dr. T. G. Richardson, he founded and for five years ed-

ited the "North American Medico-Chirurgical Review."

**GROSSE, Julius Waldemar**, a German poet, born in Erfurt, April 25, 1828. He studied at Magdeburg and Halle, and devoted himself to art at Munich, but became a journalist, and in 1870 secretary of the Schiller institution at Weimar. He has published many novels, dramas, and poems. Among the novels are *Maria Mancini* (2 vols., Stuttgart, 1869; 2d ed., 1871), *Ein Revolutionär* (1869; 2d ed., 1871), and *Der neue Abälard* (Leipsic, 1871). His *Gesammelte dramatische Werke* appeared in Leipsic in 1870, in 7 vols., and a complete edition of his poems, including the exquisite piece *Das Mädchen von Capri*, in Berlin in 1871 *et seq.* He published a volume of patriotic poems, *Wider Frankreich*, in 1870.

**GROSSENHAIN**, or **Hain**, a town of Saxony, on the Röder, 18 m. N. N. W. of Dresden; pop. in 1871, 10,488. It has pleasant gardens, several churches, many schools, and extensive manufactories of cloth, cotton, prints, &c. The town was strongly fortified in the middle ages, when it belonged to Bohemia. A great fire broke out July 6, 1540, in a nunnery, said to have been the work of the inmates, who were incensed by the proposed abolition of the institution; and the conflagration consumed the greater part of the town, and also the castle, which was afterward rebuilt, and is now used as a manufactory. After great vicissitudes during the thirty years' war, and in the war with Sweden, it was desolated by another fire, July 8, 1744, which spared only about 40 houses. The town has gradually recovered from its misfortunes, and its population and industry are steadily increasing.

**GROSSETESTE, Greathead, or Gronthead** (Lat. CAPITO), **Robert**, a British theologian, born at Stradbroke, Suffolk, about 1175, died at Buckden, Oct. 9, 1253. He was educated first at Oxford and Paris, became a professor in the latter university, was appointed archdeacon of Chester in 1210, and was successively archdeacon of Wilts, Northampton, and Leicester, prebendary of Clifton, lecturer on divinity in the first Franciscan school at Oxford, and chancellor of the university (*rector scholarum*). In 1232 he resigned all his preferments except the prebend of Clifton, and wrote a work in defence of the Jews. In 1235 he was consecrated bishop of Lincoln, and opened in his residence a school for young noblemen, for whom he composed the book entitled *De Moribus Pueri ad Mensam*. He removed all scandalous and inefficient pastors, and refused institution to pluralists, to clergymen employed in courts of judicature or in the collection of the revenue, and to all who were unable to reside on their benefices. Besides the harassing and expensive lawsuits arising from his reforms, he was compelled to go to Rome in 1245 to plead his own cause against the complaints of his chapter, sustained by Boniface, archbishop of Canterbury. He succeeded there, and after his re-

turn to England his chapter submitted, and he visited the convents and monasteries, deposing negligent or inefficient superiors, and enforcing the observance of monastic rules. He opposed the royal extravagance and favoritism, contended in parliament against the exactions of the king, and resisted the intrusion of foreigners into English livings. On a second visit to Lyons in 1250, he presented to Innocent IV. a memorial on the evils of the church, which the pope ordered to be read in the consistory of cardinals. Returning to England, Robert was dissuaded by his friend Adam de Marisco from resigning his bishopric, and soon afterward he refused to induct into a rich benefice an Italian ignorant of English, while he excommunicated an unworthy nominee of the king's, and placed an interdiction on the church to which he had been nominated. In the parliament of London, Oct. 13, 1252, the king having presented a demand for a new subsidy, backed by a papal bull, Grosseteste united the entire body of the clergy in opposition to it. He also addressed an appeal to the lords and commonalty to suppress by statute the appointment of foreigners to preferment within the kingdom. One of his last acts was to refuse carrying out a provision sent him by the nuncio, promoting to a prebend in the church of Lincoln Frederick of Louvain, the nephew of Innocent IV. The story, says Lingard, that Grosseteste died under an ecclesiastical sentence rests on questionable authority. The catalogue of his works contains treatises on almost every branch of science; it fills 23 closely printed quarto pages in Pegge's "Life of Grosseteste" (4to, London, 1793). No complete collection of his works exists. Among the principal are: *Rupertus Lincolniensis Opuscula dignissima* (fol., Venice, 1514); *Compendium Sphaerae Mundi* (Augsburg, 1483; fol., Venice, 1518; and several other editions; translated into English); "Testament of the XII. Patriarchs" (12mo, London, 1577, with woodcuts; several times reprinted); "A Treatise of Husbandry," or "The Buke of Husbandry," according to Wynkin de Worde's edition; *De Cessatione Legalium* (4to, London, 1652; 2d ed., 8vo, 1658); "Castell of Love," edited by Weymouth (1864); and "Letters and Treatises," edited by H. R. Luard (1862). A life in Latin verse by Ricardus Bardeniensis is to be found in Wharton's *Anglia Sacra*, vol. ii. See also his "Life and Times," by G. G. Perry (London, 1871).

**GROSSETO.** I. A province of central Italy, in Tuscany, bounded W. by the Mediterranean; area, 1,712 sq. m.; pop. in 1872, 107,457. The most important river is the Ombrone. It is the least productive province of Tuscany, the soil consisting partly of sterile mountain, partly of marshes, and only a small portion of it being capable of cultivation. Both agriculture and manufactures are unimportant. Among the chief products are sugar, lumber, coal, and potash. II. A town, capital of the province, in the plain of the Ombrone, 70 m. S. by W.

of Florence; pop. about 6,500. It is the seat of a bishop, and has a large cathedral and an artesian well. During summer most of the inhabitants leave the town to escape the exhalations of the Maremma.

**GROSS-GLOGAU.** See GLOGAU.

**GROSSWARDEIN** (Hungarian, *Nagy-Várad*), a town of Hungary, in the county of Bihar, on the Swift Körös, in a beautiful but somewhat marshy plain on a branch of the Pesth and Debreczin railway, 134 m. E. by S. of Pesth; pop. in 1870, 28,698. It is the seat of a Roman Catholic and a Greek Catholic bishop, has 16 Catholic, two Greek, and three Protestant churches, several convents, a Greek Catholic diocesan seminary, an academy of law, a gymnasium, two normal schools, several orphan houses and other charitable institutions, and several distilleries. The peace between John Zápolya and Ferdinand I. was concluded here in 1538. In the neighborhood is the watering place Hajó.

**GROS VENTRES** (Fr., Big Bellies), a name applied to two Indian tribes of different origin: 1, the Gros Ventres of the Missouri, or Minnetaries (see MINNETARIES); 2, the Gros Ventres of the prairies. The latter tribe, dwelling between the Milk and Missouri rivers, are a part of the Arrapahoes. They say that they came from the north and joined the Arrapahoes only temporarily; but the language is said to be the same, showing a common origin. Their separation from the Arrapahoes took place early in this century according to some, or at the beginning of the last century according to others. Wandering eastward, they met and fought the Sioux and then struck north. They next joined the Crows, but were plundered by that tribe, who killed many, carrying off their women and arms. Then they wandered for several years, plundering trading posts at the north, but were driven off by the Kootenais, and finally, about 1824, settled near Milk river, where the Blackfeet in a manner adopted them, giving them horses. The traders supplied guns and ammunition. They soon became wealthy, as well as very independent and hostile to the whites. About 1830 they were estimated at 430 lodges, containing nearly 3,000 souls. Attempts were made by Father De Smet and other Jesuits to Christianize them as early as 1846, but with little success. Treaties were made with them at Fort Laramie in September, 1851, at the Judith in 1853 and in October, 1855, and at Fort Benton in November, 1865, some of which were never ratified. The Gros Ventres have remained peaceful since the treaties. In 1854 they became hostile to the Blackfeet, who had murdered and robbed a Gros Ventre. In 1862, with the Crows, they made war on the Piegans, a Blackfoot tribe; but peace was made between them by Agent Upton at Fort Benton in February, 1864. They soon after lost severely by measles, and in 1867, having again gone to war with the Piegans, were defeated near Cypress mountains with a loss of

300 men, nearly all their horses and many of their women and children being taken. The next year they ceded their lands for an annuity of \$35,000 in goods, by a treaty which was not immediately ratified, although they were placed on a reservation on Milk river with a part of the Crows. In 1870 their numbers were reduced to 1,300 by smallpox, and they were plundered by the Sioux, who killed many of their people. They were then joined by their kindred the Arrapahoes, and by the northern Cheyennes, who wished to reside permanently with them. The greatest chief of later days was Farnasee or Sitting Squaw, a tall, athletic man, the bravest of his tribe and a great friend to the whites. They are divided into bands, each under a hereditary chief or a band leader chosen for his valor. They have comfortable lodges built by their women, large enough to accommodate 100 persons. One part is assigned to their horses, dogs, cattle, and chickens, while another is for sleeping apartments. The Gros Ventres now occupy a portion of the Blackfoot reservation of 17,000,000 acres in Montana, and receive from government annually \$35,000 in such goods as the president may from time to time determine are necessary, pursuant to the treaty of July 13, 1868.

**GROTE, George**, an English historian, born at Clay Hill, Beckenham, Kent, Nov. 17, 1794, died in London, June 18, 1871. He was educated at Charterhouse school, and in 1809 became a clerk in his father's bank. His leisure hours were given to literature and political studies. He was a liberal in politics, inclining to radicalism, and his first literary production was a reply to an article by Sir James Mackintosh in the "Edinburgh Review" on parliamentary reform. It was published anonymously in pamphlet form in 1821, and he wrote also a small work on "The Essentials of Parliamentary Reform." He studied political economy in the school of Mr. James Mill, and was influenced in philosophy by the theories of Comte. He began to collect materials for his history of Greece in 1823, but was drawn away from this project by the reform movement, and was elected to parliament in 1832 from the city of London. The principal feature of his political career was an attempt to introduce the ballot into English elections. His motion was defeated in 1833 by a vote of 211 to 106. He renewed the motion unsuccessfully the next session, and continued to advocate the measure until the close of his parliamentary service in 1841, when he resigned in order to give his whole attention to his history. While in retirement he contributed to the "Westminster Review" an article on Mitford's "History of Greece," and one to the "London and Westminster Review" on Niebuhr's "Heroic Legends of Greece." The first two volumes of his work were printed in 1846, and were received with general applause from all parties. The 12th volume was published in 1856, bringing down the subject to the end of

the generation contemporary with Alexander, the limit which the author had assigned for it. The work at once rose to a high position in literature, and several editions have been called for. It has been translated into German and French. Mr. Grote throws upon Greek history new light, and unfolds with clearness the progress of Hellenic thought. His geographical descriptions are also exact. He describes battles with minute accuracy, and is equally successful in painting Socrates disputing in the Agora, in defending the sophists, or in unfolding the bold and generous nature of Demosthenes. His philosophical speculations are sometimes abstruse and above the popular understanding; but his style is strong and bold. In 1865 he published "Plato and the other Companions of Socrates." This was to be followed by "Aristotle," which he never completed. In 1868 he succeeded Lord Brougham as president of the council of the university of London. His minor works, "with critical remarks on his intellectual character, writings, and speeches," by Alexander Bain, were published in 1873; and in the same year a sketch of his personal life was published by his widow, the authoress of a "Memoir of Ary Scheffer" (1860), and of "Collected Papers in Prose and Verse" (1862).

**GROTEFEND, Georg Friedrich**, a German philologist and archaeologist, born in Münden, June 9, 1775, died in Hanover, Dec. 15, 1853. He studied in Göttingen, officiated for some time as rector of the gymnasium of Frankfurt, founded in 1817 the *Gelehrtenverein für deutsche Sprache*, and was director of the lyceum of Hanover from 1821 to 1849. He was a contributor to Ersch and Gruber's cyclopædia, wrote on German philology and poetry, and extensively on the ancient languages and the geography of Italy, prepared several Latin grammars for the use of schools, and was the first to question the genuineness of Wagenfeld's alleged discovery of Sanchoniathon's original history of the Phœnicians. He gained reputation by deciphering the Pehlevic inscriptions of the Sassanides at Naksh-i-Rustam, near ancient Persepolis. His principal works on the subject are: *Beiträge zur Erläuterung der persopolitanischen Keilschrift* (Hanover, 1837); *Neue Beiträge zur Erläuterung der babylonischen Keilschrift* (1840); and *Anlage und Zerstörung der Gebäude zu Nimrud* (Göttingen, 1851).

**GROTIVS (DE GROOT), Hugo**, a Dutch jurist, born in Delft, April 10, 1583, died in Rostock, Aug. 28, 1645. In his 15th year he published an edition of Marcianus Capella, from the annotations of which it is evident the young editor must have been critically acquainted with the works of Cicero, Aristotle, Pliny, Euclid, Strabo, Ptolemy, and many other even more recondite authors. After three years at the university of Leyden, which he had entered at the age of 12, he was made an attaché of Barneveldt's embassy from the Dutch states to Henry IV. He returned to Holland in 1599, published

an edition of the *Phænomena* of Aratus, and began the practice of law at the Hague. In 1607 he accepted the office of advocate general for the treasury of Holland and Zealand, and shortly afterward married the daughter of an opulent family in the latter province. In 1608 he published his treatise on the freedom of the seas (*Mare Liberum*), and in 1610 a dissertation on the "Antiquity of the Batavian Republic." In 1613 he was elected pensionary of Rotterdam for life, and soon afterward was sent to England to adjust a dispute on the subject of fishery in the northern seas. The mission was not successful, and the negotiation was transferred to commissioners at Rotterdam. Grotius had adopted the principles of Arminius, and soon after his return from England became deeply involved in religious disputes. The public peace was violently interrupted through their acrimony; and various events of a short civil war led at length to the arrest of Barneveldt, Grotius, and Hoogarbets. They were tried and condemned, the first to death, and the two others to perpetual imprisonment. Their crime was defence and support of religious toleration. The castle of Loevenstein, on an island formed by the Waal and the Meuse, was selected as the prison of Grotius. His father was denied the privilege of seeing him, but his wife at length obtained permission to share his fate; and with her society and in close habits of study he found his prison by no means an intolerable home. His favorite study was theology; and its result was his celebrated annotations on the Gospels. He also wrote in Dutch the foundation of his treatise on the truth of the Christian religion, which, published afterward in Paris in Latin, became the most valued of all his works, and before the close of the 17th century had been translated into English, French, Flemish, German, Persian, Arabic, and Greek. After nearly two years' imprisonment, the escape of Grotius was effected through the wit and address of his wife. It had been her practice to send away and receive books in a chest; and observing that after a time the guards neglected to examine it in its passage to and fro, she caused Grotius to be carried out in it, March 21, 1621. Disguised as a mason, he escaped to Antwerp. His wife at first was rigorously confined, but was soon liberated. The illustrious refugee was well received at the French court, and in the course of the year became a French pensioner. He immediately published his "Apology," in vindication of his conduct, and attacking the legality of his sentence. The states general in reply outlawed the author, and forbade the reading of his memorial on pain of death. His personal safety was assured meanwhile by letters of naturalization from Louis XIII. He retired to a country seat near Senlis, and began his great work on the "Rights of Peace and War" (*De Jure Belli et Pacis*), for which he made extensive researches, and which has been translated into nearly all European languages. The author

remained more than nine years in France; and at last, through the application of friends and the entreaties of his wife, Prince Frederick Henry, who succeeded the incensed Maurice in the stadtholdership, reversed the decree of confiscation of the exile's property. In 1631 Grotius revisited Holland, but finding no security against renewed persecution, he went to Hamburg in 1632, and received immediate and pressing invitations from Spain, Portugal, Denmark, and Sweden. Gustavus Adolphus had previously made overtures to him, and after the death of that monarch Oxenstiern, the regent, prevailed upon Grotius to become Swedish ambassador at the court of France (1635). He filled this post for 10 years to the entire satisfaction of the government which he represented. The service was far from agreeable to him, but at Oxenstiern's desire Grotius remained at his post until the majority of Christina. On his visit to Stockholm in June, 1645, he was received with great honor and cordiality. He seems to have found Sweden unsuited to his health or disposition, and to have resolved to leave it. Christina at first refused him a passport, but finally dismissed him with large presents of money and plate. The vessel in which he embarked was driven into a port near Dantzic; whence, in the most tempestuous weather, he set forth in an open carriage, but was seized at Rostock by his last illness. Grotius was the first who investigated the principles of international law and attempted to reduce them to a science. Besides the works mentioned, he is the author of a great number of writings on various subjects, among which are: *Adamus Exul*, a tragedy (Leyden, 1601); *Christus Patiens*, a tragedy (1608); *Sophompaneas*, a tragedy (1617); *Defensio Fidei Catholicæ de Satisfactione Christi adversus F. Socinum* (1617); "Introduction to the Jurisprudence of Holland" (the Hague, 1631), in Dutch; *Florum Sparsio ad Jus Justinianæum* (Paris, 1642); *Via ad Pacem Ecclesiasticam* (Amsterdam, 1642); *De Origine Gentium Americanarum* (Paris and Amsterdam, 1642), and a second dissertation on the same subject (Paris, 1643); *De Imperio Summarum Potestatum circa Sacra* (1647); *Historia Gothorum, Vandalorum et Longobardorum* (Amsterdam, 1655); *Annales et Historiæ de Rebus Belgicis* (fol., 1657); *Parallelon Rerumpublicarum Libri III.* (3 vols. 8vo, Haarlem, 1801); commentaries on various portions of the Scriptures, Latin poems, and miscellaneous treatises. His letters were published in full at Amsterdam (fol., 1687). His *Opera Theologica* were published in 1679 (4 vols. fol., Amsterdam, and 3 vols. 4to, London), and his poems in 1617 (Leyden; 11th ed., Amsterdam, 1670). There are numerous English translations of the most important of his works, including the treatises *De Veritate Religionis Christianæ* and *De Jure Belli et Pacis*.—See *Étude sur la vie et les travaux de Hugo Grotius*, by Caumont (1862), and Motley's "Life of John of Barneveldt" (1874).—His bro-

ther WILLEM (1597-1662), who was a distinguished lawyer, collected and published his Latin poems, and wrote a treatise on natural law (the Hague, 1655) and lives of the jurists named in the Pandects (Leyden, 1690).

**GROTON. I.** A town of Middlesex co., Massachusetts, on Nashua and Squannacook rivers, 30 m. N. W. of Boston and 13 m. W. of Lowell; pop. in 1870, 3,584. Since the census the town of Ayer has been taken from it. Four railroads, viz., the Worcester and Nashua, the Fitchburg, the Stonybrook, and the Peterborough and Shirley, intersect at Ayer Junction (formerly Groton Junction). Groton is the seat of the Lawrence academy, which was incorporated in 1793, and owes a liberal endowment to the munificence of the Lawrence family, who are natives of this place. The academy has a library of 2,500 volumes and an endowment of \$80,000. In 1872 the number of instructors was 7, and of pupils 147, of whom 92 were males and 55 females. The town contains several saw and grist mills, manufactories of agricultural implements, paper, and leather, and 10 public schools. **II.** A town of New London co., Connecticut, on Long Island sound, at the E. side of the mouth of Thames river, and opposite New London; pop. in 1870, 5,124. It is on the Stonington and Providence railroad, the principal village being 12 m. W. of Stonington, and 62 m. by rail S. W. of Providence. There is a good harbor, and the town is interested in the coasting trade, ship building, and the fisheries. A considerable export business is carried on with New York. Mystic and Pequonock rivers flow through the town to Long Island sound, and supply valuable motive power, which is employed in running cotton mills, &c. There are foundries of brass and iron, manufactories of britannia ware and carriages, two granite quarries, and 11 public schools. The town contains a United States naval station and five post offices, viz.: Groton, Centre Groton, Poquonoc Bridge, Noank, and Mystic River. Groton is the site of Fort Griswold, memorable for the massacre of an American garrison at the time of the destruction of New London and Groton by the British troops under Benedict Arnold, Sept. 6, 1781. The British having captured the fort after a desperate resistance, the American commander, Col. Ledyard, surrendered to the officer of the detachment, and was immediately killed with his own sword, most of his men being also butchered; 85 of the Americans were killed and 60 wounded. A granite monument to commemorate this event was erected in Groton in 1830.

**GROFFO** (It. *grotta*), a natural cavern, or an artificial excavation in the earth. Among the most famous caverns particularly designated by this name is the Käsegrotte at Bertrich, Rhenish Prussia, so called from the columnar piles of blocks of basalt shaped like cheeses, in the midst of which the cave extends. Still more celebrated is the Grotta del Cane, near Pozzuoli, Naples, referred to by Pliny as one of the

class of excavations known as "Charon's ditches." It would seem from his reference that in his time the mephitic gas for which it is still remarkable was exhaled in quantity sufficient to prove fatal to human life. At the present time this forms but a shallow stratum upon the floor, in which a candle is extinguished and dogs are stifled by way of experiment. The custom of exhibiting the effect of the carbonic acid gas upon dogs has given the distinctive name to the grotto. The excavation is described as extending about 10 ft. into the base of a hill, with a width of 4 and a height of 9 ft. Prof. Silliman, in his "Notes on Europe," speaks of it as a little hole dug artificially into the foot of a hill facing Lake Agnano. The aperture is closed by a door, and the space within is barely sufficient for one person to stand erect. Into this narrow cell a dog is dragged, and placed in a depression of the floor, where he is soon narcotized by the carbonic acid. The earth is warm to the hand, and the volume of gas given out is very constant. Among other celebrated grottoes is that of the island of Antiparos. (See ANTIPAROS.)

**GROUCHY, Emmanuel**, marquis de, a French general, born in Paris, Oct. 23, 1766, died in St. Etienne, May 29, 1847. He entered the military service at the age of 14, and on the breaking out of the revolution had been for five years a lieutenant in the royal body guards. He was then placed in command of a regiment of chasseurs, served in 1792 under Lafayette, was made a brigadier general, commanded the cavalry in the army of the Alps, and contributed to the conquest of Savoy. The decree of the convention cashiering all officers who belonged to noble families suspended his career for a while. Reëntering the army as a private, he was reinstated in 1795 by a special decree and made a general of division. Being called to the army in Italy in 1798, he persuaded the king of Sardinia to abdicate and surrender Piedmont to France. In 1799, at the battle of Novi, he received 14 wounds and was taken prisoner. The battle of Marengo procured his liberation; he then joined Moreau on the Rhine, took part in the victory of Hohenlinden, and was made inspector general of cavalry. He served in 1806 and 1807 in Prussia; was governor of Madrid in 1808; assisted in 1809 in the battle of Wagram; and finally signaled himself at the battle of Borodino in 1812. On the retreat from Moscow he was placed in command of the guard selected to accompany the emperor. After the battle of Leipsic he vigorously opposed the invasion of France by the allied troops, making a stand at Brienne, La Rothière, Vauchamps, and Étoges. A wound received at Craonne, March 7, 1814, forced him to leave the army. Coldly treated by the Bourbons on the first restoration, he joined Napoleon at once on his return from Elba, and being placed in command of the army at Lyons, arrested the duke of Angou-

lème, and was made a marshal of France. He played a conspicuous part in the concluding scenes of the hundred days; at the head of a corps of the army, he marched into Belgium against the united English and Prussians, fought successfully, June 16, at Fleurus and Ligny, received orders from Napoleon to follow up Blücher and the Prussian army to prevent their joining the English, and, strictly adhering to the very letter of his orders, declined, notwithstanding the entreaties of his subordinate generals, to march toward Waterloo, June 18, and thus became the indirect cause of the defeat of the French army. Being proscribed by a royal decree on the second restoration, he came to the United States, and lived for five years in Philadelphia. An amnesty recalled him to France in 1821; and after the revolution of July, 1830, his rank of marshal was restored. He defended his conduct in several pamphlets, the most important points of which are to be found in his *Fragments historiques* (Paris, 1840).

**GROUND HOG.** See WOODCHUCK.

**GROUND NUT.** See PEANUT.

**GROUND PINE.** See HORSETAIL.

**GRONDSSEL**, the common name of *senecio vulgaris*, of the natural order *compositæ*. It is a little, weedy plant, found in waste places and in gardens from New England to Pennsylvania, adventitiously introduced from abroad. The name groundsel is derived from the Anglo-Saxon word for "ground glutton," probably in allusion to its character as a weed. It is an inconspicuous annual, and not difficult to keep in subjection. Its seeds are a favorite food of many small birds, and the flower heads are sometimes gathered for the purpose of feeding canary birds. Groundsel has no ray flowers, but in our native *senecios* the heads are mostly radiate and showy. Among the commonest of these is the golden ragroot (*S. aureus*), an elegant ornament of our wet meadows; and in the greenhouse the rich purple blossoms of *S. elegans* are much admired. The fireweed, so conspicuous upon recently burnt lands for its coarse rank growth and white silky heads, was formerly called a *senecio*, but is now put in a separate genus, and is *erecthites hieracifolia* (Raf.). *Senecios* are found in every part of the globe, especially in South Africa. Humboldt noticed some species in the upper regions of the Andes, just below the snow line. De Candolle describes nearly 600 species, of which 50 or more are natives of North America.

**GROUND SQUIRREL.** See CHIPMUNK.

**GROUSE**, the name of gallinaceous birds of the family *tetraonidæ*, characterized by a short broad bill with culmen curved; the nostrils concealed by closely set feathers in the nasal groove; wings short, concave, and rounded; tarsi moderate and densely feathered; the toes usually naked, with scaly pectinations along the edges, but feathered to the claws in the snow grouse or ptarmigans. The tail varies in length and shape, and consists of 16, 18, or 20 feathers; there is generally a bare space about

the orbits, with fringed processes above the upper lid; the hind toe is short, and slightly elevated. The old genus *tetrao* (Linn.) has been subdivided into many genera by modern systematists; it included both the grouse and the ptarmigans or moor fowl, the latter of which will be described under PTARMIGAN. The grouse are the largest of the family, robust and round-bodied, frequenting heathy woods, feeding on young shoots, tender buds, and berries, in pine and spruce forests and cedar swamps in the northern regions of America, Europe, and Asia.—In the genus *tetrao* (Linn.) and the allied *centrocercus* (Swains.), the legs are feathered as far as the basal membrane of the toes; the tail is lengthened, slightly narrowed to the somewhat rounded tip, and the shafts stiffened; no ruff on the sides of the neck. The largest species is the wood grouse or capercaillie (*T. urogallus*, Linn.), measuring nearly 3 ft. in length, and weighing about 15 lbs.; the feathers of the head and cheeks are elongated and erectile; the hind neck, back, and sides are minutely varied with black, brown, and gray; the lower breast and belly black, with a few white feathers; the fore part of breast rich glossy green, with metallic reflections. The females are much smaller, and, like the young males, are brown with black crescent marks. In size, strong hooked bill, and noble bearing, it resembles a bird of prey; it is nearly extinct in Great Britain, though it is found in Norway, Sweden, Russia, and northern Asia. It inhabits forests of pine and birch with an undergrowth of juniper; it is extremely shy, but will breed in confinement, and may be domesticated, in which state it feeds on grains and resinous twigs. This species perches in trees; the nest is placed amid brakes and underbrush; the eggs are 8 to 16, yellowish white, with darker yellow spots. The *T. hybridus* (Linn.) is generally considered a hybrid between the capercaillie and the black grouse (*T. tetrix*, Linn.); it is found in northern Europe, and is from 2½ to 2½ ft. long; the general color is black, with purple and bronzed reflections, dashes of white on the belly, and on the secondaries a spot of the same; the scapulars and wing coverts deep brown, with delicate yellowish waves; tail slightly forked, the upper coverts black, the under tipped with white. The black grouse has been described under BLACKCOCK. Among the American species is the Canada grouse, sometimes called erroneously the spruce partridge (*T. canadensis*, Linn.). It is about 16½ in. long; the prevailing color is black in the male, each feather of the upper parts waved with leaden gray; those of the sides, scapulars, and outer surface of the wings have a central white streak expanding toward the tip; the under parts are mostly uniform black, broadly tipped with white on the sides, this color sometimes forming a pectoral band; bar across base of upper mandible, spot on lower lid, line on cheeks and throat, white; quills dark

brown; tail of 16 feathers, dark brown, tipped with a band of orange chestnut half an inch wide; chin, throat, and bill black; under tail coverts black, barred and tipped with white. The female is smaller, but similar, with broader black bars above, and below barred with orange and white; the continuous black on the head and breast is wanting. They are found in the spruce forests and cedar swamps of the northern states to the arctic seas, and westward nearly to the Rocky mountains; their flesh, like that of the other grouse, is excellent, but in the winter it has the bitter flavor of the spruce on which they feed at that season. They are not very shy; when alarmed they resort to trees; the nest is made upon the ground, and the eggs, comparatively few, are varied with white, yellow, and black.—The pheasant-tailed grouse, sage cock, or cock of the plains (*centrocercus urophasianus*, Swains.), is by far the largest of the American grouse, measuring about 30 in., with an extent of wings of about 40; the tail is very long, wedge-shaped, the feathers all lanceolate, and longer than the wings; the feathers of the lower throat and sides are stiff and spiny. Above, the plumage is varied with black, brown, and brownish yellow, the coverts streaked with the latter; black below, the breast and tips of tail coverts white, the lower part of the former with black streaks; the tail has 20 feathers. It is found in the desert plains of the far west, especially about the branches of the Columbia river; it feeds on the various species of worm-wood, which impart a bitter flavor to its flesh; it is not shy, and is a poor flier; the eggs are numerous, 13 to 17, of a wood-brown color, with

is 18 in. and the extent of wings 26. Above, the color is light brownish yellow, varied with black, and with rounded white spots on the wings; below pure white, with dark V-shaped marks on the breast and sides; there are no elongated feathers on the neck, as in the next

Pinnated Grouse (*Tetrao cupido*), Female (upper figure) and Male.

species, the bill is stouter, and the tarsi are more densely feathered. It inhabits the northern prairies and plains from Illinois to Oregon. Its food consists of the buds and sprouts of the beech, willow, aspen, larch, and similar trees, and of berries; the eggs, about 13, are white, with colored spots. The pinnated grouse, prairie hen or chicken (*T. cupido*, Linn.; genus *cupidonia*, Reich.), has a tail of 18 feathers, short, truncate, and much graduated, and a tuft of long, lanceolate feathers on each side of the neck, covering a bare space capable of considerable inflation. The plumage is covered with transverse bands of white on a brown ground, the latter nearly black, and the former with a rufous tinge, above; long feathers of the throat black; different specimens vary much in color. The length is about 17 in., with an extent of wings of 28, and a weight of 3 lbs. This species, once common in the Atlantic states, is now mostly confined to the western plains; the old name in New York was heath hen. The food is acorns, buds, leaves, berries, and grains. They remain all the year in their favorite and barren grounds; in spring the males meet at break of day in what are called "scratching places," where they swell and strut with great pomp, and engage in fierce contests, uttering a peculiar sound rendered more intense by the large inflated sacs on the sides of the neck. Their flesh, as well as that of the preceding species, is excellent.—The ruffed grouse, erroneously called partridge in New England and pheasant in the middle states (*bonasa umbellus*, Steph.), is familiarly known by its ruff of velvety black feathers on the sides of the neck, its broad fan-like tail of 18 feathers, partially crested head,

Cock of the Plains (*Centrocercus urophasianus*), Female (upper figure) and Male.

irregular chocolate blotches on the larger end, and about the size of those of a common fowl. The sharp-tailed grouse (*T. phasianellus*, Linn.; genus *pediocetes*, Baird) has a short, graduated tail of 18 feathers, the central pair elongated about an inch beyond the rest; the length

and tarsi naked in their lower half. The sexes are nearly alike. It is reddish brown or chestnut above, varied with lighter heart-shaped spots and streaks of light brownish yellow; below, whitish, with transverse bars of dull brown; tail tipped with gray, with a subterminal bar of black. The length is 18 in., and the extent of wings 2 ft.; it is found in the eastern states and Canadas, and probably as far as the Rocky mountains. The species of the Pacific coast, darker and with a longer middle toe, has been described as the *B. Sabinii*. The ruffed grouse prefers wooded regions, where evergreen trees and streams abound. They are rather solitary, usually seen in pairs or single, and fond of frequenting travelled paths; the males make a peculiar drumming sound, standing upon a log, inflating the body, and beating the air with short and quick strokes of the wings; this is most commonly heard in the morning and evening, but also at all times of the day. The nest is built on the ground, early in May, and the eggs, 9 to 15, are clear brownish white; the female, like other birds of the family, exhibits signs of great distress when her young brood are approached, and makes use of various well known stratagems to lead the intruder from the spot. The flight is vigorous, and accompanied by a loud whirring noise; they are easily hunted with a good dog, generally betaking themselves to a tree; they are taken in traps and snares set in their favorite paths; in severe winters they are often found frozen under the snow, into which they dive for protection, a crust having formed above them. Their flesh is excellent, and in best condition in autumn, when the partridge berries impart a peculiar aromatic flavor; in winter they are sometimes forced to eat the tender buds of the laurel, and then their flesh may possess poisonous properties so strong as to cause death in delicate persons.—The willow or white, the rock, the white-tailed, the American, and the red grouse of Europe, belong to the genus *lagopus* (Briss.), and will be described under PTARMIGAN.—The sand grouse (*pteroeles*, Temm.) represents the family of *tetraonidae* in the sandy deserts of Asia and Africa, and in some of the bare rocky plains of southern Russia. Their very long and pointed wings, with the first and second quills the longest, enable them to traverse vast distances with an ease and rapidity unnecessary in birds of the moor and forest; their bodies are light and slender, and the tail large and wedge-shaped; the tarsi robust, long, covered with feathers in front and on the inside; the short and stout toes, united at the base by a prominent membrane, enable them to run lightly over the soft sand. Their prevailing colors are shades of brown, gray, and ochreous yellow, like that of the deserts in which they live. The banded sand grouse (*P. arenarius*, Pall.), found occasionally in Europe, has the belly deep brownish black, with a spot of the same on the throat and a band on the breast; the female is paler,

without the patch on the throat. The food consists of seeds, bulbs, and insects; the nest is made upon the ground, and the eggs are only

Banded Sand Grouse (*Pterocles arenarius*).

four or five in number.—The grouse are polygamous, and very tyrannical in their gallinaceous harems; after the short love season the males desert the females and lead a solitary life, caring for neither mate nor progeny.—The name of partridge cannot properly be given to any grouse; the genus *perdix* (Briss.), and indeed the whole family of *perdicinae*, are not found in America; the term is equally inapplicable to the quail family.

**GROUSSET, Paschal**, a French communist, born in Corsica about 1845. He is the son of the president of a college, and early went to Paris to study medicine, but became a journalist, and eventually joined Rochefort in the *Marseillaise* and wrote for the *Revanche*, a Corsican journal. Prince Pierre Bonaparte having challenged Rochefort for articles which Grousset had written, the latter sent Victor Noir and Ulrich de Fonvielle as his seconds to the prince, by whom Noir was killed, Jan. 10, 1870. The prince was tried and acquitted, and Grousset was arrested and fined for his violent articles in the *Marseillaise*. He became director of that journal after the proclamation of the republic, Sept. 4, but suspended its publication in consequence of Rochefort's disavowal of its tendency. The fiercest of the various journals which he next edited was *La Bouche de Fer*. He became the foreign minister of the central committee after the insurrection of March 18, 1871, and on being elected to the commune he continued to hold the same position, and in April joined the new executive commission. He was arrested on June 3, disguised in the attire of his mistress, betrayed by his bearing, which had made him conspicuous as the most fashionable member of the commune. He was transported to New Caledonia in 1872, but escaped in March, 1874.

**GROVE, Sir George**. See supplement.

**GROVE, Sir William Robert**, an English physician, born in Swansea, July 14, 1811. He graduated at Oxford in 1833, was called to the bar in 1835, and from 1840 to 1847 was professor of natural philosophy at the London institution. In 1853 he was made queen's counsel, and afterward vice president of the royal society. His scientific researches have been chiefly in

the field of electricity; and his contributions to philosophical publications, principally on this subject, are very numerous. A few only of his original researches can here be noticed. In 1839 he described in the "Philosophical Magazine" his new battery, much more powerful than any previous one, and still in general use under his name, in which platinum is substituted for the copper plate, and nitric for sulphuric acid. About the same time he made the discovery that if two pieces of gold are placed, one in a cell of nitric, and the other in one of hydrochloric acid, and the cells separated by an earthenware partition, no chemical action takes place; but if the two pieces are connected by a metallic wire, they are immediately attacked by the acids. In 1841 he described in the same journal a method of engraving the daguerreotype plate by galvanic action. In January, 1842, Mr. Grove delivered a lecture before the London institution on the progress of physical science, in which he first announced what is now generally known as "the theory of the correlation of forces." In 1847 he published his essay on "The Correlation of Physical Forces," which has passed through several editions, and has been translated into various European languages. Among his numerous discoveries not already mentioned are the decomposition of water into free oxygen and hydrogen, the electricity of the flame of the blowpipe, electrical action produced by proximity without contact of dissimilar metals, molecular movements induced in metals by the electric current, and the conversion of electricity into mechanical force. He was president of the British association in 1866, was appointed a justice of the court of common pleas in 1871, and was knighted in 1872.

**GROVETON.** See BULL RUN.

**GRUBER, Johann Gottfried**, a German cyclopædist, professor of philosophy in the university of Halle, born in Naumburg, Prussia, Nov. 29, 1774, died in Halle, Aug. 7, 1851. He wrote nearly 30 works on historical, critical, and imaginative subjects, and was joint editor with Ersch of the *Allgemeine Encyclopädie der Wissenschaften und Künste*. (See ERSCH.)

**GRÜN, Anastasius.** See AUERSPERG, A. A.

**GRÜNBERG**, a town of Prussian Silesia, in the government of Liegnitz, 50 m. S. E. of Frankfort-on-the-Oder; pop. in 1871, 11,091. It is walled and surrounded by suburbs. Its environs are noted for their vineyards. It manufactures woollens, linens, printed cottons, silk goods, leather, and champagne wine.

**GRUNDTVIG, Nicolai Frederik Severin**, a Danish writer, born at Udby, Seeland, Sept. 8, 1783, died in Copenhagen, Sept. 2, 1872. He studied theology at Copenhagen, and in 1810 began to preach in that city. His doctrines offended the clergy, and he finally separated from the orthodox Lutheran church and became the head of a distinct school opposed to centralization in church government. In 1848 he engaged in politics, and became an influential leader in

the diet of the Danish party, in opposition to German influence and in favor of a union of the Scandinavian nations. Grundtvig published two collections of sermons, a collection of hymns, and many historical works, among which are: *Nordens Mythologie* (1808; 2d ed. revised, 1832); *Kort Begreb af Verdenskrønike* ("Short Sketch of the History of the World," 1812); translations of Saxo Grammaticus and Snorro Sturleson (6 vols., 1818-'22); *Haandbog i Verdenshistorien* ("Manual of Universal History," 4 vols., 1833-'43). Among his poetical works are: *Optrin af Kampelivets Undergang i Nord* (2 vols., 1809); *Roeskilde-Rim* (1814); and *Nordiske Smaadigte* (1838). From 1816 to 1820 he published a literary journal, *Dannevirke*, and from 1848 to 1851 a political weekly, *Danskeren*. During the Schleswig-Holstein war he wrote spirited songs for the Danish cause.

**GRUNDY. I.** A S. E. county of Tennessee, drained by Collins river; area, 300 sq. m.; pop. in 1870, 3,250, of whom 137 were colored. It has a mountainous surface and a fertile soil. The chief productions in 1870 were 12,131 bushels of wheat, 73,373 of Indian corn, 11,242 of oats, 10,218 of potatoes, and 47 bales of cotton. Capital, Altamont. **II.** A N. E. county of Illinois, drained by Illinois river; area, 430 sq. m.; pop. in 1870, 14,938. It is intersected by the Chicago, Rock Island, and Pacific, and the Chicago and Alton railroads, and by the Illinois and Michigan canal. The surface is generally level, and the soil is fertile. Timber is not abundant, but bituminous coal has been found. The chief productions in 1870 were 21,850 bushels of wheat, 295,971 of Indian corn, 269,332 of oats, 51,451 of potatoes, 438,309 lbs. of butter, and 37,116 tons of hay. There were 7,264 horses, 6,770 milch cows, 12,575 other cattle, 3,845 sheep, and 8,269 swine; 2 manufacturing of agricultural implements, 4 of carriages and wagons, 3 of saddlery and harness, 2 flour mills, 1 tannery, 1 currying establishment, and 1 distillery. Capital, Morris. **III.** A N. E. central county of Iowa, watered by branches of Red Cedar river; area, about 500 sq. m.; pop. in 1870, 6,399. It consists chiefly of prairies; the soil is fertile. The chief productions in 1870 were 621,322 bushels of wheat, 345,717 of Indian corn, 201,733 of oats, 13,360 of barley, 38,995 of potatoes, 154,107 lbs. of butter, and 14,576 tons of hay. There were 3,667 horses, 2,881 milch cows, 2,995 other cattle, 2,972 sheep, and 4,111 swine. Capital, Grundy Centre. **IV.** A N. county of Missouri, drained by Weldon and other rivers, and consisting chiefly of fertile prairies; area, 462 sq. m.; pop. in 1870, 10,567, of whom 115 were colored. The chief productions in 1870 were 63,242 bushels of wheat, 13,138 of rye, 427,818 of Indian corn, 186,184 of oats, 37,666 of potatoes, 123,251 lbs. of butter, 48,207 of wool, and 7,100 tons of hay. There were 5,241 horses, 4,137 milch cows, 8,853 other cattle, 18,896 sheep, and 19,110 swine. Capital, Trenton.

**GRUNDY, Felix**, an American statesman, born in Berkeley co., Va., Sept. 11, 1777, died in Nashville, Tenn., Dec. 19, 1840. He was educated for a physician, but studied law, was admitted to practice in 1798, and soon acquired reputation as an advocate. In 1799 he was a member of the convention to revise the constitution of the state, and was elected to the legislature, and in 1806 was appointed one of the judges of the supreme court of errors and appeals. Soon afterward he was appointed chief justice of Kentucky, which office he resigned in 1808, and removed to Nashville, Tenn., where he soon ranked as the head of the Tennessee bar. He was elected to congress in 1811, and efficiently supported Madison in the war with Great Britain. He was reelected in 1813, but declined to be a candidate in 1815. In 1829, and again in 1833, he was elected a senator of the United States, and was among the most prominent supporters of President Jackson. In 1838 Van Buren appointed him attorney general of the United States. In 1840 he resigned, and was reelected to the senate, but died before taking his seat.

**GRUNER, Wilhelm Heinrich Ludwig**, a German engraver, born in Dresden, Feb. 24, 1801. He studied in Italy, Spain, France, and England. His first effort, an engraving of a Spanish shepherd, after Velasquez, was followed by a portrait of Mengs, and engravings of Madonnas after Raphael, and of the paintings of Giulio de' Medici and Moses by Murillo. In Rome he published in 1839 a series of engravings, under the title *I mosaici della capella Chigi*, and soon afterward he copied the frescoes in the hall of Heliodorus. For the Berlin museum he prepared, at the request of the king of Prussia, a series of engravings after the cartoons of Raphael at Hampton Court. A disease of the eyes preventing him from working with the burin, he executed many frescoes by order of Prince Albert, and published "Fresco Decorations and Stuccoes," &c. (London, 1844), and "Decorations of the Garden Pavilion in the Grounds of Buckingham Palace" (1846), accompanied with a text by Mrs. Jameson. Resuming his labors as an engraver, in 1848 he published "Ornamental Designs for Decorators and Manufacturers," and in 1850 "Specimens of Ornamental Art." He took a part in the decoration of the London crystal palace and in the illustration of Layard's "Nineveh." His "Raphael Caryatides from the Vatican" appeared in 1852. Between 1854 and 1856 he superintended the decoration of the new wing of Buckingham palace and of Osborn castle. In 1858 he became director of the society of engravers at Dresden, and professor of engraving at the academy in that place. About the same time he published "The Bass Reliefs on the Façade of the Cathedral at Orvieto."

**GRÜTLI**, or **Rüdtli**, a locality of Switzerland, in the canton of Uri, 5 m. S. W. of Schwytz, consisting only of a small space occupied by a meadow with a few cottages and walnut and

chestnut trees, but celebrated as the cradle of Swiss liberty, and as the spot where Stauffacher, Walther Fürst, and Arnold of Melchthal met, according to tradition, during the night of Nov. 7-8, 1307, with 30 followers, and formed a Swiss league against Austrian tyranny. It is at the N. E. declivity of the Seelisberger or Niederbauer Kulm, a mountain about 6,000 ft. high, near the watering place of Seelisberg, on the lake of Lucerne, and is easily accessible by boats from steamers plying between Lucerne and Flüelen. About 1 m. N. of it is the Mythenstein, a lofty rock on which is the inscription *Dem Sänger Tells, Friedrich Schiller, die Urcantone*, 1860. Tell's chapel is 3 m. from Grütli. The land became national property in 1858, having been purchased by the Swiss patriotic association for 55,000 francs.

**GRUYÈRE**, or **Gruyères** (Ger. *Greizer*), a village of Switzerland, in the canton and 15 m. S. by W. of the city of Fribourg; pop. about 1,000. It stands on a hill crowned by an ancient and very perfect feudal castle, and gives name to a celebrated kind of cheese. (See CHEESE, vol. iv., p. 352.)

**GRYPHIUS, Andreas**, a German poet, born at Glogau, Silesia, Oct. 11, 1616, died there, July 16, 1664. He studied at Dantzic and Leyden, travelled in France and Italy, and spent the last part of his life as syndic of Glogau. His tragedies are stilted imitations of the Greek and Latin dramas, but his comedies have much merit, and a new edition of some of them appeared in 1855. He also wrote a Latin religious epic, *Olivetum*. His select poems are contained in W. Müller's collection of German poets of the 17th century (2 vols., Leipsic, 1822).

**GUACHARO**, a fissirostral bird of the family *caprimulgidae* or goatsuckers, subfamily *steatorninae* or oil birds, and genus *steatornis* (Humboldt). There is only one described spe-

Guacharo Bird (*Steatornis Caripensis*).

cies, the *S. Caripensis* (Humb.); it is nocturnal, living in great numbers in the cave of Guacharo in Venezuela, described by Humboldt. The family and genus are treated in the article GOATSUCKER. The bird is about the size of the common fowl, with a curved and toothed

bill; the color is dark bluish gray, with minute streaks and spots of deep brown, and white spots bordered with black on the head, wings, and tail; the spread of the wings is about  $3\frac{1}{2}$  ft. The food is vegetable, principally seeds and hard fruits, upon which they grow so fat that the Indians destroy great numbers for the sake of their oil, which they use in preparing their favorite dishes. They would long ago have been exterminated, were it not for the superstitious fears of the natives, who do not dare to penetrate far into their caves, terrified by the shrill cries of the vast multitudes when disturbed by the torches of explorers.

**GUACO**, or **Huaco**, a name given in the tropical regions of America to several plants used as antidotes for the bites of poisonous snakes. *Aristolochia guaco* is said to be the one most in repute; and so great is the confidence in its efficacy that the Indians and negroes of parts of South America will not undertake a journey without carrying some of the dried leaves of the plant. The aristolochias are generally climbing plants, with grotesquely formed and often larid-colored flowers. Two North American species of *aristolochia* were found by the early settlers to be in use among the aborigines for the same purposes as the South American one, and they still retain the name of Virginia snakeroot. The name guaco is also given to one of the composite family, the *mikania guaco*, described by Humboldt and Bonpland as a plant with twining stems, leaves ovate, pointed, and dentate, and flowers in opposite, axillary corymbs. The fresh leaves are bruised and applied to the wound, and they are also made to yield an infusion which is drunk at the same time. The preparation has a bitter, disagreeable taste, and acts as a mild tonic and a gentle stimulant to the secretions.

**GUADALAJARA**, a city of Mexico, the second in importance of the republic, capital of the state of Jalisco, 275 m. N. W. of the city of Mexico; pop. about 70,000. It stands on the left bank of the Rio Santiago, in the midst of a vast barren plain. The streets are wide, and the houses, which are generally but two stories high owing to the frequency of earthquakes, are neat and handsome. There are 14 public squares, the finest of which, the Plaza de Armas, is very spacious. On its north side is the cathedral, completed in 1618. The cupolas of both towers were destroyed by the great earthquake of May 31, 1818. The governor's

palace occupies the whole of the east side of the plaza, and the two remaining sides form each an uninterrupted arcade, with brilliant shops and bazaars. Besides the cathedral there are many churches and convents. The Alarcon theatre, of modern construction, is large

Plaza de Armas, Guadalajara.

and elegant. There are two hospitals, a mint, two prisons, a university, a seminary, a school of design, a collegiate and several common schools, and many private schools. There are manufactories of *serapes*, a kind of shawl, paper, earthenware, and leather. The climate is temperate.—The town was founded in 1532 by Cristóbal de Oñate, under the name of Santo Espiritu. It became the capital of New Galicia in 1543, and an episcopal see in 1549.

**GUADALAJARA**. **I.** A province of Spain, in New Castile, bordering on the provinces of Segovia, Soria, Saragossa, Teruel, Cuenca, and Madrid; area, 4,869 sq. m.; pop. in 1870 (estimated), 208,638. The surface toward the north and east is mountainous, particularly in the district of Atienza, but in the south and west it expands into large elevated plains. The chief rivers are the Tagus, Tajuña, and Jarama. In the district of Tamajón the soil is well adapted to corn; in that of Alcarria the vine and olive also grow; while the mountain districts are suited to pasturage. The most important minerals are iron, lead, and coal. Mines of iron have been worked from the time of the Romans. **II.** A city, capital of the province, on the Henares river, 33 m. N. E. of Madrid; pop. about 8,000. It has a large Roman aqueduct, which supplies the public fountains. There are ten churches, two hospitals, a military school, a palace of the dukes of Infantado, and manufactories of cloth.

**GUADALQUIVIR** (anc. *Bætis*), a river of Spain, which rises near the S. E. corner of the province of Jaén, flows first N. E. and N. W. and then S. W. through Andalusia, passing Andu-

jar, Villafranca, Cordova, and Seville, and falls into the Atlantic at San Lucar de Barrameda, 14 m. N. of Cadiz. It is more than 250 m. long, and is navigable for nearly 70 m. Its principal tributaries are the Guadalimar, Jandula, and Guadiato on the right, and the Guadiana Menor, Guadajoz, and Jenil on the left. The Guadalquivir drains an area of about 20,000 sq. m.

**GUADALUPE**, a river of Texas, rising in Edwards co., in the S. W. part of the state. It flows nearly E. until it enters the alluvial plain that stretches toward the gulf of Mexico, from which point it pursues a general S. course to its junction with the San Antonio, about 12 m. from its mouth in Espiritu Santo bay. Its length is about 250 m. On its banks are the towns of New Braunfels, Seguin, Gonzales, Clinton, and Victoria. The San Marcos, which enters the Guadalupe in Gonzales co. from the north, is the principal tributary. Steamers have occasionally ascended to Victoria.

**GUADALUPE**, a central county of Texas, drained by the Guadalupe river; area, 807 sq. m.; pop. in 1870, 7,282, of whom 2,534 were colored. It has an undulating surface, covered with prairies and good timber. The chief productions in 1870 were 197,889 bushels of Indian corn, 13,556 of sweet potatoes, and 2,874 bales of cotton. There were 6,859 horses, 6,061 milch cows, 51,454 other cattle, 3,262 sheep, and 11,748 swine. Capital, Seguin.

**GUADALUPE**, or *Guadalupe Hidalgo*, a small town in the republic and federal district of Mexico, about 3 m. N. of the capital, with which it communicates by two beautiful parallel roads. It owes its importance to its church, situated at the foot of the Cerro de Tepeyac, and dedicated to Nuestra Señora de Guadalupe, the patron saint of the republic, who is there represented by a gorgeous image, and whose reputed power of working miracles attracts immense numbers of pilgrims from all parts of the country. Her feast is celebrated annually with great pomp. After the defeat of Santa Anna's troops by the American forces, the treaty of peace was signed at Guadalupe, Feb. 2, 1848.

**GADELOUPE**, one of the Leeward islands of the West Indies, and the most important of those which belong to France, between lat. 15° 57' and 16° 30' N., and lon. 61° 15' and 61° 45' W.; area, including dependencies, 625 sq. m.; pop. in 1868, 152,910, three fourths of whom are colored. It consists, properly speaking, of two islands, separated by a narrow channel, not more than from 30 to 100 yards broad, called Rivière Salée or Salt river, navigable for small vessels. The western island, styled Guadeloupe proper, is 35 m. long and 18 m. wide; the eastern, called Grande-Terre, is of about the same length, but only 12 m. wide. Guadeloupe proper is of volcanic origin, and is traversed from N. to S. by a mountain range whose summit is a volcano called the Soufrière, about 5,000 ft. high. Grande-Terre is low,

flat, and marshy, composed of coralline matter and marine detritus. The climate is hot, humid, and unhealthy. Hurricanes are frequent and destructive. In 1843 there was a severe earthquake. The exports are sugar, molasses, rum, cotton, tobacco, coffee, dye woods, and copper. The imports are cotton goods, pottery, glassware, provisions, medicines, &c. In 1870 the exports to France amounted to 24,900,000 francs, the imports from France to 9,800,000 francs. The government of Guadeloupe consists of a governor, a privy council of 6, and a general council of 30 members. It has its seat at Basse-Terre, the capital, and exercises jurisdiction over the islands of Guadeloupe, Marie Galante, Désirade, Les Saintes, and St. Martin. Grande-Terre possesses two harbors, those of Moule and Pointe-à-Pitre. The latter, at the S. entrance of the Rivière Salée, is one of the best in the Antilles, and is the residence of a United States consul. Guadeloupe was discovered by Columbus in 1493. The French took possession of it in 1635, and after having been repeatedly taken from and by them in the next century and a half, it was ultimately restored to them in 1816. Slavery was abolished in 1848.

**GUADIANA** (anc. *Anas*), a river of Spain, rising on the N. side of the Sierra Alcaraz, in La Mancha, and falling into the Atlantic between the Spanish town of Ayamonte and the Portuguese town of Castro Marim. It flows first N. W., and after several windings enters Estremadura, which it traverses in a westerly direction, passes Badajoz, and forms altogether 60 m. of the boundary between Spain and Portugal. In the Portuguese province of Alentejo it forms a cataract called the Salto del Lobo (wolf's leap), a narrow passage between the Sierra Abeloeira and the Sierra de Caldeirão. It is navigable above the Chanza. Length about 380 m.

**GUADIX**, an old city of Spain, in the province and 42 m. E. N. E. of the city of Granada, on the N. declivity of the Sierra Nevada; pop. about 11,000. It was once a place of considerable strength, and is still surrounded with walls, and is said to be the oldest bishopric in Spain. It has manufactories of silk, sail cloth, cutlery, and earthenware.

**GUAHAN**, Guam, or *San Juan*, the largest and southernmost of the Ladrone islands, in lat. 13° N., lon. 145° E.; pop. about 5,000. It is about 100 m. in circumference, and surrounded by coral reefs. The coasts are broken by several bays, one of which, called Calderon de Apra, is a commodious haven. The S. part of the island is of volcanic formation, and there is also a small volcano in the N., but the shores on this side are high and coralline. The interior is well watered, wooded, and fertile, rice, maize, cacao, sugar cane, indigo, cotton, and fruits growing in profusion. The domestic animals of Europe were imported long ago, but most of them have become wild. The primitive possessors of the island were long

since extirpated. The present inhabitants, descendants of Mexicans and Philippine islanders, are peaceable, and are skilful mechanics. The principal place is San Ignazio de Agana, a fortified village of bamboo huts, having a good harbor enclosed by coral reefs. The island was discovered by Magalhaens in 1521.

**GUAIAIACUM**, a name applied to both the wood and a resinous substance from the *guaiacum officinale*, of the natural order *zygophyllaceæ*. The tree grows in the West Indies and on the mainland opposite. The trunk is sometimes 5 ft. in circumference. The wood, commonly known as *lignum vitæ*, is remarkably heavy and hard, and is much used for the sheaves of tackle blocks, for nine-pin balls, and other purposes requiring strength and resistance to wear. It possesses medicinal properties, as does also the concrete juice or resin. Both are kept by druggists, the wood in the form of chips or shavings, and the resin in lumps or powder under the name of gum guaiacum.

*Guaiacum officinale*.

The wood contains about 26 per cent. of resin, and 0·8 of a bitter pungent extractive. The resin, which is the more active medicine, is obtained either by spontaneous exudations from incisions made into the tree, or by heating blocks of the wood, in which auger holes have been bored in the centre in the direction of the grain, and collecting the juice as it flows out through the holes; also by boiling the chips and sawdust of the wood in salt water, and skimming off the matter which rises to the surface. This is the form in which it is usually met with. More rarely it is found in rounded or oval masses, about the size of a walnut, called "guaiac in tears;" this is said to be produced by *G. sanctum*, another West Indian species, which is also found in southern Florida. The irregular-shaped pieces brought to the United States are of a dark olive color without and reddish brown within, diversified with various shades; they have a slight fragrant odor, and a pungent acrid taste after being held in the mouth a short time. The

pure substance is entirely soluble in alcohol, ether, alkaline solutions, and sulphuric acid. It is adulterated with common rosin, from which it may be distinguished by the solubility of the latter in turpentine. The powder and the tincture become green on exposure to light. The tincture affords blue, green, and brown precipitates with the mineral acids, and a blue color with oxidizing agents. If tincture of guaiacum is applied to the freshly cut surfaces of many vegetables, or added to infusions of the green plants, it gives a bright blue color, which is due to the presence of oxygen in the nascent form or of ozone, for the presence of which guaiacum is a useful test. The color is most marked at those portions of the plant where growth is taking place most rapidly. Similar reactions afforded by guaiacum with blood, pus and mucus, have been made available for physiological and medico-legal purposes. Guaiacum is administered in many complaints, especially chronic rheumatism. It promotes various secretions, especially those of the skin and kidneys, but diminishes excessive secretion of mucous surfaces. In large doses it purges. Febrile affections and irritated conditions of the gastro-intestinal membrane contraindicate its use. When a rheumatic diathesis underlies bronchitis, leucorrhœa, dysmenorrhœa, amenorrhœa, or syphilis, guaiacum often yields an unequivocal benefit. It is much less used now than formerly. It may be given in the form of decoction of the wood, tincture of the resin, or of the resin in substance. The dose of the latter is from 10 to 30 grs.; of the tincture, about a teaspoonful.

**GUAICURUS**, a nation of Brazilian Indians, in that portion of the region watered by the Paraguay between lat. 18° and 22° S. They are of medium height and strong, and their skin is of copper color. Their hair is long and straight. Formerly they tattooed their bodies. The only garment of the men was a sort of short drawers; on feast days they ornamented their heads with crowns of feathers, while in the under lips they inserted a cylindrical piece of wood about three inches long. The women are ill shaped and always painted. They accompany the men in all their excursions on horseback and in canoes, and the men aid them in cooking. Their chief occupations are spinning cotton, weaving, making utensils of earthenware, and manufacturing cords and mats. The riches of the Guaicurus consist in the number of their horses, which they mark just as they mark their women. They live mostly on venison, fish, and fruit, and hate agriculture. Their language is harmonious, though somewhat guttural. They count the years by the return of the fruit season. A few of these Indians were converted by the early missionaries, but the mass are still pagans. The population is distinguished into the classes of the nobles, warriors, and slaves.

**GUALEYGUAY**. 1. A river of the Argentine Republic, which rises in the mountains in the

centre of the province of Entre-Rios, flows S. and S. W., unites with the Pabon, and falls into the Paraná, after a course of about 150 m. It is navigable by schooners to the town of Gualeyguay, 40 m. from its mouth. **II.** A town on the left bank of the river, 120 m. N. by W. of Buenos Ayres; pop. about 8,000. It is in the midst of an extensive sheep and cattle district, is growing rapidly, and has an active trade in hides, wool, timber, and firewood.

**GUALEYGUAYCHÚ**, a city of the Argentine Republic, on the right bank of the Gualeyguaychú river, in the province of Entre-Rios, 120 m. N. of Buenos Ayres; pop. about 25,000 (in 1849, 7,000). The streets are wide, regular, and kept in good order, and the town is well built. In the surrounding country immense numbers of cattle and sheep are reared; there are many salting establishments in the vicinity, and there is a large trade in jerked beef, hides, wool, tallow, bone manure, and other animal products. Gualeyguaychú is the entrepot for all the export trade from the eastern portion of the province.

**GUAM.** See GUAHAN.

**GUAMANGA.** See AYACUCHO.

**GUAN**, a gallinaceous bird, of the family *cracidae* or curassows, and subfamily *penelopinae*; it includes the genera *ortalida*, *penelope*, and *oreophasis*, the first two South American, and the last peculiar to Central America. (For the family characters, see CURASSOW.) In the genus *penelope* (Merrem) the bill is shorter than the head, broad at the base, arched at the tip; wings short and rounded, with the fourth to the sixth quills the longest, and the first series arched and narrowed at the ends; tail long, very broad, and rounded at the end; tarsi rather

from 2 to 2½ ft. in length; the color is a shining reddish green, with rump and belly chestnut, neck and chest white spotted; naked temples violet, and the throat and feet red; the female is of a more reddish tint, with the crest, neck, and mantle bordered with white. Several other species are described, all inhabiting the central portion of South America. Though the guans have most of the habits of the curassows, they are far less gregarious; they are more noisy and restless, and have two broods in a year, about January and June; the nests are built in trees. They are mild and peaceable, easily domesticated, breeding in captivity. They are heavy fliers, but rapid runners, keeping their wings unfolded.—The paragua guans (*ortalida*, Merrem) have the head and throat covered with feathers, or with very slight bare spaces on the cheeks and throat; the bill is higher and more pheasant-like than in the *penelope*. The best known species (*O. katraea*, Bodd.) is about 20 in. long, bronzed-colored above, whitish beneath, and reddish on the head; they prefer woods near the seacoast, and are fond of cultivated fields; the voice is loud and disagreeable, resembling the utterance of their specific name; they are found only in the warm regions of South America.—A curious and handsome bird of this family is the *oreophasis Derbyanus* (Gray), from Guatemala. The base of the bill is covered with velvety black down; the space above the eye is naked, and the forehead is surmounted by a broad, rounded, truncated red knob; there is a small bare space on the throat. The general color above is greenish black; below whitish, with longitudinal blackish dashes; white band on the middle of the long and rounded tail; bill, legs, and bare spaces red.

**GUANABACOA**, a town of Cuba, on a bay of the same name, 2 m. E. by S. of Havana; pop. about 7,000. The streets are wide and regular, and the houses remarkably well built, many of them being very handsome. It has a church, two convents, a theatre, philharmonic society, schools and academies for both sexes, and several hospitals. It is rendered especially attractive by its sea baths, which are frequented by the wealthy Havanese. Many Havana merchants reside here. It communicates with Havana by rail.

**GUANACACHE**, a lake of the Argentine Republic, in the province of San Juan, lat. 31° 50' S., lon. 68° 40' W. Its length is about 40 m., and mean breadth 14 m.; it is fed by the Mendoza, San Juan, and other rivers, and sends its waters through the Cruces and Lake Silverio to the large lake El Bebedero on the confines of the provinces of San Luis and Mendoza.

**GUANACASTE**, a province of Central America, lying between Lake Nicaragua and the bay of Nicoya, and comprising a broken country, thinly populated, and only adapted for grazing. During the dominance of the Spanish crown it was under the political and ecclesiastical juris-

Crested Guan (*Penelope cristata*).

slender, as long as the middle toe; hind toe long and on the same plane with the others; claws short and curved; the sides of the head and front of the throat naked and wattled, the latter capable of inflation. The crested guan (*P. cristata*, Linn.) is the largest, measuring

diction of Nicaragua; but after the independence, and the establishment of the republic of Central America, it was set off by the federal congress to the state of Costa Rica. The measure was declared to be temporary, and was against the wishes of its inhabitants. On the dissolution of the federation, Costa Rica asserted jurisdiction over it, on the strength of the enactment of congress; the question led to bitter discussions, until by a treaty in 1858 the greater part of the district was conceded to Costa Rica. Nicaragua still urges her claim to the province. In 1873 telegraphic communication was established between Libertad, the capital, and San José, the capital of Costa Rica.

#### GUANACO. See LLAMA.

**GUANAJUATO.** I. A central state of Mexico, lying between lat. 20° and 22° N., and lon. 100° and 102° W., and bounded N. by San Luis Potosí, E. by Querétaro, S. by Michoacan, and W. by Jalisco; area, 11,130 sq. m.; pop. in 1869, 874,073, about 200,000 of whom are whites of Spanish descent, 300,000 pure-blooded Indians, many of whom speak only their own languages, and the remainder mestizos. The state is divided into five departments: Guanajuato, Leon, Celaya, Allende, and Sierra Gorda. The principal towns are Guanajuato, Celaya, San Miguel de Allende, Salvatierra, Salamanca, and Silao. The surface of the country, almost the whole of which is comprised within the plateau of Anahuac, at a mean height of 6,000 ft. above the sea, is extremely irregular. It is traversed

by two mountain chains from S. E. to N. W.; that to the north is the Sierra Gorda, the other the Sierra de Guanajuato. In the latter are the three peaks of Los Llanitos, upward of 9,000 ft. high, El Gigante, and El Cubilete. There are other cordilleras to the south, between which and the Sierra de Guanajuato lie picturesque and fertile valleys, watered by numerous torrents, and comprehended under the general designation of El Bajío. The three principal rivers are the Río de Lerma and its tributaries, the Laja and the Turbio. The only lake of note is the Yuriria, not far from the capital, 12 m. long and  $4\frac{1}{2}$  broad; its waters, which are perfectly fresh, abound in *bagres*, a small fish much esteemed. Most of the mountains are porphyritic, but the Cerro del Cubilete is mostly basaltic. The mines of Guanajuato are by far the richest in the republic. The most extensive silver mine was that of Valenciana, which for

40 years yielded an annual profit of \$3,000,000; in 1803 its depth was 1,800 ft.; it was worked by 3,100 Indians and mestizos. Lead, tin, copper, iron, cobalt, sulphur, salts, crystals, marble, &c., are found in many parts of the state. There are numerous hot and sulphur springs, well known and much frequented by invalids. The climate in the department of Guanajuato is generally mild and salubrious, while in the district of La Luz and in the elevated regions of the Sierra de Guanajuato it is quite cold. Some years little or no rain falls, and the crops fail. The soil of Guanajuato is one of the most fertile in Mexico, and large crops of wheat, barley, maize, potatoes, and several varieties of beans are obtained. Chilli, the fruit of the *capsicum annuum*, is one of the staple products; the magney (*agave Americana*) is plentiful; the sugar cane grows well in some parts; the olive flourishes, as do most of the European fruits and leguminous plants; and the forests produce an abundance of building

Cathedral of Guanajuato.

timber. The chief industry is mining; but agriculture is the favorite occupation of the Indians. There are cotton-spinning factories in Salamanca, which is also celebrated for its excellent earthenware; cotton fabrics are made in Salvatierra; woollen stuffs in Celaya; and tanneries exist in all the large towns. The staple articles of export are the precious metals, spices, medicinal plants, and hides. II. A city, capital of the state, situated in a deep valley 6,836 ft. above the sea, 160 m. N. W. of Mexico; lat. 21° 1' N., lon. 101° W.; pop. about 63,000. Such is the unevenness of the site that in many streets the houses appear to be built in amphitheatre, and often the door of one dwelling is almost on a level with the roof of the next. Most of the streets are too narrow for wheeled vehicles, and all are extremely irregular. On the east rises a mountain torrent which passes through some of

the streets, and causes much damage during floods. Guanajuato has many handsome buildings, private and public; among the latter are the *alhóndiga de granaditas* (now used as a public granary, but memorable as the scene of important events during the war of independence), the parish and several other churches, monasteries and convents, and the mint. There are also a college, several public and a few private schools, a theatre, a hospital, and a charitable institution.—Guanajuato was founded in 1554, and was made a city in 1741.

**GUANARE**, a city of Venezuela, in the state of Barinas, 215 m. S. W. of Caracas; pop. about 12,000. It is situated in a picturesque valley, has straight wide streets, well built houses, and a few substantial public buildings, one of which is its church, much resorted to by pilgrims. There is a college, and dependent upon it a few schools. Cattle are the chief source of wealth. The principal articles of export are cacao, coffee, indigo, sugar, and tobacco. Guanare was founded in 1593 by Juan Fernandez de Leon, or according to some in 1609. A river of the same name (sometimes called the Guanarito), a tributary of the Orinoco, passing within 3 m. of the city, considerably facilitates exportation.

**GUANCHES**, the aborigines of the Canary islands, extinct since the end of the 16th century. They are said to have been gigantic in stature, well proportioned, of an olive complexion, with long straight hair, and simple and mild in character. They believed in an invisible creator of the universe, an evil spirit, a future state, and a place of torment for the bad, which they supposed was in the volcano of Teneriffe. They preserved the bodies of their dead and deposited them in catacombs, which are now visited among the curiosities of the islands. They had solemn marriage rites, in preparation for which the brides were fattened on milk. Not more than 150 words of their language are known, and these have an analogy with certain Berber dialects. Their origin is disputed. Some regard them as Libyans who fled to these islands on the conquest of Barbary by the Arabs, and this opinion is supported by the similarity of several customs of the Libyans and Guanches. Humboldt supposes them to have belonged to the races of the old continent, perhaps to the Caucasian, and not, like the rest of the Atlantes, to the nations of the western world.

**GUANCABELICA**. See **HUANCAVELICA**.

**GUANO**, a town of Ecuador, in the province of Chimborazo, about 100 m. S. W. of Quito; pop. about 9,000. It contains many fine houses, a handsome church, and manufactories of woollen stuffs, carpets, blankets, sulphuric acid, &c. Cinchona bark is exported.

**GUANO** (Sp. *guano* or *huano*, Peruvian *huanu*, dung), the excrement of sea fowl, intermixed with their decomposed bodies and eggs, and the remains of seals, found accumulated principally upon the islands of the Pacific and coasts of South America and Africa. The three small

islands called the Chincha islands, off the south coast of Peru, and the Lobos islands off the north coast, were covered with it. It was known to the ancient Peruvians as a valuable manure, and the immense deposits of it were an especial object of care to the incas. Acosta (quoted by Prescott) states that during the breeding season no one was allowed under pain of death to set foot on the islands on which it was produced, and to kill the birds at any time was a like offence. The Spanish conquerors called the islands the Sierra Nevada, or snowy mountains, from the hills covered with white saline incrustation. Humboldt first drew attention in Europe to the substance in 1804. He described the deposits as covering the granitic rocks of the Chincha islands to the depth of 50 or 60 ft., and yet the accumulation of the preceding 300 years had formed only a few lines of this thickness. He procured analyses to be made of the substance by Fourcroy, Vauquelin, and Klaproth, by which it was found to be composed of phosphate of ammonia and lime, with urate and oxalate of ammonia, water, organic matters not determined, and some sand. Sir Humphry Davy alluded to it about 1810 as likely to prove valuable to European farmers; and in that year a trial was made of it at St. Helena by Gen. Beatson. But none was brought to Europe for trial till 1840, when 20 casks were imported into Liverpool by Mr. Myers. The next year the shipments amounted to several cargoes. The exclusive right of digging and shipping guano for the term of nine years was sold at this time by the Peruvian and Bolivian governments for the sum of \$40,000; but the contract was soon after repudiated by the former, as the increasing demand for the article developed the immense value of the deposits. The monopoly was soon after revived, however, the Peruvian government confining the exportation and sale to a single house in London and another in New York. Upon the Chincha islands it was estimated that there were about 40,000,000 tons, the largest one having no less than 17,000,000 tons. The Lobos islands also contained enormous deposits, and many smaller islands were covered with it. Upon the principal Chincha island the deposit is said to attain a thickness of 160 ft. The exports from these localities rapidly increased, so that guano became an important article of commerce, and vessels returning from the Pacific to England or the United States now found a profitable return cargo at the Chincha islands, instead of going as they had previously done to China and the East Indies in search of one. The revenue to the Peruvian government from this trade exceeded that from all other sources; and its agents reaped enormous profits from their authorized commissions upon the shipments. The demand led to explorations in other parts of the world, and other deposits were found, but nearly all inferior in quality to those collected upon the rainless islands off the coast of Peru. Upon

these the ingredients have remained little changed in the dry atmosphere and under the tropical sun. The uric acid and ammonia, both products particularly subject to ferment and decompose in the presence of moisture, remain unaltered, except as they become dry and are locked up in the coarse brown powder produced from these and the other ingredients of the excrement. So the nitrate of soda and common salt, both deliquescent in a moist atmosphere, are found as a dry deposit among the parched sands of the desert of Atacama in the same rainless district. In localities subject to rains these valuable nitrogenous compounds disappear, and the value of the guano consists principally in the next useful ingredients, the phosphates, which remain. The greater portion of the guano product of Peru is sent to England. The entire imports into Great Britain amounted in 1870 to 280,311 tons, valued at £3,476,680; in 1871, 178,808 tons, valued at £1,986,989; and in 1872, 118,704 tons, valued at £1,201,042. Of the imports in 1872, 74,401 tons, valued at £875,882, came from Peru; 17,475 tons, worth £113,073, from the islands in the Pacific; and 14,068 tons, worth £108,150, from Bolivia. During the year ending June 30, 1872, there was imported into the United States 14,309 tons of guano, valued at \$423,323, of which 11,654 tons, worth \$385,063, were from Peru, and 1,820 tons, worth \$24,473, from the British West Indies. Besides this amount, 4,209 tons, valued at \$60,865, were from the islands, rocks, and keys belonging to the United States.—The composition of guano is exceedingly complex. The following minute analyses of South American samples

were communicated by J. Denham Smith to the chemical society, and published in vol. ii. of their "Memoirs." Nos. 1 and 2 were in the state of powder; the others were of the concrete variety:

For commercial purposes it is of no importance to enumerate all the compounds. The approximate value of samples can be arrived at in the following manner: Multiply the values named below by the per cent. found of each ingredient; the sum obtained will represent the value of 100 tons of the guano. Thus for the nitrogen found the rate per cent. is \$370, or if, instead of this being separated, the ammonia is estimated, the rate is \$300; for phosphate of lime the additional amount is \$40; soluble phosphate of lime, \$120; organic matter, \$5; alkaline salts, \$5; sulphate of lime, \$5. Example of sample of first-class Peruvian guano:

	Per cent.	
Moisture.....	15.10	
Organic matter.....	51.27 ×	\$5 = \$256 35
Silica.....	2.20	
Phosphate of lime.....	22.13 ×	40 = 885 20
Phosphoric acid.....	3.23	
Alkaline salts.....	6.07 ×	5 = 30 35
100.00		
Soluble phosphate of lime, equivalent to the phosphoric acid above.....	7.00 × 120 =	840 00
Ammonia derivable from the organic matter above.....	16.42 × 300 =	4,926 00
Value of 100 tons.....		\$6,987 90

The following three analyses of Jarvis island and one of Baker's island guano are by Prof. John C. Draper of New York:

CONSTITUENTS.	Jarvis Island.		CONSTITUENTS.	Jarvis Island.	Baker's Island.
Water .....	20·00	17·50	Water .....	7·50	4·50
Org. matter and ammon' l salts	3·00	4·00	Organic matter	4·00	11·00

Sulph. of lime.	52·00	44·50	Sulph. of lime..	5·00	81·00
Alkaline salts..	4·00	4·00	Phos. of lime..	81·00	76·80
			Carbs. & silica	....	1·50
Total.....	100·00	100·00		100·00	100·00

Analyses and calculations like those given ought to be made in entering upon all large purchases of guano, as well on account of the great natural differences in the qualities of the various kinds, even from the same locality, as of the gross adulterations which are largely and most ingeniously practised; substances of no value as fertilizers being intermixed with the genuine article, so as to very materially reduce its value. Full half the guano sold in England is said to be thus deteriorated. The analyses, moreover, are of importance, as they indicate the most advantageous methods of applying the guanos, and for what crops and what soils they are best adapted. But for the knowledge of their composition thus acquired, the best Peruvian guano, rich in ammonia, might be extravagantly employed upon soils that would be almost equally benefited by the cheaper qualities, of which the phosphates are the chief fertilizing ingredients. Upon light soils especially, the ammoniacal guano may be used to waste, owing to the little obstruction they present to the escape of its volatile and very soluble portions; the full benefit of these will be secured only in the strongest soils, or in composts prepared with the view of their absorption and retention. In such mixtures guano is used most advantageously. Of itself alone it may furnish all the ingredients required by the plants; but its activity and evanescence need to be checked, and on account of its caustic quality care should be taken that it be not brought in direct contact with the seed. The quantity of best guano that should be employed to the acre is generally rated at from 3 to 5 cwt.; and it should be applied in wet weather, when the rains diffuse it equally through the soil. The Peruvians, it is said, irrigate immediately after applying it. They use it only for Indian corn and potatoes, burying about half a handful near each root when the plants are perhaps half grown, and adding some water "to fix the guano." In this country it is found to be an excellent top dressing for grass and young corn, and is a most efficient manure for all the root crops.—The search for new localities of guano led to the discovery in 1855 of animal deposits of the same original nature upon the groups of islands lying off the coast of Guiana and Venezuela. Immense flocks of sea fowl frequent these islands for the purpose of laying their eggs. But being in the region of the tropical rains, the deposits of excrement and other organic matters are subject to chemical

changes, from which result singular products, very different from those of the earthy guano of the dry islands of the Pacific. The principal groups which furnish these products are Los Monges (Monks' island), El Roque, and Centinella. Some of the islands are low, and strewn with sand, which is made up of comminuted coral, madrepore, and shells, in which the birds lay their eggs. Others rise in peaks to the height of 800 ft., and upon these are stratified rocky layers of metamorphic guano, sometimes covered with the deposits still in process of accumulation. Several qualities of guano are recognized, one of which is arenaceous, in grains as coarse as mustard seed, light yellowish brown or nearly white when dried, exhaling an odor not ammoniacal, but like that of freshly dug earth. Its average composition is thus stated by Dr. A. A. Hayes: moisture, after drying, 4·40; organic matter, 6·40; bone phosphate of lime, 46·60; carbonate of lime, 39·80; phosphate of magnesia, 1·20; sulphate of lime, 0·80; sand, 0·21; traces of chloride and sulphate of soda; total, 99·41. The ammonia or nitrogen in the organic matters does not exceed 2 per cent. of the whole. Another variety is in aggregated grains, the first step in the change of the material into rock. It differs in composition from the preceding principally by loss of carbonate of lime and increased proportion of bone phosphate. A third variety is a solid rock, which forms a crust sometimes 2 ft. thick over the lower portions of the deposit, and is the product of the change that has taken place upon the surface of the mass. Its composition is somewhat variable at different localities; but it is everywhere distinguished by the disappearance of carbonate of lime and large increase in the proportion of phosphate and sulphate of lime. The carbonate of lime has been decomposed by the acids generated in the fermentation induced by the moisture at the prevailing elevated temperature, and with other soluble matters has been removed by the rains. The passage of the gaseous exhalations through the mass, gradually thickening as its aqueous portion evaporates and the salts gather at the surface, renders its structure porous and cellular, and so much like that of some trachytic rocks that the substance has been mistaken for one of igneous origin, or at least metamorphosed by heat. The granular structure has given place to a compact, close texture, and a mineral appearance and hardness closely approaching that of feldspar; and in some specimens are observed angular fragments and grains hardly to be distinguished by the eye from epidote. The external surface has an uneven weathered appearance like that of trap rock, and is of a lighter color than the body of the rock within. Various analyses have been made of this substance by different chemists, and it is found to consist principally of phosphoric acid and lime, the former generally ranging from 37 to 46 per cent., and the latter from 39 to 41 per cent., of which a small

portion is combined with sulphuric acid to form sulphate of lime, the proportion of this sometimes exceeding 8 per cent., and the crystals being visible in the cells of the mineral. Water and organic matters sometimes exceed 10 per cent. In the body of the rock the phosphoric acid is found combined with two atoms of base and one of water, in the form of common phosphate of lime; while the external part is a combination of an atom of acid with three of lime, forming the so-called tri-phosphate of lime. The acid is also sometimes combined in small proportion with iron, alumina, and magnesia. Soda is present in some samples to the amount of 2 or 3 per cent. Much of the guano rock closely resembles in appearance the phosphate of lime rocks of the older crystalline formations; and it affords a remarkable instance of the conversion of modern collections of organic substances into what appears to be an ancient rock. Though traced directly into the mass of these substances with which it is associated, and the derivation of which is obviously from the digested bones of fishes and other food of birds, from comminuted shells, and the remains of the birds themselves and of their eggs, all vestiges of animal life have as completely disappeared in the hard strata as they have from the true metamorphic rocks, the changes in which we have been accustomed to ascribe to intense heat produced under the pressure of superincumbent mountains of rock, and exerted through long and indefinite periods.

**GUAPEY.** See RIO GRANDE.

**GUARANA**, a paste formed chiefly from seeds of *Paullinia sorbilis*, and perhaps *P. cupana*, climbing shrubs of the order *sapindaceae*, growing in Brazil and on the banks of the Orinoco. The paste is dried into rough, hard, reddish brown masses, which may be reduced to powder. It is habitually used by the Brazilian Indians as a part of their diet, either mixed with other articles or as a drink. It is said to contain more than 5 per cent. of a crystallizable principle identical with caffeine, and has in addition tannic acid and two or three volatile oils. It has long been used in Brazil as a medicine, especially in the treatment of diseases of the bowels; but although known in Europe for a number of years, it has only recently received much attention. Its action upon the system in a state of health is apparently negative, as it affects neither pulse nor temperature. An increased capacity for mental labor, moderate wakefulness, and an influence upon the nervous system, similar to that produced by tea and coffee, have been observed. It evidently acts somewhat like a tonic; but more accurate observations than any we now possess are requisite in order to determine its physiological action upon the system. It has recently been used both in this country and Europe with advantage in the treatment of headaches, especially those of a nervous character. It renders the greatest service in such cases when it is administered near the commence-

ment of an attack, and repeated at short intervals. It is best given in milk, and should be repeated if necessary at intervals of half an hour, three or four times, in doses of from ten grains to half a drachm. In other nervous affections it has been tried, especially in nervous derangement of the stomach, but in these it has not been found useful. Its action closely resembles that of tea and coffee. A fluid extract has also been made. Its administration is contra-indicated by an inflammatory condition of the system.

**GUARANÍS.** See TUPÍ-GUARANÍS.

**GUARANTY.** This word is derived from the old English word warrant. The Latin and the Norman French languages, not having the letter *w*, in spelling this word and many others used the letter *g* instead of *w*, as in the name Wilhelm or William, which is in Latin Guilielmus, and in French Guillaume. Thus the barbarous word *guarantiso* came into use in law proceedings, although the even more barbarous word *warrantiso* was also used. Gradually the words became distinguished in their meaning; and at present it is found very convenient to use the Latin form guaranty in one sense, and warranty in a different although an analogous meaning. A guaranty is a promise that some other party (who is called the principal) shall pay a debt, or discharge some duty, or perform some act; and to answer for the consequences if the principal fails to do what is thus promised. It is an extremely common business transaction; and we shall endeavor to give the principal rules by which it is governed.—Every indorser of negotiable paper is in fact a guarantor; but in such a peculiar way, that the law attaches to him duties on the one hand, and on the other gives him rights, not known to common guarantors. (See NEGOTIABLE PAPER, and PROMISSORY NOTE.) Every surety also is a guarantor, and the law for guarantors and for sureties is in many respects similar, but in other respects different. (See SURETY.) In the first place, a guaranty is not in general negotiable; by which is meant that it cannot be transferred in such a way as to give the transferee the right of suing upon it in his name, or, if this be permitted, of suing with all the rights and advantages of an original holder. In the next place, although it is a promise only to pay the debt of another, the guarantor may be held, although the promise of that other was voidable by him who made it, and could not be enforced at law; as if it were the promise of an infant, and not for necessities, or of a married woman. In fact, guaranties are very often taken for the very reason that the debt or promise guaranteed is one which has no value by itself. But generally, the liability of the guarantor is measured and determined by that of the principal, or the party whose debt or promise is guaranteed. No especial words or phrases or form of instrument is necessary to constitute a guaranty. The intention must be manifest, and the words must be such as may

be construed into an expression of that intention; and this will be sufficient. The contract of guaranty is one which is construed, if not severely, at least exactly. Thus if A guaranties the notes of B, he is not bound for notes which B signs jointly with C; and if B changes his business or the nature of his debts, so as to throw upon A a liability distinctly different from that which it was his intention to assume, A is thereby discharged from his guaranty.—The guarantee (or party guaranteed) must preserve all the securities he has of the principal debtor unimpaired, because if the guarantor pays the debt, he is entitled to all these securities; and a court having equity powers will, upon cause shown, compel the guarantee to do what he can to turn these securities to account for the benefit of the guarantor, if the guarantee alone can do it, or can do it to the most advantage, before it will permit him to call upon the guarantor. Indeed, it may be regarded as a fundamental proposition of the law of guaranty, that the guarantee shall act with entire fairness toward the guarantor, and shall do all that can properly be done to lessen his burden. Therefore if the creditor, being guaranteed, agree with the principal to reduce his debt in any certain proportion, he shall be understood to make the agreement for the guarantor's benefit as much as for his own, and therefore the guaranty shall be reduced in the same proportion. Still, however, it seems to be generally held that the guarantor's right is confined to the securities for the debt, and does not extend to the debt itself; if therefore a guarantor pays a debt, it is said that he has no right to demand from the creditor a transfer of the debt itself, or of the note by which the debt was evidenced, for the reason that this very debt has been already paid or discharged by himself as guarantor. But he may demand, with the securities, the note itself, or a transfer of the debt, if this be necessary to make the securities available; and it would be difficult to resist his right, we should say, to be subrogated to the creditor's claim, so far as he could make that available to himself. But the law on this point can hardly be considered as distinctly settled.—The promise to pay the debt of another, like every other promise known to the law, must rest upon a good consideration, or it cannot be enforced by legal process. The law on this subject is a little nice in respect to guaranties; for while it demands inexorably that there should be a consideration, it sometimes declares that if the promise which is guaranteed rests upon a good consideration, this same consideration shall be sufficient to sustain the promise of guaranty; but if the guaranty is given subsequently, after the consideration for the original promise is executed and passed, so that it can have no force or application whatever to the new and distinct promise of guaranty, the latter will require a new and distinct consideration for its support. But to make this consideration suf-

ficient, it is not necessary that anything shall pass directly from him who receives the guaranty to him who gives it; for if the party for whom it is given, or the party by whom it is given, receive any benefit, or the party to whom it is given suffer any loss or injury, from or by reason of the promise of guaranty, it is a good consideration. The guarantee must conduct himself in all respects with entire good faith, and if there be any taint or fraud about the consideration (as, for example, if a guaranty is given for a certain amount of goods sold, and the seller has made an arrangement with the buyer whose debt is guaranteed, by which arrangement the buyer is to pay him more than the true price, the difference going toward an old debt due from the buyer to the seller), this is a fraud upon the guarantor, and he is discharged not only as to this unfair excess, but as to his whole promise of guaranty.—A guaranty, being a promise to pay the debt of another, is precisely within the clause of the statute of frauds which requires that such a promise be in writing and signed by the guarantor. It often happens, however, that a guaranty, or a contract which has all the appearance of a guaranty, and which is not in writing, is still enforced by the courts. This occurs when they can hold the promise to be an original promise, and not a collateral promise. For an original promise is a promise to pay one's own debt; while a collateral promise is a promise to pay a debt which is primarily the debt of another. This is a very nice and difficult question, and has been very variously decided. The disposition of the courts so to construe and apply the statute of frauds as that it shall not be an instrument of fraud, has led them to some strange decisions. Comparing the cases, and drawing from them the true principle which must govern the question, we should say the rule must be this: If one who promises to pay the debt of another receives an independent consideration for his promise, and thereby enjoys a benefit or advantage which is entirely his own, and which he would not have enjoyed but for the transaction, then the promise is to be regarded as his promise to pay his own debt, and therefore needs not to be in writing. As an illustration of this question, which is frequently recurring and always difficult, we should say that if the creditor had attached the property of the original debtor, and the alleged guarantor had requested that the attachment might be discharged and agreed to pay the debt if it were, and the attachment was then discharged and the property set free, this would not be enough to make it the guarantor's promise for his own benefit, or his original promise, and therefore it could not be enforced, unless it was in writing. But if the alleged guarantor had requested not only that the attachment should be discharged, but that the property should be delivered over to him for his own advantage, this new element would make his promise one for his own benefit, or, in the language of the law,

an original and not a collateral promise, and therefore it needs not to be in writing. So, if A delivers goods to B, at the request of C, who is to pay for them, and who may be considered as the buyer of them, C, when he promises to pay for them, promises to pay his own debt, and therefore the promise may be in spoken words only. But if A sells goods to B, on C's promise to pay for them if B does not, then A's promise is only collateral to B's, and it must be in writing. The question therefore is, were the goods sold to C for the benefit of B, or were they sold to B on C's guaranty? On this question the seller's entry in his books is sometimes very important evidence. If he charges C with them primarily, this may not go far to bind C, because he may have charged them so for the very purpose of holding C. But if he charges them simply to B, it will be very difficult for him to prove afterward that he considered himself as selling them to C, and not to B on C's guaranty. But still he might show that even this entry was made by mistake, and did not represent the truth.—The contract of guaranty, like every legal contract, requires two parties, who agree to the same thing. It follows therefore that a guaranty, or a promise to pay the debt of another, is not valid until it is accepted; and this is true, whatever be the consideration, and whether it be in writing or otherwise. But this acceptance need not be direct and unequivocal; indeed, it need not be in any words whatever; it may be implied from circumstances. Thus, if A goes with B to C, and says to C, "If you will sell B the goods he wishes, I will see that he pays you the price," and C, without reply to A, turns to B and sells and delivers him the goods, there would be no question in this case as to whether C accepted and acted upon the guaranty of A. It is under a different class of circumstances that this question generally arises. Thus, if the guaranty were by letter, and referred to subsequent operations, the question would then arise whether there was a sufficient acceptance of it. Some courts have asserted that the guarantor had a perfect right to know whether his offer was accepted, and whether he stood bound as guarantor; and some have gone so far as to hold that the guarantor was entitled to know at once, not only that his guaranty was acted upon, and the amount, but all the terms of the sale which it could be desirable for him to know, that he might arrange accordingly. On the other hand, courts of the highest authority have held, that where an offer of guaranty is absolute, and does not expressly or by distinct intimation call for any acceptance or any special information, the party making the offer might suppose it to be accepted and act on that supposition; and the party receiving the offer may act under it and within the terms of it, and hold the guarantor without giving him any notice of his acceptance. It has already been said that the party receiving the guaranty must conduct himself

with good faith and proper care toward the guarantor; and one effect of this principle is, that if any material change is made in the extent or the terms or character of the liability of the principal, this discharges the guarantor. Nor will a guarantor be held in such case by the party guarantied showing that the change was in no way injurious to the guarantor; because he has a right to judge for himself as to the circumstances under which he is content to be liable, and he may stand upon the precise terms of his contract. The guarantor may, however, assent to such a change, and then he will be held. Thus, if a new note be given for an old one, this discharges the guarantor on the old note; and it has been held that if a guarantor thus discharged, in ignorance that his liability has thus terminated, makes a new acknowledgment of this liability, he cannot be held thereon. So, a guaranty to a partnership is discharged by a change in the partnership, although no change in the firm or style of it be made; and this has been held where the guaranty was given "for advances made by them, or by either of them." The reason given is, that the guarantor may have trusted to the skill or care of the members of the firm as they stood when he gave his guaranty; and the change of a single member may be important in this respect. It should be stated, however, that the guaranty itself may provide expressly for all these changes, and will not, of course, be affected by any which it anticipates.—Whether a guaranty be a continuing guaranty, or be intended to cover one single transaction only, is sometimes a difficult question. In general, however, a guarantor who intends to limit his liability to a single transaction should so express it; but if it can be gathered from the terms of the guaranty that it was intended and should have been understood to apply to more than one transaction, it will be so held. The limit may be one of time, as to be liable for any amount of goods sold before a certain day; or one of amount, as for any goods up to a certain sum.—That a guarantor is entitled to a reasonable protection we have already seen, but it has been much disputed whether, on this ground, he may insist that the party guarantied shall proceed forthwith against the debtor. It would seem to be very unjust to the guarantor to permit a creditor to let his debt lie without taking any steps to secure it, because he knows that the guarantor is perfectly responsible, and he chooses to indulge some feeling of personal kindness to the debtor. This question has frequently come before the courts, especially in New York; and it must be admitted that the law is not quite certain. We think, however, that this rule may be drawn from the best authority, and sustained by strong reasons, viz.: that the guarantor is not discharged by mere delay of the creditor in calling on the debtor; but if after a request from the guarantor that he should proceed (especially if the request be accompanied by an offer to pay the costs of

proceeding), the creditor delay the demand and all proceedings so long and so stubbornly as to indicate great negligence if not fraud, and the guarantor can show that by such delay he has lost the means of indemnifying himself, the guarantor is now discharged, at least to the extent of the injury which he can show that he thus received. Nor is a creditor prohibited from giving to his debtor all indulgence whatever. He certainly may favor him in some respects without discharging the guarantor. After some fluctuation the law seems to have settled down upon the following rule: Mere forbearance of the debt, without fraud, does not discharge the guarantor; nor does an agreement to forbear, provided this is not so binding on the creditor as to prevent his suing the debtor at any time. That is, the creditor must retain the power of putting the debt in suit at any time; but if he retain this power, any forbearance consistent therewith does not discharge the guarantor. The reason is, that the guarantor has the right of paying the debt at any time after it is due, and so acquiring the right of suing it at once; and if the creditor destroys this right by putting the debt in such a condition that it cannot be sued at once, he deprives the guarantor of a valuable right, and so loses his hold upon him. Reasonable notice should also be given to the guarantor of the failure of the debtor, so that he may have all proper opportunity of obtaining indemnity. But what this reasonable notice should be is not quite settled. There is no time fixed, as in the case of indorsed paper, within which the notice of non-payment must be given; and perhaps the rule may be stated that no mere delay of notice would discharge the guarantor, unless he can show that he has suffered injury by such delay. But if he can show that if he had received this notice within a day or two from the time when the debt was unpaid, he might then have secured himself, and has now lost the opportunity, even that delay might suffice to discharge him.—Guaranties are sometimes given by one expressly in an official capacity as trustee, church warden, executor, assignee, and the like. But the guarantor is still held personally on this guaranty, unless, 1, he holds that office, and 2, has a right by virtue of the office to give the guaranty in his official capacity.—Every guaranty may, in general, be revoked at the pleasure of the guarantor, by giving due notice to the party guaranteed, unless, 1, the guaranty is given upon some continuing consideration which is not yet exhausted, and cannot be restored or rescinded; or, 2, upon some specific transaction, which is not yet wholly completed; or, 3, the guaranty is against the misconduct of some servant or officer, whom the guarantee cannot at once dismiss, or secure himself against by other means, if the guaranty be rescinded.

**GUARATINGUETA**, a town of Brazil, in the province of São Paulo, on the right bank of the Rio Parahyba, 120 m. W. of Rio de Ja-

neiro; pop. about 7,600. The streets are regular, but narrow, and the houses built of adobe. It has a church and three chapels; one of the latter, outside the town, is visited by numbers of pilgrims. The surrounding country is fertile, and sugar, coffee, and tobacco are cultivated, and, with fat cattle and swine, are sent in considerable quantities to Rio de Janeiro and to São Paulo.

**GUARD, National**, a system of militia instituted in France in 1789. The court had concentrated at the gates of the capital an army of 30,000 regular troops. To counteract this demonstration, the citizens demanded arms, and on July 13 a municipal council decreed the formation of a militia of 60 battalions numbering 48,000 men. White, the color of the royal standard, was united with the blue and red colors of the city of Paris to form the color of this revolutionary force, afterward so famous as the tricolor. The other cities of France promptly followed the example, and the institution took the name of national guard. In 1795 the national guard of Paris, to the number of 30,000, rose in arms against the convention, Oct. 5, and attacked the Tuileries, but were repulsed and defeated by 6,000 regular troops commanded by Napoleon Bonaparte. The national guard was now placed under the authority of the commander-in-chief of the regular army. During the revolution of July, 1830, the national guard was revived at Paris, and on July 30 Lafayette, who 40 years before had commanded the first national guard, was again made commander-in-chief. After the revolution of 1848 the national guard was largely increased, and by a law of June 26, 1851, it was organized throughout France, and made to include all citizens above the age of 20, except regular soldiers and persons employed in the service of the government. After the *coup d'état* of Dec. 2, 1851, it was dissolved, and re-established by a decree dated Jan. 11, 1852, on a new and much restricted plan, reducing it to the condition of a mere armed police for the repression of tumults. During the Franco-German war the national guard was reorganized. After the evacuation of Paris by the Germans and the ratification of peace by the national assembly, in the early part of 1871, the national guards still remained under arms. They refused to obey the orders of the government to disarm and disband, but seized a number of guns, and occupied the batteries of Montmartre and the quarters of Belleville and Villette. After the overthrow of the commune, the national assembly voted the dissolution of the national guard throughout France.

**GUARDIAN**, one who guards, or has the care and charge of another. Guardians in law are of many kinds. There are guardians of minor children, and of those incapacitated otherwise than by age from taking care of themselves. Guardians of infants (minors) were, at common law: 1. Guardians by nature. In exact and technical construction, by this term is meant

only that guardianship which belonged to the ancestor, in respect to the heir apparent. It extended only to the care of the person, and did not include the care of the property. 2. Guardians by nurture. This guardianship also extended only to the person and not to the estate; and it terminated when the ward was 14 years of age, whereas guardianship by nature continued until the ward was 21. It was given to the father, and if no father, to the mother. 3. Guardians in socage, limited to cases where the minor had lands by descent; and this guardianship extended over these lands and the person also, until the ward was 14 years of age. It fell by common law to the next of blood to whom the inheritance could not descend, and therefore this kind of guardianship could hardly have existed in the United States. 4. Guardians by statute; and 5, guardians by will, or testamentary guardians. These last two are almost the only ones known practically in this country (by statutes following that of 12 Charles II.), whereby a father has power to appoint by will a guardian for his minor children; and if such appointment be not made, or fails, the court of probate, or some other court exercising similar powers, makes the appointment. The statutes of different states make somewhat different provisions as to the persons to be appointed (usually the next of kin of proper age), the degree and way in which the minor is to be consulted, the bonds to be given, and the power and the duty of the guardian.—All guardianship is a personal trust, and is therefore not transferable by assignment, devise, or inheritance. Whether it expires by the marriage of a female ward who is still a minor is not certain, but, we think, probable. It seems that as to a male ward marrying, the distinction has been taken that it terminates the guardianship as to his person, but not as to his estate. The law can hardly be said to be settled in the United States generally as to the effect of the marriage of the ward. The marriage of a female guardian terminates her authority in some states by statute, and in others, generally at least, by practice. A married woman cannot be appointed guardian without the consent of her husband; but with that consent she may be.—The guardian has very full power over the personal estate of the ward, but very little over the real estate, any further than relates to the rents, issues, and profits, and to necessary law proceedings. He cannot dispose of the real estate generally, without an order from a court having jurisdiction, and can lease it only for the minority of the ward. Generally, in the United States, it is more proper and more safe for the guardian to get the authority of a proper court, before even converting the personal property of an infant into real estate, and certainly before attempting any transfer or any burden of the real estate. In some of the states there are general statutory provisions as to investments which guardians and others in trust may or may not make. The

guardian is not permitted to make any profit out of the ward's property, or to use it in his own business or speculations; nor can he act for his own especial advantage in any transaction relating to the property of the ward. If he make a beneficial bargain about the property or interests of the ward, the whole of the benefit must be transferred by him to the ward's estate. If he cause or suffer any waste or damage to the ward's property, he must refund in full damages, and in some states in treble damages. And in settlement of his accounts a court will sometimes charge him with compound interest, where it seems that he has himself been deriving from the use of the ward's property a profit equal to that. So if he use his ward's property in his own business, the court will decree to the ward all the capital, with all the profit it has made if this be more than interest; or if it be less or none, it will decree the capital with interest (which may be made compound if the court see fit), because it was the duty of the guardian to invest the property so that it would earn this safely. If he promise, on sufficient consideration, to pay the debt of his ward, he is personally bound, although the ward's estate fails to pay the debt, and he described himself as guardian, unless it was a specific part of the contract that he should be held only so far as the funds sufficed, or should not be held personally; and if he discharge the debt of his ward lawfully, he may charge it against the ward in his accounts, or, if he be deprived of his guardianship, or the ward become of age, he may have his action against the ward for the amount. If the ward enter into a contract or make a promise, the guardian cannot be sued thereon, but the action must be brought against the ward; and the guardian may make any lawful defence for the ward.—Besides the general guardian (whether he be appointed by will or by the court), it is common for courts to appoint a guardian *ad litem*, to represent and act for the ward in the settlement of the guardian's accounts, or in or for any other legal proceedings, where it seems proper that such appointment should be made. Guardians are also appointed generally in the United States for the insane and for spendthrifts. The manner of the appointment is regulated everywhere by statute; and the general principles already stated in reference to guardians of infants are equally applicable to other guardians, with such changes only as the difference in the nature of the case may make necessary.

**GUARINI, Giovanni Battista**, an Italian poet, born in Ferrara, Dec. 10, 1537, died in Venice, Oct. 4, 1612. Having become at an early age a professor at Ferrara, and for some time lectured on the ethics of Aristotle, he entered the service of Alfonso II. of Ferrara, and was intrusted with diplomatic missions to Venice, Savoy, the pope, the emperor, and Poland. He also served Ferdinand I. of Tuscany and the city of Ferrara. His best productions are

his comedy *L'Idropica*, his dialogue *Il segretario*, his *Rime* and *Lettere*, but particularly the drama *Il pastor fido*, which passed through 40 editions in his lifetime, has been translated into nearly all European languages, and found many imitators, although itself an imitation of Tasso's *Aminta*. An incomplete edition of his works appeared at Verona in 1737-'8 (4 vols. 4to); his *Trattato della politica libertà* was first printed at Venice in 1818, with his life by Ruggieri.

**GUARNERI**, or **Guarnerius**, the name of a family living at Cremona in the 17th century, some of whose members are celebrated as violin makers.—**ANDREA**, born about 1630, worked at his art from 1650 to about 1695. His instruments are mostly inscribed *Andreas Guarnerius fecit Cremonæ sub titulo Sanctæ Teresæ*. He was a pupil of Nicolò Amati, whose workmanship he imitated with some slight differences of detail. The tone of his instruments is sweet but not powerful. They rank in the second class.—**GIUSEPPE**, his son and pupil, in middle life made his instruments like those of Stradivarius, and later imitated his cousin Giuseppe Antonio.—**PIETRO**, second son of Andrea, lived at Cremona till 1700, and then at Mantua, and his violins bear the names of both these cities. He worked from 1690 to 1725, and his instruments were inferior to those of his father.—**GIUSEPPE ANTONIO**, nephew of Andrea, born June 8, 1683, was a pupil of Stradivarius, and the most renowned of the family. He possessed genius, but led an irregular life, much of it marked by idleness and intemperance, and a part of it spent in prison, where he died in 1745. Naturally his productions were unequal, some of them being of consummate workmanship, and others poor in material used and in method of construction. These last belong to the later years of his life, his prison days. He worked from 1725 to 1745, and his violins were mostly inscribed "Giuseppe Guarnerius, Andreæ Nepos. I. H. S." From the use of this latter symbol he was commonly known in Italy as Guarneri del Gesù. His earlier works do not show much care either in the choice of woods or the varnish. Many of those made in his middle epoch are superb, distinguished for harmony of form, beauty of color, the care with which the different woods composing the instruments were selected, and the adaptation of the curves and thickness to the production of the finest tone. To these noble instruments succeeded others inferior in all respects. Paganini and Alard were both accustomed to use Guarnerius violins at their concerts.—Violins and basses exist, dated from 1725 to 1740, made by **PIETRO**, son of Giuseppe.

**GUASTALLA**, a town of Italy, in the province of Reggio, at the junction of the Crostolo and the Po, 18 m. N. E. of Parma; pop. about 10,000. It is well built, is surrounded by walls, and contains a cathedral, eight churches, a decayed castle, a public library, a theatre, a musical academy, and several educational and charitable institutions. It was

founded by the Lombards, and during the middle ages passed successively into the hands of several Italian families and states. Subsequently it was made a fief of the German empire, and was raised to a duchy in 1621. By the treaty of Aix-la-Chapelle (1748) it was given to Don Philip of Spain, duke of Parma. In 1796 the French united it and the surrounding region to the Cisalpine republic. In 1805 Napoleon gave it to his sister Pauline, whose husband, the prince Borghese, was created duke of Guastalla. In 1815 the congress of Vienna allotted it, together with Parma and Piacenza, to the ex-empress Maria Louisa, upon whose death in 1847 it passed to the duke of Lucca, who in accordance with a previous arrangement ceded it to Modena, with which it was in 1860 incorporated into the dominions of Victor Emanuel.

**GUATEMALA**. **I.** A republic of Central America, lying between lat. 13° 50' and 18° 15' N., and lon. 88° 14' and 93° 12' W., bounded N.

by Yucatan, E. by British Honduras, the bay of Honduras, and the republics of Honduras and San Salvador, S. by the Pacific ocean, and W. by the Mexican state of Chiapas. Its greatest length from N. E. to S. W. is 325 m., greatest breadth about 300 m.; area estimated at 40,777 sq. m.; pop. about 1,200,000. The Pacific coast presents a slightly convex line extending from S. E. to N. W.; the shore being in some parts extremely low, and in others high and rocky, and bordered with a succession of rocky barriers not far from the mainland. The Atlantic shore line is very irregular, presenting here and there abrupt cliffs reaching to the very edge of the sea. The only port now frequented to any considerable extent on the Pacific side is that of San José, which, however, has only an open roadstead which affords no shelter for shipping; debarkation is at all times difficult, and sometimes

impossible for weeks together. San José is a miserable village of not more than 200 inhabitants, mostly Indians, situated at the mouth of the river Michatoya. One or two other ports further northward might be available but for the want of an adequate population. The port of Izabal, on the Atlantic side, situated on the S. shore of the gulf of Dulce, which communicates with the sea by the river Dulce, is a wretched place of about 150 houses, and owes its importance to its proximity to the capital, for all the merchandise *in transitu* to and from which it is the exclusive port of reception on that side of the republic. The shallowness of the water on the bar at the mouth of the river closes the port to large vessels. Santo Tomas, on the bay of Honduras, is the principal seaport of Guatemala; it has a picturesque harbor, sheltered by high mountains, and always affording safe and commodious anchorage for ships of the deepest draught, which moor close to the shore in six fathoms of water.—Almost the whole surface of the republic is composed of an elevated plateau, which is a continuation of the table land of Yucatan, intersected by numberless mountains, with deep and extensive valleys, particularly in the west and northwest, adjacent to Chiapas; but no continuous chain traverses the country. The depression of the table land toward the Pacific coast, however, is so rapid and presents so many steep acclivities that, when viewed from the sea, it looks like an elevated mountain range; the illusion is the more complete as the edge of the plain appears marked by a number of volcanoes, some of which are still active. Remarkable among the extinct volcanoes is the Volcan de Agua, so named from a torrent of water which burst from its crater in 1541 and overwhelmed the first city of Guatemala, the ruins of which still exist under the name of Ciudad Vieja. It has an elevation of about 14,000 ft. above the sea. Near it is the Volcan de Fuego, which vomits forth fire and smoke every day, and which, with the Volcan de Agua, and that of Amilpas (13,200 ft. high), constitutes the principal volcanic hearth of Central America. Other volcanoes are Sapotitlan and Atitlan, each nearly 13,000 ft. high. All the volcanoes of Guatemala, whether extinct or active, are in the same line with those of Nicaragua and San Salvador. The shore region consists of a strip of flat low country, not more than 30 m. broad. The slope of the plain eastward to the bay of Honduras is intersected by detached mountain groups, forming parallel ridges, which nowhere attain a greater elevation than 500 or 600 ft. above the plain, and alternate with extensive valleys. Some of these heights reach to the shores of the sea; but to the W. and N. W. of the gulf of Dulce they are entirely lost in a low plain. The table land attains an elevation of 5,000 ft. in the volcanic zone; and the maximum height is reached in the vicinity of Quezaltenango, at the S. border of the department

of Vera Paz.—Little is known of the geological structure of the country. Although gold, silver, copper, and iron are sufficiently abundant to be worked with profit, the only mining operations are those in the department of Totonicapan, where lead mines are worked in the vicinity of Chiantla, chiefly by the Indians. Salt is made from springs near Ixtatan in the same department, and in large quantities on the Pacific coast. Sulphur is found in great quantities, and jasper is abundant.—The country is watered by numerous rivers, the principal of which is the Usumasinta, whose main stream rises in the mountains near San Gerónimo, flows W. by N. 150 m., receives the waters of the Lacandones, and thence, bending N. and afterward N. W., leaves the republic and falls into the gulf of Mexico through the Lago de Términos in Yucatan. Throughout the whole course of this river in Guatemala, about 350 m., it is unfavorable to navigation. Its affluents are numerous. The Motagua, descending from the S. declivities of the same mountains as the Usumasinta, curves around their base, and, after a course of nearly 300 m., falls by several mouths into the bay of Honduras, near the E. boundary of the republic; in the upper portion it is called the Rio Grande; it is only navigable by canoes and barges. The Polochique, which rises in the hills adjacent to Coban, is a large, deep, and beautiful stream, 150 m. long; but owing to the rapidity of its current, and a bar across its mouth with but 4 ft. of water, it can only be navigated by light craft. On the W. side, a host of minor streams hurry down to the Pacific by short precipitous courses, one of them, the Michatoya, passing the port of San José. Among the many lakes, a few of which are of considerable size, are Dulce, through which the most of the shipping traffic is carried on; Amatitlan, near the town of the same name, 12 m. long by 3 m. broad, and remarkable for the large pieces of pumice stone lying along its shores and floating on its surface; and Atitlan, 30 m. long by 10 m. broad, in which no soundings have been found with a line of 300 fathoms, and which, though fed by numerous rivers, has no visible outlet. Peten lake, in Vera Paz, is about 70 m. in circuit, and dotted with a number of islands, on the largest of which stands the town of Flores. At Quirigua and other places are remarkable ruins, which attest the high proficiency of the ancient inhabitants in architecture and sculpture. (See AMERICAN ANTIQUITIES.)—The climate, excessively hot in the low and cool in the elevated regions, is generally salubrious. During the wet season, from May to October, heavy rains fall, though rarely in the forenoon. Snow is seldom seen, but frosts are frequent. The highlanders are much afflicted with goitre and cretinism. Earthquakes are frequent, and at times disastrous. The soil is exceedingly fertile; but agriculture is rudely conducted with the same kind of implements used by the first colonists. Modern machinery, however, has

been introduced by some of the wealthier planters. Maize, wheat, and other cereals, cotton, sugar cane, and tobacco are extensively produced; but the chief staple is coffee, the cultivation of which began in 1872, to take the place of that of cochineal, owing to a distemper prevailing among the insects. Indigo, cacao, and vanilla are abundant; the vine and olive thrive well in the valleys; and the supply of tropical fruits, and of those of the temperate zone also, is very plentiful. The arboreal vegetation is remarkably luxuriant. The fauna of Guatemala precisely resembles that of Mexico, to which the reader is referred. Horses, mules, black cattle, sheep, swine, and poultry are reared in large numbers, particularly in Totonicapan, Quezaltenango, and Chiquimula. The manufactures consist of cotton and woolen fabrics for home consumption, such as ponchos and *jergas* (coarse stuffs); and in Totonicapan the inhabitants are mainly occupied in making household utensils of earthenware, wood, &c. The value of the exports in 1871 was \$2,747,784. In Guatemala, as in other Hispano-American countries, the want of adequate highways is a great hindrance to the development of the material resources; the chief signs of awakening energy on the part of the government in this respect were the making of one or two new roads in 1860 and following years, and the ordering a bridge to be built over the Rio Negro in 1872.—The territory of Guatemala is divided into seven departments or *corregimientos*: Guatemala, Sacatepeque, Solalá, Quezaltenango, Totonicapan, Chiquimula, and Vera Paz. The population is made up of whites (12,000), mostly descended from the early Spanish settlers; mestizos or *ladinos* (430,000), the children of whites and Indians; negroes, pure and mixed (8,000); and pure-blooded Indians (750,000). The Indians mostly live by themselves, and the civil authorities immediately governing them are commonly chosen from their own race. The different families are mild, temperate, and industrious, unless corrupted by military chiefs, when they become rapacious, fierce, and barbarous. Indolence and licentiousness are the besetting vices of the other classes of the population. By the constitution of Oct. 19, 1851, the legislative power is vested in a congress consisting of a council of state and a house of representatives, the former with 24 members elected by the 52 members of the latter, these being elected by the people, and both for a term of four years. The executive power is vested in a president, elected for a like period, who is aided by the three ministers of interior and justice, foreign affairs, and war and finance. The chief sources of the national revenue are the customs, direct and indirect imposts, and the tobacco monopoly. The revenue amounted in 1872 to \$1,798,000, and the expenditures for the same year to \$1,785,000. In 1869 a loan of \$2,500,000 was contracted in England, including which the total debt of Guatemala

in 1872 was \$4,320,000. Besides this debt, there is another floating debt, the amount of which is unknown. Education, for a while so much neglected that of 280 public schools which existed in the republic in 1860, with about 7,000 pupils, scarcely half were open in 1865, is now again becoming an object of importance in the eyes of the government. A free school was established at Quezaltenango in 1872, toward which many citizens gave handsome contributions, and the governor his entire salary for that year. The Roman Catholic is the only religion tolerated.—The coast of this region was discovered by Columbus in 1502; the country became a Spanish dependency in 1524, and was erected into a captain-generalcy in 1527 by Charles V. In 1821 Guatemala threw off the yoke of Spain, and was annexed to the Mexican empire under Iturbide; but it became a part of the Central American federal republic in 1823. In 1839 the territory of the latter was diminished by the secession of Honduras; and eight years later Guatemala separated from the confederation, becoming an independent republic on March 21, 1847. Guatemala kept out of the many wars which, up to 1862, proved so disastrous to the other Spanish American states; but shortly after that time its finances were considerably embarrassed and its material development retarded by a succession of petty wars. In 1870 several towns and villages were severely damaged by earthquakes. In May, 1871, a revolution broke out against President Cerna, and terminated in his deposition by Granados, who was installed in the executive chair. The new government was soon obliged to exile the archbishop of Guatemala, and banish the Jesuits, who were charged with stirring up a new revolution in favor of Cerna. The port of Champerico was opened in 1872, and a road was to be constructed thence to Quezaltenango. Corporal punishment was abolished in the schools. A law passed in March restricted the liberty of the press. The collection of inland duties was abolished, and all cities were opened to commerce, except those on the frontiers of Chiapas, San Salvador, and Honduras. The order of Jesuits was declared extinct, and its property confiscated. A treaty of alliance offensive and defensive was made with San Salvador in this year, the principal stipulations of which were: mutual protection in the event of internal dissensions; the connecting of the two republics by telegraph lines; and the complete interdiction of the Jesuits. Contracts were signed for the construction of a line of railway from San José to the capital, and of six lines of telegraph, the first of which was to be from Guatemala la Nueva to the river Paz. **II. Guatemala la Nueva** (NEW GUATEMALA), a city, capital of the republic, and of a department of the same name, in lat. 14° 37' N., lon. 90° 30' W.; pop. about 40,000. This city, by far the finest in Central America, stands upon a pic-

turesque plateau 100 ft. high, 3 m. long and 1 m. broad, and occupies the northern extremity of a plain 21 m. long and 12 m. broad, with a mean elevation of 4,500 ft. above the sea. Its situation is unfavorable for commerce, being nearly 90 m. from San José on the Pacific, and 120 m. from Izabal on the Atlantic side. The volcanoes Agua and Fuego rise on either side of the town. The streets, all 40 ft. wide, are laid out with severe regularity; they cross each other at right angles, are badly paved, and not very clean; only a few of them have sidewalks. Water being scarce on the plateau, the supply for the city is brought from a distance of 9 m. by two aqueducts, and distributed by numerous fountains. On account of the frequency of earthquakes, the houses are but one story high, so that at a distance only a monotonous succession of roofs is seen,

relieved here and there by the domes and clock towers of the churches. The houses of the suburbs are mere thatched hovels, separated from each other by hedges or by open spaces. The city proper, however, contains many large and well constructed private dwellings, each surrounding a large courtyard embellished with statuary and fountains, and orange, oleander, and other fragrant and flowering trees. The internal decorations of these mansions are at once tasteful and magnificent, but glazed windows are almost unknown. The most usual building materials are a species of indurated clay, a variety of pozzuolana, and mortar, the walls being universally plastered and whitewashed. The roofs are either flat or covered with tiles; and the general style of architecture is that of the south of Spain. There are several public

Guatemala la Antigua.

squares. The largest, a rectangle 625 ft. long by 535 ft. wide, has on the E. side the cathedral and the archiepiscopal palace; on the W. the governor's palace, ministerial offices, &c., with the mint in the rear; on the N. the city hall; and on the S. a line of shops. In the centre is a fountain and basin formerly surmounted by an equestrian statue of Charles IV., the horse of which alone remains; and a great part of the area is occupied by rows of miserable little huts in which pottery, iron utensils, agave thread, and other small wares are vended, and the rent of which forms a part of the municipal revenue. In the centre of another square is the theatre, equal in size and elegance to any in Spanish America; rows of orange, oleander, and other trees of brilliant flowers and grateful fragrance surround the building, while a profusion of statues, fountains, &c., placed at intervals throughout the

square, enhances the beauty of this the fashionable evening promenade. Foremost among the public buildings is the cathedral, built in 1780, of simple and elegant design, and occupying a space of 450 ft. square. In the decoration of the interior a chaste variety is observed; and there are sculptures in wood and some fine paintings by native artists. There are 24 other churches, a hospital, and a prison. Guatemala has the largest number of educational institutions of any city in Central America; many of the wealthy people of the other states send their children here for instruction. In 1873 there were 27 common schools, mostly supported by private contributions, 16 of them being for females, and a number of schools for the working classes of all ages. Mechanical industry is little cultivated, and the instruments and tools are of the most primitive character. In spite of the diversity

of races and castes, there is little variety of costume. The wealthy adopt the European fashions. The garb of the people consists of a short woollen jacket of native manufacture, cotton pantaloons, a palm-leaf hat covered with oilcloth, and a many-colored serape or shawl. The dress of the women more closely imitates that of their superiors, except that of the Indian women, which is simple in the extreme, being a piece of blue cotton cloth drawn round the body above the hips, and occasionally a white chemise, which is often embroidered, while their hair, interbraided with a red cord, is wound around the temples. The climate is mild, but changeable; the average temperature is 65° F., the maximum 80°, and the minimum 45°. The chief occupations are agriculture and the manufacture of a few coarse woollen and cotton stuffs, earthenware, and other objects for domestic use. The city was founded in 1776, three years after the destruction of the old capital. **III. Guatemala la Antigua** (Old Guatemala), a city, once among the finest in America, and capital of Guatemala, picturesquely situated 30 m. W. of New Guatemala; pop. about 20,000. It was founded in 1524 by Pedro de Alvarado, who named it Santiago de los Caballeros, made a bishopric in 1533, and destroyed in 1541 by a flood of water from the Volcan de Agua, at the foot of which the ruins still stand, designated by the name *Ciudad Vieja* (old city). The city was rebuilt between the Volcan de Agua and the Volcan de Fuego. In 1773, the population being 60,000, it was almost totally razed by an earthquake; and the rebuilding, commenced in 1799, has since continued steadily, the surrounding country being peculiarly suited to the production of cochineal. It had before the earthquake good streets, many fine edifices, 20 monasteries, and 100 churches; the cathedral, now roofless, was 300 ft. long, 120 wide, and 70 high, and lighted by 50 windows.

**GUATEMOZIN**, the last Aztec emperor of Mexico, nephew and son-in-law of Montezuma, born about 1495, executed Feb. 15, 1525. On the death of Montezuma's brother and successor Cuiclahua, in 1520, he was elected to the vacant throne. The Spaniards, repulsed during the reign of his predecessor, were preparing for a new attack upon the Mexican capital. Guatemozin at once made energetic preparations for defence, which were barely completed when the Spanish army appeared before the city (April 28, 1521) and speedily invested it. The siege was productive of the most terrible suffering to the Mexicans; but they did not yield till exhausted by famine and greatly reduced in numbers by pestilence. Guatemozin, at the entreaties of his family, endeavored to escape by the lake of Tezcuco, but he was pursued and captured. He was first treated with respect by Cortes; but when the smallness of the booty found in the city caused the Spanish soldiers to charge their leader with being in collusion with the fallen

emperor to deprive them of their plunder, Cortes permitted him to be put to the torture, as though to force from him either a confession or denial concerning the treasure. Guatemozin bore the torture (the burning of his feet at a slow fire) with great firmness, and is said to have answered the complaints of the cacique of Tacuba, who suffered with him, with the stoical query, "Do you think, then, that I am taking my pleasure in my bath?" All that was extorted from him was the information that "much treasure had been thrown into the water;" but this statement was probably intended to mislead his captors, as the lake and canals were dragged without result. As nothing was to be gained from the prisoner, he was allowed to live at Mexico in an honorable captivity. When Cortes began in 1524 his expedition for the conquest of Honduras, he took Guatemozin with him; and he was thus a witness of the misfortunes that attended this march of his conquerors. Late in the campaign two Spanish nobles accused him and his Mexican companions of having formed a plot to assassinate the Spanish chiefs, Cortes among the rest. The latter ordered them to be at once brought before him, and after a brief inquiry into the accusation, which was not sustained by proof, he commanded their execution. According to Prescott they were hanged on a large *ceiba* tree standing by the roadside; according to other authorities, they were executed with considerable ceremony in the public square of Teotilac. The widow of Guatemozin was thrice married after his death, in each case to a Spaniard.

**GUATUSOS**, a tribe of Indians, living on the banks and head waters of the Rio Frio, which flows into Lake Nicaragua at its S. extremity. The country of these Indians, who are popularly supposed to have comparatively fair complexions and red hair, has never been penetrated. The attempts made by the Catholic missionaries and the governors of Nicaragua to reach them, though often renewed, have always been repulsed. A body of men under the commander of the fort of San Carlos endeavored to enter their country in 1849, but they were driven back. There are some reasons for believing that they are of the same Aztec family which occupied the western shores of Lake Nicaragua, and that they still preserve their original language and habits.

**GUAVA** (Span. *guayaba*), a name for trees of the genus *psidium*, belonging to the myrtle family. There are about 100 species of the genus, which grow in tropical and sub-tropical America, though the number that bear edible fruit is small. The one best known as the guava is *P. guaiava*, of which there are several cultivated forms, differing in the size, shape, and quality of their fruit. It is a small tree, from 9 to 15 ft., seldom over 20 ft. high, with angular branches, and an abundance of elliptical pointed leaves, which are covered below with a velvety down. The flowers are solitary

or three together in the axils of the upper leaves, about an inch in diameter, white, and with an agreeable odor; the fruit, usually about an inch in diameter, varies in size and shape; the principal cultivated varieties are called *maliforme*, apple-shaped, and *pyriforme*, pear-shaped, from

Guava (*Psidium Cattleianum*).

the form of the fruit. Guavas are bright yellow, exceedingly fragrant, and filled with a yellowish or reddish seedy pulp, which has an acid-sweet flavor, but is rather disappointing to the taste after the sense of smell has been gratified by its odor. The guava grows abundantly in the West Indies, has been acclimated in Algeria and other warm countries, and is cultivated under glass for its ornamental foliage and flowers as well as for its fruit. Cattley's or the purple guava, *P. Cattleianum*, though brought to Europe from China, is probably a native of South America; it is much more hardy than the common guava, and though its claret-colored fruits, with a pitted rind, are smaller and more acid, it produces them in greater abundance. The wood of the guavas is close-grained, but their principal value is in their fruit, which is consumed in the fresh state, and large quantities are made into jelly.

**GUAXACA.** See OAJACA.

**GUAYANA.** See GUIANA, and VENEZUELA.

**GUAYAPE,** a river of Honduras, an affluent of the Patuca, in the department of Olancho.

This river has been celebrated from the earliest period for its rich gold washings, which are worked by the natives in a rude manner. All the streams in Olancho carry gold in their sands, but none have an equal celebrity in this respect with the Guayapec.

**GUAYAQUIL,** a maritime city of the republic of Ecuador, capital of the province of Guayas, 150 m. S. W. of Quito; pop. about 26,000. It is built on the W. bank of the bay of Guayaquil, on which it has a front of a mile and a half, and is traversed by four creeks, crossed by three wooden bridges, two of which separate the old town from the new or more modern portion. Many of the streets are tortuous, but a few are regular, cutting each other at right angles, and all are lighted with gas; most of the houses are of wood, roofed with tiles, and rarely of more than two stories. Portals or covered arcades surround every block or square of houses. The principal public buildings are the cathedral and six other churches, the governor's palace, city hall, prison, two hospitals, and barracks. There are two colleges, a naval and a number of common schools, and a new school for females commenced in 1872. An association for mutual instruction was organized in the same year. The town has an orphan asylum and several other benevolent institutions. The port, formed by the river and its estuary, is very commodious, presents good anchorage for vessels of any draught, and is monthly visited by an average of 17 steamers. In 1870, 125 vessels of all kinds and flags were entered, the aggregate tonnage being 55,310. A large number

Cathedral of Guayaquil.

of ships were formerly built here. There are several factories employing steam power, including one for artificial ice and a foundry. Provisions are brought each morning in canoes, which literally throng the river, and give it the appearance of another town. The heat is

excessive; epidemics are of frequent occurrence; and during the rainy season, from December to May, noxious insects and reptiles infest the city and surrounding country. Many and important improvements were commenced in 1872, mostly of a hygienic nature. Two lighthouses were built in 1873, one on the island of Santa Clara and the other on the island of Puná. Three forts defend the town. Guayaquil is the chief commercial centre of Ecuador; the principal articles of export are cacao, cotton, coffee, tobacco, nuts, fruits, jipijapa (or Panama) hats, sarsaparilla, India rubber, and pearl shells. In 1872 there were shipped 181,973 quintals of cacao (the total crop of which was 187,238 quintals), 75,000 of India rubber, 58,451 of pearl shell, 22,531 of vegetable ivory, 6,600 of coffee, and 39,728 lbs. of sarsaparilla. The value of the exports to Great Britain in 1868 was \$510,505; in 1869, \$1,320,000; in 1870, \$692,055; in 1871 \$1,388,830; in 1872, \$1,219,200; total in five years, \$5,130,590. The imports from Great Britain during the same period amounted to \$1,422,045. A new road from Guayaquil to Quito is in rapid progress (1874), and a railway has been commenced over a part of the same route. A quicksilver mine and coal mines have been discovered near the city.—Guayaquil was conquered by Sebastian Belacazar in 1535. Of the numerous fires which have occurred since 1624, that of 1764 was the most destructive, the place having been almost entirely abandoned for a time. In 1770 a royal order was issued for its restoration.

**GUAYAQUIL**, a river of Ecuador, flowing wholly within the province of Guayas, and giving its name to the preceding city. It is formed by the union of a great number of small streams which rise among the Andes; enters the Pacific through the gulf of Guayaquil in lat. 2° 27' S.; is navigable about 110 m. to Caracol; and in the upper part of its course is known successively as the Caracol and Babahoyo. It is subject to overflow, and is encumbered by a bar 12 m. from its mouth, and by shifting sands.

**GUAYAS**, a maritime province of Ecuador, bordering on the Pacific and Peru, and on the provinces of Manabí, Asuay, Los Rios, and Loja; pop. about 37,000. It is drained by four or five rivers, of which only the Guayaquil is navigable to any considerable distance from the sea. The soil is extremely fertile; rice, cacao, cotton, tobacco, and tropical fruits are largely produced. The northern portions are marshy; in the southwest are vast forests affording the finest species of American precious woods and excellent building timber. The climate is excessively hot, and rain falls almost incessantly from December to May. Fevers prevail.

**GUAYMAS**, a town of Mexico, in the state of Sonora, on Yaqui bay, gulf of California, in lat. 28° N., lon. 110° 50' W.; pop. about 3,000. It is surrounded by hills, and is hot and unhealthy. Most of the streets are narrow and dirty, and there are no buildings worthy of note. The

port is commodious, has excellent anchorage, and is frequented by many vessels. Its foreign trade is large, as it is the port of entry for the states of Sonora and Chihuahua. The chief exports are wheat, flour, and hides. The Indians carry on a profitable fishery in the bay.

**GUBBIO** (anc. *Igvium* or *Eugubium*), a town of Italy, in the province of Perugia, near Mount Calvo, 30 m. N. E. of the city of Perugia, and 110 m. N. of Rome; pop. about 6,000. It contains a cathedral, several churches, about 20 convents, and a theatre; and silk and woollens are manufactured. During the middle ages it had a population of 30,000, and was the seat of a fine school of painting. It is supplied with water from a reservoir formed by a dam across the valley between Mounts Ingino and Calvo, which is one of the most remarkable specimens of mediæval engineering. There is a museum containing many Pelasgic remains. The famous Eugubian tablets, with inscriptions in the Umbrian, Etruscan, and Latin languages, which have been variously interpreted by antiquaries, were discovered in 1444 about 8 m. from the town. In the 14th century Gubbio became a part of the Papal States, with which it passed to the kingdom of Italy. The ancient Igvium was considered by the Romans to be of great strategical importance, and was prominent in the early part of the civil war between Caesar and Pompey.

**GUBEN**, a town of Prussia, in the province of Brandenburg, at the junction of the Neisse and the Lubst, 25 m. S. by E. of Frankfort-on-the Oder; pop. in 1871, 21,423. It contains several churches and a gymnasium; has extensive manufactories of cloth and tobacco, and an active trade, especially in red wines, produced on the adjoining Neisse hills. The Hussites devastated the place in 1434 and 1437, and the Swedes occupied it in 1631 and 1642.

**GUBITZ, Friedrich Wilhelm**, a German author, born in Leipsic, Feb. 27, 1786, died June 5, 1870. He studied theology, worked as a type founder, printer, and engraver, became professor of wood engraving at the Berlin academy of fine arts in 1805, and afterward engaged also in bookselling. His principal works are *Gedichte* (2 vols., Berlin, 1859), *Wirklichkeit und Phantasie* (4 vols., 1862), and *Erlebnisse* (3 vols., 1868-'79). His most popular play is *Der Kaiser und die Müllerin*. As a theatrical critic and the founder of several periodicals devoted to dramatic literature, he contributed much to the improvement of the stage. His *Deutscher Volkskalender*, which he edited for many years, became exceedingly popular, and found numerous imitations.

**GUDGEON**, a cyprinoid fish of the genus *gobio* (Cuv.), found chiefly in the fresh-water streams and lakes of central and temperate Europe. It is characterized by a lengthened, rounded body, with short dorsal and anal fins without serrated rays; a labial barbel at each corner of the mouth; pharyngeal teeth, conical, slightly curved at the tip, and in two rows; and a

wide, flattened head, with an obtuse snout, and the lower jaw the shorter; the swimming bladder is large and double. The common gudgeon (*G. fluviatilis*, Cuv.) is 7 or 8 in. long, greenish brown above and on the sides, white below, the pectorals, ventrals, and anal grayish white tinged with brown, and the dorsal and caudal pale brown, with darker spots. It occurs in shoals in the gravelly waters of Europe. The food consists of worms, aquatic insects and larvae, small mollusks, ova, and fry; the eggs are

Gudgeon (*Gobio fluviatilis*).

laid between April and August, and the young grow to a length of about 5 in. the first year. It is much esteemed for its delicate flavor, and affords good sport to the angler; it will bite at all times of day, but best in the morning and evening, and in cloudy weather; the line must be very fine, and the hook kept within an inch of the bottom; the best bait is the common red dunghill worm. Five other species are described in Europe and Asia, and one from the Niagara river (*G. cataractæ*, Val.), about 5 in. long; the color of this above is gray, plumbeous on the sides, silvery white below, and the fins gray.

**GUDIN**, Jean Antoine Théodore, a French painter, born in Paris, Aug. 15, 1802. He was a pupil of Girodet-Trioson, and from the outset of his career devoted himself mainly to sea pieces. Among his best productions are a view of "Mont St. Michel at High Tide;" "A Steamboat landing Passengers at Dover;" "A Gale, Jan. 7, 1831, in Algiers Harbor;" "La Salle discovering Louisiana;" "A Naval Battle in the Chesapeake;" and "A Shipwreck on the Coast of America."

**GUEBRES**, or **Ghebers** (Turkish, *Ghiours*, *Ghauris*, and *Giaours*, infidels), a name applied to those Persians who adhered to the ancient religion of Zoroaster after the great majority of the nation had been converted to Mohammedanism, and who are generally known by Europeans as fire worshippers. They call themselves *Beh-Din*, "those of excellent belief." The Arabs completed the conquest of Persia in the 7th century, and the great mass of the nation adopted the faith of the conquerors. Those who refused to do so were subjected to persecution. Some of them took refuge in the wilderness of Khorasan, and others in Kohistan. The latter in the 9th century emigrated to In-

dia and settled in the neighborhood of Surat. Their descendants still inhabit the same region, and are called Parsees. (See **PARSEES**.) The descendants of those who remained in Persia have gradually decreased in numbers and sunk into ignorance and poverty, though still pre-

Guebre Priests.

serving a reputation for honesty, chastity, industry, and obedience to law, superior to that of the other Persians. They are estimated to number about 7,000. They reside chiefly in Yezd and the surrounding villages, but are found here and there over the whole of Persia. A celebrated temple of the Guebres is situated near the Russian town of Baku, on the Caspian sea. (See **BAKU**.) For an account of their religion, see **ZENDAVESTA**, and **ZOROASTER**.

**GUEBWILLER**. See **GEWELLER**.

**GUELDERLAND**. See **GELDERLAND**.

**GUELDER ROSE**, the name of a garden form of *viburnum opulus*, a shrub which in its wild state is common in the cooler parts of America, Europe, and Asia. It grows with an upright habit from 2 to 10 ft. high, has opposite three-lobed leaves, and each branch terminated by a broad cluster (cyme) of white flowers, the majority of which are small and perfect, while those upon the margin of the cluster have corollas many times larger than the others, and showy, but, having neither stamens nor pistil, are sterile; the perfect flowers are succeeded by a berry-like spherical fruit having one flat smooth stone; it is bright red, very acid, and is sometimes cooked with sugar under the name of high or bush cranberry. The wild shrub is worth cultivating, as its flowers are pleasing, its bright fruit showy, and its leaves in autumn turn to a dark crimson. In the guelder rose all the flowers of the cluster are like the marginal ones of the wild plant, and the cymes become spheri-

cal masses of crowded white petals, which have given to it the popular name, and the one most used in this country, of snowball, and with the French of *boule de neige*. The garden form is supposed to have originated in Gelderland, but it has been so long in culti-

Guelder Rose (*Viburnum opulus*).

vation that its history is obscure. A form with variegated foliage is cultivated, and there has recently been introduced a variety with very large flower clusters as *V. macrocephalum*. The Japanese *viburnum plicatum* has finer foliage and flowers than the common plant. All are of the easiest culture.

**GUELPH**, a town and inland port of entry, capital of Wellington co., Ontario, Canada, 45 m. W. S. W. of Toronto; pop. in 1871, 6,878. It is built upon several hills, on the river Speed, and on the Grand Trunk railway, at the terminus of the Wellington, Grey, and Bruce line, and the Galt and Guelph branch of the Great Western railway. The court house and several other buildings are of limestone quarried in the vicinity. The surrounding country is a rich agricultural region, and wheat and flour are shipped in considerable quantities. The river here falls about 30 ft., furnishing abundant water power. There are several flour mills, saw mills, planing mills, breweries, and manufactories of woollens, iron castings, machinery, agricultural implements, leather, sewing machines, musical instruments, wooden ware, &c. There are three branch banks, a library and reading room, two daily and three weekly newspapers, and churches of seven denominations.

**GUELPHS AND Ghibellines** (Ger. *Welfen*, Ital. *Guelfi*, and Ger. *Wiblingen* or *Waiblingen*, an estate belonging to the Hohenstaufen family, in the modern Würtemberg), the names of two celebrated factions in Italy and Germany during the middle ages. Guelph or Welf is a baptismal name in several German families, but more particularly known in the his-

tory of a line of princes originally Italian, and traced to the 9th century. They emigrated to Germany two centuries later, and became divided into two branches, both possessing large estates in southern Germany, between the Brenner and St. Gothard. The present royal family of England and the ducal line of Brunswick in Germany trace their descent to a Guelphic princess, Kunigunde, the heiress of one of the branches, who became the wife of Alberto Azzo II., prince of Este, born in 996. By this marriage the estates of the Guelphs were united to those of the Este princes in Lombardy. The son of Kunigunde, Guelph IV., duke of Bavaria, inherited also the estates of the senior branch of the Guelphs, called the Guelphs of Altorf, and became thus the founder, as it were, of the reunited Guelphs. The emperor Henry IV. bestowed upon him the duchy of Bavaria, but soon incurred his enmity by restoring a part of the Bavarian possessions to their rightful duke, Otho II. Guelph took up arms against the emperor, and, in league with other discontented princes, defeated him in several battles. They were afterward reconciled, and Guelph joined in the first crusade and was present at the taking of Jerusalem. He died in Cyprus in 1101, on his return. Guelph II., his son, at first supported the emperor Henry IV., but soon deserted him and embraced the cause of his rebellious son Henry V., of whom he became a great favorite. He died in 1120, without children; and the duchy of Bavaria was inherited by his brother, Henry the Black, who transmitted it to his son, Henry the Haughty, in 1126. The latter married the daughter of the emperor Lothaire, and received from his father-in-law the duchy of Saxony. He subsequently disputed the crown of Germany with Conrad III., was deprived of most of his possessions, and was put under the ban of the empire (1139). His brother, Count Guelph of Altorf, guardian of the famous Henry the Lion, his nephew, the son of Henry the Haughty, at that time but ten years of age, endeavored to recover for his ward possession of the confiscated duchies. Bavaria had been bestowed upon Leopold of Austria; Saxony upon Albert the Bear, of Brandenburg. The Saxons demanded a Guelphic prince; and Albert, at the emperor's desire, formally resigned the duchy to the youthful heir. In Bavaria Count Guelph was less successful. He was put under the ban of the empire as a rebel in 1140, but ventured nevertheless to give battle to Conrad's troops, near Weinsberg, and was defeated. In this action were first heard those famous battle cries, which afterward became the most noted in Europe: "Strike for the Guelphs;" "Strike for the Ghibellines." The wars of the Guelphs and Ghibellines, originating thus, soon became of much wider political consequence. In Germany they were of no great duration, but they long raged in Italy. Throughout the peninsula the family of the Guelphs found partisans weary of the yoke of

the German emperors. The pope, irritated by German opposition in the matter of the investitures, declared for the Guelphs. The Lombard cities formed their league in favor of the Guelphic princes, while a similar league, under the patronage especially of Pavia, declared for the Hohenstaufen, by this time better known as the Ghibellines. The latter prevailed for many years. The emperor Frederick Barbarossa, notwithstanding the efforts of Pope Alexander III., took Milan, and reduced the whole of Lombardy. The contest was resumed under Frederick II. His grandson Conradin was the last of the race of Hohenstaufen. The Ghibellines had rallied about this unfortunate prince, who, at the age of 16, was beheaded at Naples by order of his perfidious enemy, Charles of Anjou (1268). The Guelphs meanwhile had been driven from both of their German duchies. The grandson of Henry the Lion, Otho the Child, had done homage to Frederick II. in 1235. He had been thereafter created by this emperor duke of Brunswick, and held some remnant of his ancestors' estates as fiefs of the empire. From him were descended the reigning houses of England, Hanover, and Brunswick. Twenty years later the contest became but a private feud of various Italian factions; of families sometimes in the same city. In 1259 the marquis of Este, a Guelph, triumphed over a Ghibelline faction of Verona, headed by Ezzelino the Ferocious. (See EZZELINO.) At Milan, in 1277, the Torriani, Guelphic chiefs, were compelled to surrender power to the Visconti, representing the Ghibellines. At Florence, in 1258, Silvestro de' Medici, of a Guelphic faction known then as the blacks (*neri*), against the whites (*bianchi*), by which name the Ghibellines had come to be designated, deprived the family of the Uberti of their power, and gave to the Florentines a republican government. Pisa, after a disastrous war with Genoa, fell under the domination of the Guelphs about 1284, but only for a time. Rome, in the time of Rienzi (middle of the 14th century), for years vacillated between oligarchy and democracy, Ghibellines and Guelphs, as those factions were now designated. In general the former were partisans of imperial and feudal hierarchy; the latter of the church and national independence. Their contests, after desolating Italy for 400 years, yielded to self-exhaustion. The French invasion of 1494 was mainly instrumental, however, in diverting the national mind, and interrupting a party spirit unsurpassed in the histories of obstinate and cruel domestic wars.—In 1815, shortly after Hanover was erected into a kingdom, the prince regent, afterward George IV. of Great Britain, in honor of the Guelphic founders of the house of Brunswick-Hanover, established an order of knighthood, known as the Guelphic order of Hanover. The insignia are a cross of gold, bearing a medallion, on the red field of which is a silver horse upon a green mound (sinople); the motto is: *Nec aspera terrent*.

**GUENON.** See MONKEY.

**GUÉPARD.** See LEOPARD.

**GUÉRANDE**, a town of France, in the department of Loire-Inférieure, 38 m. N. W. of Nantes; pop. in 1866, 6,749. It is now 3 m. from the sea, but it once had a harbor and was a place of importance. It is surrounded by massive walls flanked with imposing towers, and has four gates. In the environs are extensive salt marshes, which are below the level of the sea and are protected by dikes, through which the water is admitted at high tide into basins and evaporated. The annual production of salt is over 80,000 tons. Guérande has also manufactories of cotton and linen goods, herring fisheries, and a brisk trade in wine. It was founded in the 6th century, and was fortified in 1431.

**GUERAZZI.** See GUERAZZI.

**GUERCINO** (GIOVANNI FRANCESCO BARBIERI), an Italian painter, born at Cento, near Ferrara, in 1590, died in Bologna in 1666. An accident deprived him in infancy of the use of his right eye, whence he gained his name Guercino (little squint-eye). While a boy he manifested a remarkable talent for painting, and according to common report became a disciple of the Carraccis at Bologna, although Cremonini and Benedetti Gennari, artists of little note, seem to have been the masters from whom he acquired chiefly the rudiments of the art. Writers have distinguished three different styles in Guercino's paintings, of the first of which few specimens are to be found, being the least known, while the second and third embrace the greater portion of his works. His earlier pictures show the influence of Caravaggio; but by intercourse with prominent artists of other schools he formed what is known as his second style. In this style are painted his "St. Petronilla," formerly in St. Peter's; the "Aurora," at the villa Ludovisi; "St. Philip of Neri," at Rome; the "Resurrection," at Cento; "St. Helena," at Venice; and above all his frescoes on the dome of the cathedral at Piacenza. His third style, a palpable imitation of Guido, is feeble and languid. He was exceedingly industrious, and among his works are enumerated 106 altarpieces, 144 large compositions, and an immense number of Madonnas, portraits, and landscapes. He also left numerous drawings. He founded a school, which flourished for a number of years at Cento.

**GUÉRET**, a town of France, capital of the department of Creuse, near the left bank of the Creuse, 35 m. N. E. of Limoges; pop. in 1866, 5,126. It has a communal college, normal school, public library, and museum; manufactories of combs, bone black, buttons, and potash; distilleries and tanneries; and a brisk trade in coal, lumber, butter, and fruits. Guéret was built around an abbey founded about 720.

**GUERICKE**, Heinrich Ernst Ferdinand, a German theologian, born at Wettin, Prussia, Feb. 23, 1803, died Feb. 4, 1878. He graduated at the university of Halle, and was appointed

professor there in 1829. He was an opponent of the union between the Protestant churches in Prussia, and was dismissed in 1835, but resumed his academical functions in 1840. He afterward edited the *Zeitschrift für lutherische Theologie*, in concert with Rudelbach. His principal works are: *Historisch-kritische Einleitung in das Neue Testament* (1843), the second part of which appeared in Leipsic in 1854 under the title of *Gesamtgeschichte des Neuen Testaments, oder Neutestamentliche Isagogik* (3d ed., 1868); *Allgemeine christliche Symbolik* (3d ed., 1861); *Lehrbuch der christlichen Archäologie* (1847; 2d ed., 1859); and *Handbuch der Kirchengeschichte* (9th ed., 3 vols., 1867). The last named work has been translated by Prof. Shedd (Andover, 1857).

**GUERICKE, Otto von**, a German natural philosopher, born in Magdeburg, Nov. 20, 1602, died in Hamburg, May 11, 1686. He was for 35 years burgomaster of Magdeburg. In 1650 he invented the air pump, subsequently perfected by Robert Boyle and others. He illustrated the force of atmospheric pressure by fitting together two hollow brass hemispheres, which, after the air within them had been exhausted, could not be pulled apart. He also invented a species of barometer. As an astronomer he was one of the first to express the opinion that the return of comets might be calculated. He published several treatises in natural philosophy, of which *Experimenta Nova, ut vocant Magdeburgica*, &c. (Amsterdam, 1672), contains his experiments on a vacuum.

**GUÉRIN, Jean Baptiste Paulin**, a French painter, born in Toulon, March 25, 1783, died in Paris, Jan. 16, 1855. He was the son of a locksmith, and at first made a living as a workman. Having saved enough money to go to Paris, he accepted a menial office in the studio of Gérard, where he secretly executed a large picture, "Cain after the Death of Abel," which was purchased by the government. Among his paintings, some of which are mythological, while most of them are of a religious character, are the "Descent from the Cross," which was presented to the Roman Catholic cathedral in Baltimore, U. S., by Louis XVIII.; "Anchises and Venus," purchased by the French government in 1822; and "Adam and Eve expelled from the Garden of Eden," one of the masterpieces of the French school. He left also many portraits, those of Charles X. and Lamennais among the number.

**GUÉRIN-MÉNEVILLE, Félix Édouard**, a French naturalist, born in Toulon, Oct. 12, 1799, died in Paris early in 1874. He studied under Cuvier, and became in 1850 professor of entomology at the collège de France, and subsequently was inspector general of silk culture. His works include *Iconographie du Règne animal de M. le baron Cuvier* (7 vols., 1830-'44); *Magasin de zoologie, d'anatomie comparée et de paléontologie* (26 vols., 1831-'44); and *Genera des insectes* (6 vols., 1835). A. Percheron was associated with him in the last named publica-

tion, and Eugène Robert in the *Guide de l'éleveur des vers à soie* (1856).

**GUERNSEY**, the westernmost of the Channel islands, belonging to Great Britain, and lying in the English channel, 28 m. from the N. W. coast of France, and 65 m. from England, between lat. 49° 24' and 49° 33' N., and lon. 2° 30' and 2° 40' W.; area, 25 sq. m.; pop. in 1871, 30,593. The surface toward the north is low and level, but toward the south is hilly. The coast is deeply indented with excellent harbors, and in some places rises into precipitous cliffs 270 ft. high. The climate, though variable, is temperate and healthy. The soil is fertile, but agriculture is generally in a backward state. The principal productions are wheat, barley, oats, rye, potatoes, fruit, cider, wine, butter, pigs, and cattle. The most important exports are apples, cider, wine, potatoes, and granite. The inhabitants are a simple and thrifty race, and speak a dialect of that Norman French which has been obsolete for centuries save in these islands. The military government is vested in a lieutenant governor, who represents the sovereign in the assembly of the states. The legislative body, called the states, is composed of 32 members, two of whom are appointed by the crown. The states vote the ordinary expenses, but new taxes must be sanctioned by the crown. Victor Hugo resides in this island. Capital, St. Peter Port, or Peter-le-port.

**GUERNSEY**, an E. county of Ohio, drained by branches of Muskingum river; area, 460 sq. m.; pop. in 1870, 23,838. It has a hilly surface, with a soil of moderate fertility, and abounding in coal. The slopes afford good pasturage, and in many places are covered with vineyards from which wine is produced. It is traversed by the central Ohio division of the Baltimore and Ohio railroad. The chief productions in 1870 were 175,051 bushels of wheat, 685,758 of Indian corn, 325,676 of oats, 81,885 of potatoes, 696,183 lbs. of butter, 617,551 of wool, 474,178 of tobacco, and 31,376 tons of hay. There were 7,047 horses, 6,411 milch cows, 8,673 other cattle, 151,848 sheep, and 15,222 swine; 13 manufactories of carriages and wagons, 10 of saddlery and harness, 2 of salt, 2 of sashes, doors, and blinds, 6 of tin, copper, and sheet-iron ware, 2 of woollen goods, 6 flour mills, 6 saw mills, 7 tanneries, and 5 currying establishments. Capital, Cambridge.

**GUÉROULT, Adolphe**, a French journalist, born at Radepon, Jan. 29, 1810, died in Paris, July 22, 1872. He was the son of a wealthy manufacturer, and early devoted himself to literary pursuits and to the advocacy of St. Simonism. He was the correspondent of the *Journal des Débats* in Spain and in Italy for many years. In 1842-'7 he was consul at Mazatlan, and in 1847-'8 at Jassy; and in 1852 he became sub-chief of the *crédit foncier*. As a member of the corps législatif (1863-'9) and as the editor-in-chief of the *Opinion nationale*, which he founded in 1859, he exerted great influence

in behalf of the so-called imperialistic democracy, and as a strenuous opponent of ultramontaniam. With other deputies he was denounced in 1869 by M. de Kervéguen for his alleged friendly attitude toward Prussia, but was vindicated by the assembly. Among his publications is *Discours prononcés au corps législatif* (Paris, 1869).

**GUERRAZZI, Francesco Domenico**, an Italian author and politician, born in Leghorn in 1805, died in Rome, Sept. 23, 1873. He was educated as a lawyer, and at the age of 22 brought himself into notice by writing *La battaglia di Benevento*, a historical romance (Florence, 1828). Being an ardent republican, he took part in a conspiracy, and in 1831 was thrown into prison, where he wrote *L'Assedio di Firenze* and *Isabella Orsini* (the latter translated into English by Luigi Monti, New York, 1859). Upon his discharge he removed to Florence, where he became a successful lawyer. Among his publications while there were *Veronica Cybo*, *Serpicina*, and *I Nuovi Tartufi*, and a drama, *I Bianchi ed i Neri*. He took a leading part in the revolution of 1848, and was imprisoned for a short time. He had no sooner recovered his liberty than he placed himself in relation with Mazzini, Gioberti, and other agitators, founded a republican journal at Florence, was chosen a deputy to the national assembly of Tuscany, and appointed minister of the interior in October, 1848. After the departure of the grand duke from his capital in February, 1849, Guerrazzi became a member, and in March the chief of the provisional government, which was overthrown in the following month. He was arrested April 14, and removed in June to the state prison of Volterra, where he was detained till July, 1853, and wrote a defence of his political course, *Apologia della vita politica di F. D. Guerrazzi* (Florence, 1851). After trial he was sentenced to perpetual banishment, and proceeded to Marseilles. Not being permitted to reside there, he went to Bastia in Corsica, where he wrote *Beatrice Cenci* (Pisa, 1854; English translations by Monti and Mrs. Watts Sherman, New York, 1858). His next place of residence was in Piedmont, where he published *L'Asino*, a satirical journal. As member of the parliament which assembled at Turin, and afterward of the Italian parliament, he belonged to the extreme left. He also published *Pasquale Paoli* (2 vols., Milan, 1865).

**GUERRERO. I.** A state of Mexico, bounded N. by the states of Michoacan, Mexico, and Puebla, E. by Oajaca, S. by the Pacific, and W. by Michoacan; area, 24,226 sq. m.; pop. in 1869, 241,860, mostly Indians. This state, formed in 1849 of three districts from Mexico, two from Puebla, and one from Michoacan, is one of the most picturesque in the republic. It has a very irregular surface, being traversed from E. to W. by the Cordillera of the Sierra Madre, which throws off numerous spurs, many extending almost to the coast, especially in the

western half, where also the greatest altitude is attained, and some trending N. until they are lost in Michoacan, or confounded with the gradual descending slope of the Mexican plateau. There are few valleys, and these of inconsiderable extent. The chief river is the Rio de las Balsas, which rises in Tlascala, enters the state near the N. E. corner, and flows first W. and then S. W., and falls into the Pacific by two mouths, half way between Acapulco and Manzanillo, forming the whole dividing line with the state of Michoacan. It is not navigable except by small craft. Silver is the most important mineral, but of the numerous mines formerly in operation, only 13 are now worked, partly owing to the inferior quality of the metal in the others, and partly to the want of capital. Attention has within a few years been called to important gold mines at San José and Piedras Blancas. Cinnabar is abundant elsewhere, as are likewise lead, sulphur, saltpetre, and copperas; and anthracite is found in Chilpancingo. The climate varies from cold to extremely hot, according to elevation. Intermittent and other fevers prevail in most localities; goitre along the banks of the Balsas, and in the vicinity of the capital a species of leprosy. The soil is very fertile, and vegetation, particularly arboreal, is rich and varied, and there are extensive virgin forests, presenting excellent timber and many species of precious woods. Maize and beans are the chief agricultural productions, the former yielding three large crops annually; cotton, the sugar cane, coffee, cacao, yuca, and tobacco are also cultivated; and cochineal and indigo are extensively produced. Agriculture is, however, little attended to save in the central portions of the state. The chief articles of export are cochineal, indigo, cacao, wool, and hides; the imports consist of cotton and silk fabrics, spices, and hardware. The foreign trade, once very important, is carried on through the port of Acapulco. Manufactures are limited to coarse cotton and woollen stuffs, rude agricultural implements, and household utensils. Many of the inhabitants are miners; and on the coast numbers are engaged in pearl fishing. **II.** A city, capital of the state, formerly called Tixtla or Tixtlan, in a narrow gorge between two mountains in the Sierra Madre, 152 m. S. by W. of Mexico; pop. in 1869, 6,501. Raised to the rank of a city upon the formation of the state in 1849, this place is as yet of little importance in any respect. The chief occupations of the people are coarse manufactures, mining, and agriculture. Notwithstanding its elevation, 5,000 ft. above the sea, its climate is hot; intermittent fevers and goitre are common, and a species of leprosy called *pinto* prevails to an alarming extent among the lower classes.

**GUERRERO, Vicente**, president of Mexico, born at Tixtla about 1770, executed at Cuilaipa, Feb. 14, 1831. He was a mulatto, and origi-

nally a slave. In the struggle for the independence of Mexico he exhibited great courage, and after the death of Mina became one of the leaders of the insurgents. In 1820 he entered the service of Iturbide, upon whose overthrow in 1823 he gave in his adherence to the provisional government and to the republic. In 1827 he was a candidate for the presidency, but was defeated by Pedraza by a majority of two votes in the electoral college. The partisans of Guerrero alleged that the election was carried by fraud, and rose in insurrection. Pedraza resigned in 1829, and Guerrero took possession of the presidency. On Sept. 15 of that year he issued a proclamation abolishing slavery. The next year, a Spanish force having invaded Mexico, dictatorial power was conferred upon Guerrero, and his troops under Santa Anna defeated the Spaniards; but thereupon Bustamante and Santa Anna, on pretence that he ought not to have prolonged his dictatorship after the defeat of the Spaniards, revolted against Guerrero, who was deserted by his troops and compelled to take refuge in his hacienda at Tixtla. He was popular, and the people rallied to his support. He renewed the contest, but it was brought to a sudden close through the agency of a Genoese ship captain, who invited him to a dinner on board his vessel at Acapulco, and betrayed him to his enemies. He was tried by a military commission and shot.

**GUESCLIN.** See **Du GUESCLIN**.

**GUESS, George, or Sequoyah**, a half-breed Cherokee Indian, inventor of the Cherokee alphabet, born about 1770, died in San Fernando, northern Mexico, in August, 1843. He cultivated a small farm in the Cherokee country of Georgia, and was occupied as a silversmith when in 1826 he invented a syllabic alphabet of the Cherokee language, which consisted of 85 characters, each representing a single sound in the language. This is probably the most perfect alphabet ever devised for any language. For the characters he used, as far as they went, those which he found in an English spelling book, although he knew no language except his own. A newspaper called the "Phoenix" was established, a part of it printed in Cherokee, using the alphabet of Guess. A part of the New Testament was also printed in this character. He was not a Christian, and is said to have regretted his invention when he found it used for this purpose. He accompanied his tribe in their migration beyond the Mississippi, and resided for some time in Brainerd. In 1842 he went with other Indians into Mexico.

**GUEST, Edwin.** See supplement.

**GUETTÉE, Wladimir**, a French historian, born in Blois about 1815. He took orders, and was for several years a parish priest. After the revolution of 1848 he edited at Blois a journal entitled *La Démocratie*. Subsequently he went to Paris, where he became chaplain in several hospitals, but was removed on account of his Jansenist opinions. He contributed largely to

the *Observateur Catholique*, the leading organ of the Gallican church. His principal works are: *Histoire de l'Église de France* (12 vols., 1847-57); *Jansénisme et jésuitisme* (1857); *Histoire des jésuites* (4 vols. 8vo, 1858-72); *Papauté temporelle condamnée par le pape St. Grégoire le Grand* (1861); *Réputation de la prétendue Vie de Jésus de M. Renan* (1864); *De l'Encyclique du 8 décembre, 1864* (1865); and *Exposition de la doctrine de l'Église orthodoxe et des autres Églises chrétiennes* (1868).

**GUGGENBUHL, Louis**, a Swiss philanthropist, born in Zürich in 1816, died Feb. 2, 1863. He took his medical degree in 1836, and then spent three years in the study of cretinism at Seruf in the canton of Glarus. In 1842 he opened a retreat for cretins at Abendberg, above Interlaken. At first he encountered some opposition from the government in consequence of having substituted Protestants for the sisters of mercy who had been originally employed, but afterward had great success, and showed that the condition of many of the cretins is susceptible of improvement. The institution established by him was abandoned after his death. He published a treatise (Basel, 1851) and various pamphlets on cretinism.

**GUIANA, Guyana, or Guayana.** 1. An extensive territory on the N. E. coast of South America, comprising three distinct colonies, viz.: British, Dutch, and French Guiana. It lies between lat. 0° 55' and 8° 40' N., and lon. 51° 30' and 61° W., and is bounded N. by the Atlantic, E. and S. by Brazil, from which it is separated by the Oyapok river and the Tumucuraque and Acaray mountains, and W. by Brazil and the Venezuelan province of Guayana; area estimated at 195,000 sq. m.; pop. about 280,000. The coast line is about 740 m. long. The shore is skirted with mud banks, the water on which gradually decreases in depth toward the beach; which circumstance, added to the absence of landmarks, and the existence of rocks, bars of mud, and quicksands at the mouths of the rivers, renders the approach difficult for all craft, and impossible for vessels drawing more than 12 ft., these being obliged to moor 3 m. from shore. The level of the coast region, from lon. 54° to 61°, normally corresponding to that of the sea at high water, sinks at least one foot when the lands are drained and cultivated, so that the water can only be kept back by means of embankments and sluices. From lon. 54° eastward, the shore is not quite so low; but it is in some parts marshy, and is chiefly covered with mangrove forests. Beyond the flat country, which extends to a mean distance of 50 m. inland, except E. of lon. 54°, where it ends much nearer the sea, the surface gradually swells to an elevation of 200 ft., forming the northern edge of the table land of Guiana. This plateau, with a generally rising tendency, is intersected by parallel ranges of hills, much more numerous to the eastward, extending rib-like to the sierras of Tumucuraque and Acaray at the

extreme south, and limiting the basins of large rivers. The loftiest eminences, however, are in the west. Mt. Roraima, in the Socaraima range, forming for a distance of 18 m. part of the western limit of the country, is at once the highest in Guiana (7,500 ft.) and one of the most remarkable on the globe; it is a flat-topped solid mass, the upper portion of which presents a precipice 1,500 ft. high, glistening with the spray of numberless cascades which plunge down its sides. None of the other mountains attain a greater altitude than 4,000 ft. They are mostly of granite, and not a few isolated pyramidal or conical peaks shoot abruptly upward, and present with their denuded summits a striking contrast to the luxuriant vegetation at their base. The hills at the N. border of the table land are mostly of sandstone; and some of white quartz, with numerous particles of mica, glitter like gold. Throughout the whole flat country between the plateau and the sea a granite stratum underlies alluvial soil and clays, the last being covered with a black vegetable mould many feet deep, deposited by the rivers during their inundations. In the Essequibo is found a species of pure white clay.—The territory is drained by six large rivers. The Essequibo and the Berbice, in the western or British division, are both navigable by large vessels for 50 m. from the sea. The Corentyn separates the British from the Dutch possessions; and in the latter are the Saramaca and the Surinam, both of considerable magnitude. The Maroni forms the dividing line between Dutch and French Guiana. The Demerara, though comparatively small, is navigable for 100 m. up. All these rivers hold a generally northern course, through regions of great natural beauty, and receive the waters of numerous and extensive tributaries, especially the Essequibo, which has the Cuyuni and Masaruni (both little inferior to itself in magnitude), the Rupununi, Potaro, and others. The grand waterfall of Kaieteur is formed by the waters of the Potaro dashing in a single leap from the basin of that river into the valley of the Essequibo, a depth of 822 ft. The width of the river at the edge of the fall is 369 ft., and the depth of the water near the edge is 15 ft. in the dry season. Several smaller rivers fall into the Atlantic at various points. The climate, naturally hot in the low regions, is tempered by easterly breezes blowing steadily all the year round, the mean annual temperature being 80° F., and is much more salubrious than that of any of the West India islands, especially in the interior, where epidemics are almost unknown. In the rainy seasons, which embrace the months of December, January, February, June, July, and August, the rivers inundate the surrounding country, and intermittent fevers prevail. These seasons are ushered in by terrific thunderstorms, but hurricanes never occur. Slight shocks of earthquake are sometimes felt. The fertility of the soil is unsurpassed in South America, and ve-

getation is everywhere luxuriant. Fully one half of the territory is occupied by dense forests, whose majestic trees, supporting numberless convolvuli and other parasitic plants of endlessly varying hues, afford excellent timber prized for its hardness and durability, and inexhaustible quantities of fancy woods. The hard-wood species include varieties of *mimosa*s, such as the bully tree, often growing to a height of 100 ft., with a trunk 6 ft. in diameter, destitute of branches for the first 60 or 70 ft.; the greenheart (*nectandra Rodiei*), whose ash-colored bark is efficacious as a febrifuge; the crabwood (*carapa Guianensis*), sirwabali, sawari, purpleheart (*copaifera pubiflora*, and *C. bracteata*), and the mira tree (*mimosa excelsa*), attaining a height of 150 ft., whose wood is reputed as not inferior to teak. Chief among the precious woods is the mahogany, and among the palms the *areca oleracea* or cabbage palm. The *Bertholletia excelsa*, or Brazil-nut tree, constitutes in some parts whole forests; and almost all the intertropical fruit trees are found in abundance. Of woods and plants used for dyeing, there are several varieties; medicinal plants are common; and there are numerous fibrous plants furnishing a substitute for flax. The wild flowers are of indescribable splendor, including the gorgeous *Victoria regia*. One fourth of the country is devoted to plantations, where maize, cassava, yams, sweet potatoes, and arrowroot are cultivated to a considerable extent. The soil is well adapted to sugar, coffee, and cotton; and tobacco and indigo are likewise produced. The remaining fourth of the territory comprises meadow plains, affording excellent pasture to numerous herds of cattle and horses. The hilly regions are frequented by cougars and jaguars; the tapir is the largest quadruped; ant-eaters, armadillos, and agoutis are common; there are two or three varieties of deer; and the forests are inhabited by hosts of monkeys of many kinds. Vampire bats are numerous; the boa constrictor and anaconda or *tragavados* abound along the banks of the rivers; and all the South American varieties of venomous snakes are here represented. There are several sorts of lizards, and the iguana is eaten as a delicacy by the natives. The marshy districts, and the flat country generally, after the rains have subsided, are infested by myriads of insects capable of inflicting troublesome if not dangerous wounds. The rivers swarm with alligators, sharks, and *peris* or *omas*, 2 ft. long, and armed with strong and formidable teeth; and they also afford excellent edible fish, such as the silurus, often measuring 12 ft. and weighing upward of 200 lbs. In most of the large rivers there are electric eels, turtles, and manatees or sea cows of gigantic size, but differing in most respects from the manatee of the West Indies. Among the birds are flamingoes, toucans, pelicans, spoonbills, peacocks, and Muscovy ducks; macaws, parrots, and other birds of brilliant plumage, including the humming

bird.—The population is made up of English, Dutch, French, and other Europeans, negroes and mulattoes, descended from the slaves formerly imported from Africa, and Indians, including the remnants of half a dozen tribes. The Warrows dwell in the vicinity of the plantations, where they sometimes work for wages; the Arrawaks inhabit the coast, and are skilled in boat building; but they are intemperate, improvident, and filthy. The other tribes live far from the European settlements; many of them are of a remarkably fair complexion. A few still practise cannibalism, but with these are not to be confounded the small number of Caribs to be met with in the same region, and who, like all the continental Caribs, have never been addicted to eating human flesh.—Guiana, discovered by Columbus in 1498, was visited by Vicente Pinzon two years later. Diego de Ordaz founded in 1531 the first town, St. Thomas; Dutch settlements were established about 1580; and in 1595 Sir Walter Raleigh landed in the country with the intention of exploring it in search of gold, a project which he did not execute till 1617. African slaves were first introduced in 1621. **II. British Guiana**, sometimes called DEMERARA, the largest of the three colonies comprised in the preceding territory, lies between lat. 0° 55' and 8° 40' N., and lon. 56° 20' and 61° W., and is bounded N. by the Atlantic, E. by Dutch Guiana, from which it is separated by the river Corentyn, S. by Brazil, and W. by Brazil and the Venezuelan prov-

ince of Guayana; area, 99,925 sq. m.; pop. in 1871, 193,491. In 1851 the population was about 130,000, and by the end of 1861 no fewer than 80,000 immigrants had been received, consisting of Europeans, free negroes, and East Indian and Chinese coolies. The census of that year gave 148,026 as the total population, 79,644 of whom were males. The immigration, though costly (agents having been sent to Calcutta and Canton to promote it), has been successful. (See COOLY.) The number of indentured laborers in June, 1866, was 32,124, and 3,069 not indentured, 8,739 of the whole being females. Some invest their money in the purchase of land, the price being fixed by law at \$10 per acre. Licenses for cutting timber, large quantities of which are exported, can be obtained for from 300 to 1,000 acres, at 1s. 3d. per acre. The country was formerly divided into the three counties of Essequibo, Demerara, and Berbice, but the two first are now united. The chief towns are Georgetown, at the mouth of the Demerara river, the capital of the colony, Demerara, and New Amsterdam or Berbice. The staple products are coffee (the cultivation of which has diminished of late years), tobacco, indigo, maize, rice, sugar cane, fruits of various sorts, vegetables, &c. Wheat does not thrive. The principal exports are sugar, rum, molasses, cacao, cotton, timber, dye woods, and dye stuffs. The total exports to Great Britain in the five years from 1868 to 1872 inclusive were as follows:

ARTICLES.	1868.	1869.	1870.	1871.	1872.
Rum .....	\$1,645,760	\$1,220,880	\$1,696,740	\$1,636,285	\$1,306,545
Sugar .....	6,008,745	4,405,500	5,408,250	5,064,800	5,287,810
Cacao .....	8,425	9,650	17,960	35,390	20,880
Molasses .....	101,785	108,910	22,800	82,530	25,190
Wood .....	882,750	149,110	70,000	40,005	43,695
Cotton .....	72,765	77,880	42,980	7,485	37,330
Sundries (dye stuffs, &c.) .....	56,005	75,560	93,620	73,760	88,985
Total .....	\$8,226,285	\$6,044,940	\$7,351,750	\$6,890,025	\$6,814,885

The imports from the same country in the same period were:

YEARS.	Value.	YEARS.	Value.
1868 .....	\$3,355,520	1871 .....	\$3,957,790
1869 .....	8,271,535	1872 .....	4,450,760
1870 .....	4,233,190		
Total .....			\$19,248,795

The total exports for the year 1871 amounted to \$13,745,000, and the total imports to \$9,485,000. The internal communication is carried on by boats upon the rivers. In 1871 441 vessels entered and cleared. The finances of the colony in the same year were as follows:

Income .....	\$1,950,000
Expenditure .....	1,690,000
Surplus .....	\$260,000

The public debt was \$2,565,000. The government consists of a court of policy, of ten members, five of whom are official, the governor, chief justice, attorney general, collector of cus-

oms, and government secretary, and five non-official. There were 101 public schools in 1863 receiving public aid, and attended by 8,251 scholars; and the whole number of children receiving instruction in the colony was 12,425. In 1866 the schools numbered 118, with an average attendance of 6,615 pupils.—British Guiana was discovered by Vicente Pinzon in the spring of 1500, and the Dutch formed the settlements of New Amsterdam, Demerara, and Essequibo about 1580. The English, who settled in the neighborhood of New Amsterdam in 1634, withdrew in 1667. The colonies were attacked by the French in 1690 and in 1712, and a contribution levied on each occasion. A negro insurrection took place in 1762. The colonies were occupied by the English, under Gen. Whyte, in 1796, but were restored to the Dutch in 1802. They were retaken in 1803, and by an agreement between England and the Netherlands, concluded in 1814, retained by the former country. In 1831 they

were formed into one colony, under the name of British Guiana. Slavery was abolished in 1834, and the system of apprenticeship was abandoned in 1838. In 1827 the territory was included in the bishopric of Barbadoes and the Leeward Isles; but in 1838 it became an archdeaconry, and in 1842 was erected into a separate bishopric. **III. Dutch Guiana, or Surinam**, extends from the Corentyn to the river Maroni, lying between lat.  $1^{\circ} 20'$  and  $6^{\circ}$  N., and lon.  $53^{\circ} 15'$  and  $57^{\circ} 45'$  W. It is bounded N. by the Atlantic, E. by French Guiana, S. by Brazil, and W. by British Guiana; area, 55,785 sq. m.; pop. in 1871, 59,860, including 650 soldiers, 400 marines, 1,000 Indians, and 7,500 maroons or fugitive African slaves and their descendants, who live chiefly in the hill country. Paramaribo, on the bank and about 10 m. from the mouth of the Surinam river, is the capital; the governor's residence is at Zeelandia, a short distance N. of that city. Since the importation of slaves ceased, the population has gradually diminished; in 1852 it was 64,270. The country is flat and swampy near the coast, mountainous in the interior, and watered by numerous rivers. The products are the same as in British Guiana. The exports, principally cacao, sugar, rum, cotton, indigo, and other dyes and dye woods, are far from being as extensive now as when slavery existed. The total value of the exports to Great Britain in 1868 was \$406,980; 1869, \$369,650; 1870, \$544,420; 1871, \$823,295; 1872, \$874,890; of the imports in 1868, \$177,015; 1869, \$184,845; 1870, \$235,505; 1871, \$192,965; 1872, \$213,700. Surinam is an expensive colony to the Netherlands, as may be seen by the state of the finances in 1872, viz.: revenue, \$79,944 80; expenditure, \$480,274 40; deficit, \$300,329 60. The government is vested in a governor general and council.—Dutch Guiana was visited by the French in 1640. It was taken by the English in 1650, and granted by charter of Charles II. to Lord Willoughby in 1662. The Dutch took possession of it in 1667; the English retook it shortly afterward, but ceded it back to the Dutch in 1669. By the peace of Westminster it was allotted to the Dutch in exchange for the province of New York. It was again taken by the English in 1796, restored in 1802, recaptured in 1804, and again given up to Holland in 1814. **IV. French Guiana, or Cayenne**, lies between lat.  $1^{\circ} 15'$  and  $5^{\circ} 45'$  N., and lon.  $51^{\circ} 30'$  and  $54^{\circ} 35'$  W. It is bounded N. by the Atlantic, E. and S. by Brazil, and W. by Dutch Guiana; area, 40,140 sq. m.; pop. in 1868, 25,151. The territory includes the island of Cayenne (see CAYENNE), and is divided into the two districts of Cayenne and Sinnamary, and subdivided into 14 communes or arrondissements. The country near the coast is flat, marshy in some parts, and in others covered with forests of mangroves. The climate is much hotter and more unhealthy than in the other divisions of Guiana. The products of the other two col-

onies are likewise found here, with the addition of pepper (especially the kind bearing the name cayenne), cloves, cinnamon, nutmeg, &c. The state of agriculture is very low. The total exports in 1864 amounted to \$265,475, and the imports to \$1,956,765. The governor has a privy council, with a colonial council of 16 members elected by the colonists.—The country was settled by the French in 1604, and again in 1635. The English seized the colony in 1654, and held it till 1664. The Dutch took it in 1676, but were obliged to restore it to the French in 1677. It was again taken by the British in 1809, and finally restored to France at the peace of Paris in 1814.

**GUICCIARDINI, Francesco**, an Italian historian, born in Florence, March 6, 1482, died near that city in May, 1540. At the age of 23 he held a professorship of law, and was afterward appointed ambassador to Ferdinand the Catholic. He was soon called to the court of Leo X., who made him governor of Modena and Reggio, which dignity he retained under Adrian VI. Clement VII. sent him to the Romagna, where he succeeded in quelling the conflicts of the Guelphs and Ghibellines. As lieutenant general of the pope he defended Parma against the enemy, and subdued the revolted city of Bologna, after which he retired (1534) to Florence and commenced his history. On the assassination of Alessandro de' Medici, he exerted himself to defeat the project of the senate for restoring the republic. Cosmo de' Medici was made governor by his influence, but soon exchanged this title for that of duke, and assumed absolute power in the state, when Guicciardini, who had been attached to him, resigned his office and retired. Of his "History of Italy," the first complete 16 books appeared in 1561, edited by his nephew. A few years afterward four more were added, but these are not complete. It has since been often reprinted in 20 vols., but the best edition is that by Rosini (10 vols., Pisa, 1819-'20). Among the other remains of Guicciardini are *Consigli aurei ed avvertimenti politici* (translated into French, Paris, 1577), and parts of his correspondence published by Bernigio under the title *Considerazioni civili sopra l'istoria di Francesco Guicciardini* (Venice, 1582), and under that of *Legazione di Spagna* (Pisa, 1825).

**GUICCIOLI, Teresa**, countess, born about 1802, died in Rome, March 26, 1873. See BYRON.

**GUICOWAR, or Guikwar, Dominion of the, or Baroda**, a tributary state of British India, in the division of Guzerat, province of Bombay. The former dominions of the Guicowar comprised about 29,400 sq. m., lying around the gulf of Cutch, between lat.  $20^{\circ} 40'$  and  $24^{\circ}$  N., and lon.  $69^{\circ}$  and  $74^{\circ}$  E. The present Baroda, which is all that remains under the nominal rule of the native prince, has an area of 4,400 sq. m.; pop. about 350,000. (See BARODA.) For its physical characteristics, see GUZERAT.

**GUIDI, Tommaso**. See MASACCIO.

**GUIDO ARETINO**. See ARETINO.

**GUIDO RENI**, an Italian painter, of the Bolognese school, born near Bologna in 1575, died there in 1642. He studied under Denys Calvaert and Ludovico Carracci, and went to Rome, where his "Martyrdom of St. Cecilia" was very successful. He received an order from the pope to decorate the private chapel of the palace of Monte Cavallo, but became disgusted with the parsimony of the papal treasurer and returned to Bologna, where he painted the "Massacre of the Innocents." Recalled by the pope to Rome, he executed a number of important works, including his frescoes of the "Aurora" in the Rospigliosi palace, the "Concert of Angels" in the apsis of the Capella Sta. Silvia, the "St. Andrew" in the chapel of that name, and the painting of "Fortune" in the gallery of the capitol. He was invited to Naples, and had nearly finished the "Nativity," now in the choir of San Martino, when he was driven away by the jealousy of the Neapolitan artists. The remainder of his life was passed at Bologna. At this period he gave himself up to play, and painted rapidly and carelessly. Many of his later works are unfinished, and some which bear his name are by his pupils. The best of this period are his "Assumption," in the gallery at Munich, and the Madonna with angels, now in Bologna.

**GUIENNE**, an ancient province in S. W. France, a part of the old kingdom of Aquitaine, bounded N. by Saintonge, Angoumois, Limousin, and Auvergne, E. by Languedoc, S. by Languedoc and Gascony, and W. by the bay of Biscay. In 1152 the duchy passed to Henry Plantagenet (afterward Henry II. of England) through his marriage with Eleanor, niece of William X. of Aquitaine. The kings of England maintained their possession of it with some interruption till 1451, when it was conquered by the army of Charles VII., under Dunois. Out of the territory of Guienne the departments of Gironde, Lot, Lot-et-Garonne, Dordogne, Aveyron, and part of those of Landes and Tarn-et-Garonne, have been formed.

**GUIGNES.** **I. Joseph de**, a French orientalist, born in Pontoise, Oct. 19, 1721, died in Paris in March, 1800. When only 20 years old he was an extraordinary sinologue. In 1752 the royal society of London elected him a member, and in 1754 the French academy of inscriptions did the same. His principal work was *Histoire générale des Huns, des Turcs, des Mongols et des autres Tartares occidentaux, avant et depuis J. C. jusqu'à présent* (5 vols. 4to, 1756-'8). He was appointed in 1757 professor of Syriac in the collège de France, and in 1769 keeper of the antiquities in the Louvre. He wrote several essays and papers, among which was a curious *mémoire* in which he contends that the Chinese are but an Egyptian colony.

**II. Chrétien Louis Joseph**, son of the preceding, born in Paris, Aug. 25, 1759, died March 9, 1845. For 17 years he was French resident and consul at Canton. He published, besides several other papers, *Voyages à Péking, Manille*

*et l'Île de France* (3 vols. 4to, 1808), and edited under his own name in 1813 a *Dictionnaire chinois, français et latin*, which was really only the *Hun-tsé-sy-y* of Basilius de Glemona revised and enlarged.

**GUILD**, or **Gild** (Sax. *gildan*, to pay), a name given in England and France to societies organized for mutual aid and protection, as well as to confraternities whose chief object is piety or beneficence. The denomination of confraternity (*confrérie*) was formerly bestowed in France on lay brotherhoods united for secular as well as for religious purposes; it is now restricted to pious and charitable organizations. Before the reformation the term guild was used in England indifferently for both, and it is often so applied at present. **I. SECULAR GUILDS.** Societies of artisans were organized in Rome at a very early period, and, together with merchants' corporations, continued to increase in numbers and importance until the fall of the republic. Their turbulence caused them to be suppressed in the consulship of L. Cæcilius and J. Martius; but they were restored by Clodius. Incorporated with fixed statutes under the last Cæsars, they spread all over the empire. The Christian religion found them among the laboring classes in the East and West, infused into them its active spirit of brotherly charity, and thus the old pagan corporation (*collegium*) became the Christian guild. In 364 Valentinian I. confirmed the privileges granted by preceding emperors to the trades' corporations, and about this epoch each trade became a separate guild, whose members, as well as their offspring, could embrace no other calling. As a compensation, the guilds were empowered to accept donations and legacies, and to inherit the property of intestate members. They were also bound to provide for the requirements of the public service, and in return obtained in many instances most lucrative monopolies. Throughout the West these societies are called by early Christian writers *collegia opificum*, companies of craftsmen. In Piedmont some charters of guilds date from the year 707. The records of Ravenna mention a guild of fishermen in 943, one of merchants in 953, and "a provost of the guild of butchers in 1001." In southern Gaul the municipalities from time immemorial had their confraternities of tradesmen, forming the great body of free citizens, and their consuls, as the chief magistrates were called. Nor was it otherwise in northern Gaul, when the invasion of the Franks came to disturb the social growth of centuries. The annals of the Merovingian kings mention a college or guild of jewellers or workers in gold and silver; and the edicts of Dagobert designate a guild of bakers. In 1061 Philip I. granted privileges to the master chandlers. Louis VII. in 1162 speaks of "the ancient customs of the guild of butchers," and granted to the widow of one Ives Laccobre and her heirs the right of collecting the moneys due to the royal treasury by the guilds of leather dressers,

shoe and harness makers, &c. The most ancient of chartered French guilds is the *hanse* of merchants and watermen of the Seine, which is supposed to have sprung from the Parisian "nautes" (Lat. *nauta*, sailors or boatmen) existing in the time of the Romans. This body had absolute control of the trade carried on by the watercourses of the Seine and the Yonne between Mantes and Auxerre; no merchant could bring his wares into Paris without becoming a member of this guild or obtaining from it *lettres de hanse*. Similar guilds sprang up in most of the commercial cities situated along the other river courses or on the seashore. Sometimes several of these formed a commercial league, such as existed between the Hanseatic towns of Germany. Above the trades were several privileged guilds, such as the merchants' guilds called *les six corps*, viz.: drapers, grocers, haberdashers, furriers, hatters, and jewellers.—According to Sismondi, the cities of Flanders and Holland secured the benefit of self-government before those of France or Italy; and Thierry deduces this fact from the institution of guilds or fraternities among the burghers. Two essential characteristics belonged to them, the common banquet and the common purse. In many instances they had a religious, and in some a secret ceremonial, to knit more firmly the bond of fidelity. From the private guild, possessing the vital spirit of faithfulness and brotherly love, sprang the sworn community, the body of citizens, bound by a voluntary but perpetual obligation to guard each other's rights against the thefts of the weak or the tyranny of the powerful. The progress from the guild to the corporation can be traced in other European countries; but in the Low Countries from time immemorial they are found to co-exist. All through the middle ages the Dutch and Flemish guilds exercised a preponderating influence. There is not a cathedral or church edifice of any importance in Holland or Belgium but contains some pictorial or sculptured monument commemorative of some great event connected with these guilds, and representing their costumes, banners, corporate seal, or public festivities. In Paul Lacroix's *Mœurs, usages et costumes au moyen âge*, are engravings of various trades' guilds of St. Trond, Hasselt, Bruges, Maestricht, Antwerp, and Ghent.—In Germany the immunities and privileges enjoyed under the Roman domination by the brotherhoods of craftsmen were swept away by feudalism; the condition of the workmen was one of serfage down to the time of the emperor Henry I. (919-'36). During the next two centuries the guilds banded themselves together, and gradually acquired such power in the cities that they rivalled the nobles in influence and aimed at controlling the municipal government. Charlemagne had felt their power, and in his capitularies laid down rules limiting the growth of guilds in conformity with local needs. The emperors Frederick II. and Henry

VII. vainly attempted long afterward to suppress the guilds, whose incessant contests with the nobility led to frequent bloodshed.—The whole laboring population of England during the Anglo-Saxon period was virtually organized into guilds. The charters of many English guilds date from the 10th century; the steelyard merchants (*gilda Theutonicorum*) existed before 967, and were chartered in 1232; the establishment of the saddlers' company dates from the same epoch. Trade guilds are mentioned in the *Judicia Civitatis Londoniæ*, compiled by King Athelstan, and in other Anglo-Saxon laws; they must therefore have existed in 939. But it is certain that others existed before that; lawyers agree that the stallingers of Sunderland, the dredgers of Whitstable, and the free fishermen of Faversham have existed from time immemorial. Another famous brotherhood was the *cnihten* or knighten guild, which existed in the reign of Edgar (died in 975), and was chartered by Edward the Confessor (1042-'66). All this confirms the assertion of Lingard, that at the Norman conquest there were guilds not only in the chief cities of England, but in the surrounding rural districts, all organized on the same principles. The boroughs were made up of guilds of tradesmen, who had conquered their freedom by their union; and in each borough these guilds formed one body politic with common rights and common interests. They had each their hall or hanse house, in which they met and deliberated; they exercised the power of enacting by (or borough) laws; and they possessed, by lease or purchase, houses, pasture, and forest lands for the common use. Under Norman rule, the growth of guilds was much interfered with at first. Henry I. (1100-'35) commanded that all should receive the royal license; and he subjected several guilds, secular and religious, to heavy fines, because they had been established without license, or exercised their functions independently of it. This penalty fell heavily on London, where the religious guilds or confraternities were very numerous. They were much encouraged by Henry II.; but as they increased under this patronage, and were much given to parading with their respective "liveries" and banners, collisions between rival trades became so frequent that at length under Henry IV. they were forbidden to wear their liveries. In subsequent reigns they were permitted to appear in them at coronations, and finally it became necessary to obtain the royal license for appearing in public with their insignia. The term "livery company" was substituted for that of guild in the reign of Edward III. (1327-'77), and has been applied ever since to the London trades in particular. The most ancient of these is believed to be the guild of woollen weavers (*gilda telariorum*), chartered by Henry I. In Stow's time there were in London 63 livery companies, 12 of which are called by him "honorable companies out of which the lord mayor

is to be chosen yearly." At the present day there are 89 such guilds in London, 39 of which have halls of their own, the others meeting in Guildhall or in certain taverns. The freemen or liverymen of "the city" elect two candidates for the mayoralty, one of whom is chosen by the court of aldermen; the liverymen also elect the sheriffs and chamberlain. Many relics exist in other English cities to attest the importance of guilds in the middle ages. Once in 20 years, toward the end of August, Preston celebrates "guild day" by a solemn procession, in which the corporation and all the local guilds take part. Throughout Norfolk, in Norwich, Aylesham, Lynn, and Worstead, survive memories of the numerous and powerful guilds of woollen workers (carders, spinners, weavers, fullers, shearers, &c.), who contributed so much in their day to the commercial prosperity of England.—In Great Britain, in spite of the severe control exercised by the crown, the establishment of guilds and the exercise of independent trade were not subjected to the tyrannical restraints which existed on the continent. All trades were equal in England; every individual was free to choose the craft to which he wished to belong; and the road to apprenticeship and mastership was equally open to all. Besides, as membership in an English borough soon came to be coupled with the right of suffrage, numbers of men who did not belong to the craft sought to obtain the freedom of the guild. But the common law, the watchful jealousy of the civil courts, and the spirit of the nation did not allow these organizations to cover the land with their network as they did in France and Germany. Beyond the limits of the boroughs, which were the centres of the great industrial guilds, labor and trade flourished in freedom over a wide domain. Still, ever since the time of Edward I., they had their distinctive liveries and banners, lived ordinarily in the same street, and not unfrequently occupied an entire ward or quarter, and were, in fact, so many close corporations. Many of the guilds in England and Scotland maintained up to a recent date their characteristic exclusiveness; no person who was not free of the borough or of certain of these guilds was permitted to open a shop for merchandise, or exercise certain trades within the borough. These restrictions were abolished in 1835; and their place has since to a large extent been taken by the trades' unions.—In France the guilds were under the immediate control of the high officers of the crown. Thus the high chamberlain governed all the trades which bore a relation to his office, such as clothiers, upholsterers, &c.; the master of the horse was head of the farriers, &c.; and so with the other officials. They disposed of the masterships in each trade, delivered patents, and collected the heavy fees attendant on mastership. This authority was delegated to lieutenants, who had a superintendence of their re-

spective trades throughout the kingdom, and were called "kings of guild." They maintained in the 14th century a courtly retinue of subordinates at the expense of the tradesmen, decided all civil and criminal questions among their subjects, visited merchants' and tradesmen's houses and workshops to discover frauds, imposed fines, levied taxes, and exacted pleasure money for their own use. Between the kings of guilds themselves arose frequent conflicts of jurisdiction, in which rival pretensions were sustained by armed force; while the provosts of the various cities strenuously resisted all exercise of authority over the guilds by these officials as a usurpation of their own. The tradesmen were invariably called upon to support these conflicting claims, which led to continual riots and bloodshed. However, the authority of the provosts prevailed in the end, because their interests were identified with those of the workmen. Each craft or "mystery" had, besides the officers thus imposed upon it by the crown, its own chosen chiefs, designated as masters, deans, wardens, syndics, &c. It was the duty of these to visit at all hours the workshops of members of the guild and their salesrooms, to enforce the strict rules of the craft, and to examine candidates for apprenticeship and mastership. In France the exclusive *esprit de corps* permitted but few to find admittance into a craft. The children of a master workman were alone free from the usual restrictions. Each trade was divided into three classes, masters, companions, and apprentices. Apprenticeship began between the ages of 12 and 17, and lasted from 2 to 10 years. In most trades a master was allowed only a single apprentice besides his son. Tanners, printers in color, and jewellers might have a second apprentice, provided he were, if possible, a kinsman. Butchers and bakers were permitted to have any number of apprentices they required. Candidates for a mastership underwent a most trying ordeal. They had to work alone, under the supervision of the syndics or judges, in order to produce a "masterpiece," or faultless piece of handicraft, besides fabricating all the tools and machinery in use in the craft. A mastership was only recognized within the borough limits. No work was to be done by night, because the trade required all workmanship to be thoroughly good. Morality and concord were secured by stringent regulations. Illegitimate children could never become apprentices; and a stainless reputation was also necessary. Known immorality or irregularity of conduct was sufficient cause of expulsion from the guild. Each guild had its patron saint. Crispin and Crispinian were the patrons of shoemakers, and St. Joseph of carpenters. The patron saint had a special chapel dedicated to him in the nearest parish church or cathedral; it was furnished and decorated by the guild, and served for all ceremonies in which the craftsmen were interested. The guilds aided sick members, and

took care of the families of deceased members. At a later period a union of kindred guilds enabled workmen to get employment in any city.—Among the guilds of the middle ages which exercised a widespread influence, were the brotherhoods of artisans (masons, carpenters, workers in bronze and iron, painters of stained glass, &c.), who were employed on public constructions. Even before the appearance of the ogival or Gothic style of architecture, the erection of the beautiful round-arched cathedrals and municipal edifices of eastern and western Europe had employed hosts of craftsmen and artists. Their guilds had been everywhere special objects of favor from the civil and ecclesiastical authorities; the popes themselves bestowing on them the most coveted franchises and immunities. They were taken under the pontifical protection and declared free from the burdens which weighed on the masses, and from which the other trades and professions were not exempt. They were in consequence denominated “free.”—Guilds were not limited to merchants, mechanics, and laborers; the liberal arts and the higher professions had also kindred organizations. In France the “order of advocates” has been, from the 14th century at least, a guild with its head in Paris and branches in all the cities. The distinction between the judicial body and the bar (*la magistrature et le barreau*) became at an early date quite marked, one profession excluding the other, although both were inseparable coördinates in the administration of justice. St. Louis in his *Établissements* has several statutory enactments concerning the body of advocates or *avantparliers*. The edicts of 1274 and 1291, issued by his successors, regulate the maximum fee to be paid an advocate in each case. In 1315 the advocates of Toulouse gave, as a body, a large sum toward the expenses of the war in Flanders. An order of the parliament of Paris in 1344 prescribes that no lawyer shall be heard in court whose name is not inscribed on the roll of advocates (*rotulus nominum advocatorum*); and a royal edict of 1364 commands all advocates to plead gratuitously the cause of the poor. In every city where there was a parliament they had their dean or *bâtonnier*, elected by themselves, and a council which judged of the qualifications for membership. The applicant must be a graduate, licentiate, or doctor in laws, and after his admission pass three years as a *stagiaire*; the council then decided whether his name should be placed on the roll. When this had been done, the advocate had the right of pleading in any court of the land where his services were asked for. The profession was incompatible with any salaried function, commercial pursuit, or labor for wages, as well as with the position of notary, *avoué*, or clerk; but not with any dignity that was purely honorific. The amount of their fees was left to the generosity of the client; any attempt to exact them or sue for them entailed

expulsion from the order. These qualifications and privileges are substantially true of the order in its present state. It was suppressed in 1790, and reestablished with many limitations in 1810, but was not looked upon with favor by Napoleon I. Connected with the “order of advocates” in France was *la basoche*, or guild of lawyers’ apprentices (from Lat. *basilica*, a court of law, and old Fr. *baseuque* and *basoque*) of the parliament of Paris. This guild was authorized by Philip the Fair in 1303. It preserved throughout its existence the character of an essentially lay organization. The title of kingdom (*royaume de la basoche*) was bestowed upon it from its infancy, and its chief was authorized by royal edict to assume the title of king, to wear the robes of royalty, and to surround himself with high officers named after those of the crown, and vested within the brotherhood with supreme civil and criminal jurisdiction. The king of this guild had his own great seal, kept by his high chancellor; coined money of gold and silver, which was a legal currency in all transactions between members of the guild and all who trafficked with them; and had his army, consisting of the members mounted and equipped. This army sometimes paraded as many as 10,000 cavaliers arrayed in blue and yellow; it furnished a cavalry corps of 6,000 members to Henry II. in 1548, which aided effectively in quelling the revolt in Guienne. Their charter obliged them to parade annually; and the pageant never failed to draw immense crowds to Paris, all the more so as they soon added to the military spectacle dramatic representations, in which the vices of all classes in church and state were held up to merciless ridicule. This custom and their numbers so alarmed the cruel and superstitious Henry III. that he suppressed the office and title of king of *la basoche*, and forbade their parades and representations. Thus deprived of their prestige, they maintained their organization down to the end of the last century, and furnished an armed battalion at the commencement of the French revolution, which figured prominently on several occasions, appearing for the last time at the assault on the Bastille. The *basochiens* were suppressed with all other corporations in 1791. Besides the above organization among the clerks of the Parisian parliament, the *châtelet* and the *cour des comptes* had their *basoches*. The provincial parliaments organized guilds similar to that of the capital, and vying with it in influence, turbulence, literary activity, and joyousness of spirit.—The members of the Scottish bar form a guild, with the title of faculty of advocates, which has existed from immemorial custom, with constitutional privileges founded on no statute or charter. The body formed itself gradually from time to time on the model of the French guilds of advocates, appointing like them a dean, who is their presiding officer.—A “guild of literature and art” was originated in 1851 by Charles Dick-

ens and Lord Lytton, for the relief of indigent men of letters and artists. A fund was created by a distinguished party of amateurs, who gave representations of the comedy "Not so Bad as we Seem;" and three buildings were erected near Stevenage in Hertfordshire, on ground given by Lord Lytton, and inaugurated July 29, 1865. II. RELIGIOUS GUILDS, also called confraternities or sodalities (Lat. *sodalitas*, companion), have always been numerous and popular in Roman Catholic countries. Some of them, like the confraternity of bridge builders (*fratres pontifices*), were closely allied to the guilds of carpenters and masons, devoting themselves in the 13th century to opening and repairing roads, building bridges, maintaining cheap or gratuitous hostleries, and watching over the safety of travellers. Kindred to these were the confraternities established during and after the crusades, to prevent wars between the feudal lords, to protect widows and orphans from oppression, to guard churches and monasteries from violence, and repress the bands of roving mercenaries (*rouitiers*) who infested the highways of Europe. Such were the confraternity of "the truce of God," the *confrérie de Dieu* in Normandy, the "militia of Christ" in northern Italy, and even the *Vehmgerichte* of Westphalia. These confraternities, much as they may have been perverted from their original purpose, sprang from motives of religion and beneficence. The confraternities devoted to works of pure charity were innumerable. In Rome before the late change of government upward of 200 such guilds were in activity; and the other cities of Italy were little inferior in this respect. Paris, after Rome, counted the largest number of confraternities, prominent among which are the sodality of St. Vincent de Paul, known throughout the United States, and the societies of St. Francis Xavier and St. Francis Régis, which aim at doing away with concubinage among the laboring classes, &c. The *confrérie de la passion*, organized for the purpose of representing on Sundays and holidays the mysteries of Christ's passion and other Biblical subjects, was originally a lay brotherhood attending on the sick in the hospital of La Trinité in Paris. The entertainments which they instituted for the convalescents in one of the wards soon became so popular that the king gave them a monopoly of all such plays. In 1543 they opened a *salle de spectacle* in the rue de Mauconseil, which became the cradle of French comedy. But as the edict which renewed their charter of monopoly forbade pagan plays and other than sacred dramas, they renounced profane theatricals as inconsistent with their religious garb, and made over their privilege to another company. Religious guilds have recently much increased in England, as well among Roman Catholics as among those called ritualists in the church of England and in the Protestant Episcopal church in the United States. A list of the latter is given in the "Church Union Almanac" for

1869. In the United States and British North America confraternities are both numerous and flourishing; temperance and mutual benevolent societies among Roman Catholics generally take this form, having prescribed religious practices, a patron saint, and stated feast days.

**GUILDFORD**, a municipal and parliamentary borough, market town, and the capital of Surrey, England, on the right bank of the Wey, 29 m. S. W. of London, at the junction of a branch of the Southwestern with the Guildford and Reigate railway; pop. in 1871, 9,801. The town stands on a declivity sloping toward the river, which is here crossed by a handsome bridge. There are three parish churches, a hospital, a theatre, barracks, several schools, and the Guildford institute, with library and reading room. The chief manufactures are paper, powder, bricks, coaches, iron, and malt liquors; the trade is mostly in timber, grain, malt, and live stock. In 1036, under the reign of Harold I., Alfred, son of Ethelred II., after landing in Kent with the design of recovering the kingdom, was induced to enter Guildford, where he was made prisoner in the night, and his 600 Norman attendants were massacred.

**GUILFORD**, a N. W. county of North Carolina, drained by Deep river, a branch of the Cape Fear, and by Reedy fork of Haw river; area, 600 sq. m.; pop. in 1870, 21,736, of whom 6,080 were colored. The surface is undulating and abundantly timbered; the soil is fertile, well watered, and highly cultivated; and there is a copper mine. It is traversed by the Richmond, Danville, and Piedmont, and the North Carolina railroads. The chief productions in 1870 were 132,783 bushels of wheat, 308,847 of Indian corn, 169,847 of oats, 22,521 of Irish and 23,468 of sweet potatoes, 149,490 lbs. of butter, 31,461 of wool, 177,782 of tobacco, and 5,761 tons of hay. There were 2,790 horses, 4,791 milch cows, 6,859 other cattle, and 13,302 sheep; 1 cotton factory, 18 flour mills, 10 tanneries, 8 currying establishments, and 1 manufactory of wagon material. Capital, Greensborough.

**GUILFORD**, a town and village of New Haven co., Connecticut, on Long Island sound, and on the Shore Line division of the New York, New Haven, and Hartford railroad, 15 m. E. of New Haven; pop. in 1870, 2,576. The village has an antiquated appearance, but contains a few handsome buildings, the chief of which is a high-school building of stone. In the centre is a public square, on which front the hotel, the principal stores, and four churches. There are few manufactures, the inhabitants being engaged chiefly in farming and maritime pursuits. The harbor is visited by fishing and coasting vessels. About 1 m. S. of the village is the Point, a favorite watering and bathing place; and 3 m. S. W. is the watering place called Sachem's Head. Guilford is the birthplace of Fitz-Greene Halleck, and here he spent the last years of his life. Here also the regicides Goffe and Whalley were for a time secreted. The

first settlement in the town was made by a party of English nonconformists in 1639, and the residence of their leader, the Rev. Henry Whitfield, called "the old stone house," is still standing, near the railroad station.

**GUILFORD COURT HOUSE**, a locality about 5 m. from Greensborough, Guilford co., N. C., memorable for a battle fought, March 15, 1781, between the Americans under Gen. Greene and the British under Lord Cornwallis. The American force numbered 4,243 foot and 161 horse, about 1,500 being regular troops, and the rest mainly raw militia. The British were about 2,400 strong, and consisted chiefly of veteran soldiers. Greene had chosen a strong position on the declivity of a hill, and drew up his army in three lines. The battle began shortly after 1 o'clock with a brisk cannonade on both sides, during which the British advanced upon the North Carolina militia, posted across the road, who after a discharge of musketry threw away their arms and accoutrements and fled through the woods. The Virginians of the second line, however, who were in a wood 300 yards in their rear, poured a galling fire upon the advancing troops; but their right finally retreated before the bayonet and fell back to the court house, and the left soon followed their example. The whole British infantry was now engaged, while the flower of the American army was still in reserve. The British pressed forward to the third line, composed of regulars under Huger and Williams, posted near the court house. The first regiment of Maryland continentals received them with a well directed fire, and before they recovered from the shock routed them with the bayonet. The second regiment of Marylanders, however, fled at the first onset, leaving two field pieces in the hands of the enemy; but the pursuers were repulsed by the victorious first regiment, and driven back in confusion by Lieut. Cols. Howard and Washington. To check the pursuit, Cornwallis ordered his artillery to play upon the Americans. The expedition was successful, but he was forced to fire full in the face of his retreating guards, and only half the battalion was extricated. The British line was now formed anew, and Greene, convinced by the flight of his militiamen and the Maryland continentals that a fresh conflict would result in the annihilation of his army, ordered a retreat. The British lost more than 600 in killed and wounded; the Americans lost about 400 killed and wounded and 850 missing. Notwithstanding his victory, Cornwallis was so much crippled that he retreated on the 18th with the Americans in full pursuit.

**GUILLEMOT**, an arctic web-footed bird, of the family *alcidae*, and subfamily *urinae*, including the genera *uria* (Möhring), *brachyrhampus* (Brandt), and *mergulus* (Ray). The last, to which the little guillemot belongs, has been described under *Auk*. The genus *uria* is characterized by a moderate head; rather long, straight, and pointed bill, with a distinct angle on the under mandible; wings short and point-

ed, with the first quill longest; tail very short; tarsi shorter than middle toe; legs short and robust; toes rather long, fully webbed; claws strong and curved; hind toe wanting. The general form is short and robust, the size never large, and the prevailing colors black and white. There are about seven species, inhabiting the arctic seas between America and Asia, migra-

Guillemot (*Uria grylle*)—Summer Plumage  
a. Head. b. Foot.

ting to temperate regions during winter. The flight is rapid, with short flaps, near the surface of the water; they are excellent swimmers and divers, but poor walkers from the shortness and posterior position of their legs; they feed on fish and other products of the sea; they deposit usually a single egg, of large size, on rocks overhanging the water, breeding in large companies. The black guillemot (*U. grylle*,

Guillemot and Young—Winter Plumage.

Lath.) is 14 in. long, and 22 in. in extent of wings; the general color in summer is black tinged with green; a large transverse oval spot on the wing, under wing coverts, and axillaries,

white; bill black, and feet red; in winter and in the young plumage, the under parts, neck, and rump are white, the head above and back dark brown. This species is found breeding, about June, from the arctic regions to the bay of Fundy; according to Audubon, it lays three eggs, in a nest composed of pebbles; the eggs are about  $2\frac{1}{2}$  by  $1\frac{1}{2}$  in., of an earthy white color, blotched with dark purplish black toward the larger end; they are delicate and nutritious articles of food, and even the black and tough flesh has proved palatable to many an arctic voyager. There is a variety on the N. W. coast (*U. columba*, Pall.), resembling the preceding, except that the white of the wing is divided by a diagonal band of brownish black. The foolish guillemot (*U. troile*, Linn.; *U. lomvia*, Brün.) is about 17 in. long, and 30 in extent of wings; the general color above is grayish black, tinged with dark brown on the sides of the head and neck; a bar on the wings, and a line encircling and behind the eye, white; under parts white; feet greenish black. It is occasionally found as far south as New York, but breeds in numbers on the coast of Labrador; the female lays a single egg of large size, white with dark blotches, on the bare rock, and, like the other species, plucks feathers from the abdomen over a space large enough to cover the egg; both sexes assist in incubation. The plumage is exceedingly dense, and admirably adapted for a creature exposed to severe cold; the flesh is tough, and eaten only by hungry seamen; the eggs are highly esteemed as food. They are rapid fliers, and such bold swimmers and divers as to defy the highest waves. The thick-billed guillemot (*U. arva*, Pall.) is probably a mere variety of the last, differing only in its shorter and wider bill. The guillemots allow man to invade their retreats and knock them down with clubs; this apparent apathy is owing to the structure of the bird, which is ill calculated for progression on land, but admirably adapted for a life on the water. The above described species are found also on the northern shores of Europe.—The genus *brachyrhamphus* includes the smaller guillemots, with a larger head, shorter bill densely covered with feathers at the base, curved upper mandible, and in other respects as in the preceding genus. The marbled guillemot (*B. marmoratus*, Gmel.) is about 10 in. long, brownish black above, tinged with ashy on the back, with two white spots on each side of the back; ring round hind neck, and under parts, white, bill black, and feet yellow; the young have the upper feathers with reddish edges, and the under parts spotted and marbled with brownish black and white. Several others inhabit the North Pacific, and are most abundant about the N. W. coast of America. The name of guillemot is given to the horn-billed auk (*cerorhina monocerata*, Pall.) of N. W. America. The habits of all the guillemots are the same; their numbers, beauty, activity, and useful properties have been the admiration of all arctic voyagers,

many of whom have been saved from starvation by their eggs and flesh.

**GUILLEM, John**, an English writer on heraldry, born in Herefordshire about 1565, died in London, May 7, 1621. He was educated at Oxford, subsequently became a member of the society of the college of arms in London, and in 1617 was appointed rouge-croix pursuant of arms. His reputation rests upon the work entitled "The Display of Heraldry," first published in 1610, which has passed through many editions; that of 1724, containing in addition "A Treatise of Honor, Civil and Military, by Captain John Logan," is considered the best. The book was published in Guillim's name, but is said to have been written by John Barkham.

**GUILLOTIN, Joseph Ignace**, a French physician, born in Saintes, May 28, 1738, died in Paris, May 26, 1814. He studied under Antoine Petit, graduated as doctor in medicine in 1770 at Rheims, and became professor of anatomy, pathology, and physiology in Paris. He was one of the commissioners appointed to investigate the experiments of Mesmer in animal magnetism, and joined with Lavoisier, Bailly, and Franklin in their celebrated report upon that subject. In 1788 he increased his popularity by a pamphlet in favor of giving the *tiers état* a representation equal to that of the two other orders, and was elected in 1789 to the constituent assembly. In that body he brought forward various sanitary measures. His name, however, is principally associated with the proposition which he made that decapitation, a mode of punishment previously reserved for nobles and regarded as less ignominious than death by hanging, should be adopted for criminals of all classes. He also proposed that the decapitation should be effected by machinery instead of by the axe or the sword, in order that the suffering might be less. In 1791 Guillotin's motion was renewed in a somewhat altered form by Lepelletier de Saint-Fargeau; and on March 20, 1792, the legislative assembly, on a report presented by Dr. Antoine Louis, the perpetual secretary of the academy of surgery, adopted a resolution ordering a machine for decapitation described by the same to be adopted. This machine, in the invention and construction of which Guillotin had no share whatever, received at first the name of *louisson* or *louisette*, which was soon superseded by that of *guillotine*, first used in a satirical song published in the royalist newspaper *Les actes des apôtres*. Guillotin was imprisoned during the reign of terror, and afterward resumed medical practice.

**GUILLOTINE**, an instrument for inflicting capital punishment by decapitation. It consists of an oblique-edged knife, heavily weighted, sliding easily between two upright grooved posts, and descending on a block where the head of the sufferer rests. This machine, which was brought into use in the early period of the French revolution, is not altogether a

modern invention. Similar contrivances were in use in several parts of Europe during the 16th and 17th centuries, if not before. According to Crusius, in his *Annales Suevici* (1595), such an instrument of decapitation existed in early times in Germany, but was superseded by the sword; it was styled *Fullbeil*, falling hatchet. A representation of it may be seen in two old engravings, the one by Georg Penez, who died in 1550, the other by Heinrich Aldegrever, bearing the date of 1553; and also in an old picture which, according to Reiffenberg, is still preserved in the city hall of Augsburg. Jean d'Autun, the historiographer of Louis XII. of France, narrating an execution which he witnessed at Genoa, May 13, 1507, describes a machine exactly like the guillotine. This is the *mannaia*, which was used in all parts of Italy for the execution of men of rank, and is fully described by Père Labat in his *Voyage en Espagne et en Italie* en 1730. The same had been introduced into southern France, and Puysegur in his *Mémoires* makes an allusion to it on occasion of the execution of Montmorency in 1632. A similar contrivance existed in the Netherlands. The "maiden" of Scotland, which was used in the decapitation of the regent Morton in 1581, and is still preserved in the museum of the antiquarian society at Edinburgh, was an instrument akin to those above mentioned, and either it or at least the pattern of it had been brought from abroad by the very man who suffered by it. The decapitating machine, therefore, was far from being a novelty when Dr. Guillotin suggested its application in 1789. The scheme being submitted to the carpenter employed by the government, he demanded 5,000 francs for making the instrument; but a German named Schmidt offered to build it for a much smaller sum; and finally a bargain was struck at 824 francs, Schmidt contracting to furnish 83 machines of the same kind, one for each department. The machine was first tried, April 18, 1792, upon three corpses at the Bicêtre hospital, and worked so satisfactorily that seven days later it was used publicly for the decapitation of Pelletier, a highwayman under sentence. Sömmering, in the *Moniteur* of Nov. 9, 1795, denounced it as too rapid in its operation, and maintained that sensation does not cease immediately after the head of the sufferer has been severed from the body. The controversy was kept up by Sue, Oelsner, Cabanis, and others. In the same year appeared Sédillot's *Réflexions historiques et philosophiques sur le supplice de la guillotine*, and in 1796 the *Anecdotes sur les décapités*. The question has been renewed at different times and in various forms, particularly in an article in the London "Quarterly Review" for December, 1846, republished separately in 1850; Louis Dubois's *Recherches historiques et physiologiques sur la guillotine* (Paris, 1843); and Ludovic Lalanne's *Curiosités des traditions, des mœurs et des légendes* (1847).

**GUILMETH, Alexandre Auguste**, a French archaeologist, born at Brionne, Eure, Dec. 2, 1807. He was educated at the college of Bernay, and has been successively master of studies in the college of Rouen, inspector general in that of Amiens, and censor and superintendent in the colleges of Dieppe and Juilly. He early devoted himself to the study of the archaeology of Normandy, and has published many historical works on its celebrated localities and cities, including Brionne, Pont-Audemer, Évreux, Dieppe, Havre, Yvetot, and Elbeuf, all of which have been collected under the title *La description historique de la Normandie* (12 vols. 8vo, 1836-'50), with plans and engravings. A *Notice biographique et littéraire sur A. A. Guilmeth* was published in 1860.

**GUIMARAENS** (Port. *Guimarães*), a town of Portugal, in the province of Minho, between the Ave and Vizella, 32 m. N. E. of Oporto; pop. about 8,000. The town stands on a gentle slope, nearly surrounded by an amphitheatre of hills, is generally well built, and has several good streets and public squares. It is fortified, and contains an ancient castle, with square towers at the angles and in the middle of each side. The keep, which is in the centre, is entered at mid-height by a wooden bridge. Among the public buildings are a fine collegiate church called the cathedral, a Dominican convent of the 14th century, and a hospital. There are manufactories of cutlery, iron ware, paper, leather, cotton, and linen; and large quantities of plums and figs are exported. Near by are hot sulphur springs, which have been frequented for centuries. Guimaraens is said to have been founded by Celts about 500 B. C. Henry of Burgundy made it the capital of Portugal in the beginning of the 12th century. Here began the reign of King Wamba, which is the proverbial expression for chronological indefiniteness.

**GUINAND**, a Swiss optician, born in the canton of Neuchâtel about 1745, died in 1825. He was the son of a house carpenter, and constructed a telescope in imitation of one of great value in the possession of his employer, so like the model that it was difficult to decide which of the two was better. At 40 years of age he commenced the manufacture of lenses for telescopes. Some of these coming under the observation of Fraunhofer, the well known instrument maker of Bavaria, he engaged the services of Guinand for a number of years, solely for his skill in this manufacture. In the latter part of his life Guinand was occupied in constructing telescopes of great size and power, every part of which was the work of his own hands. (See GLASS, and LENS.)

**GUINEA**, an English gold coin, first struck in the reign of Charles II., of gold which had been brought from the coast of Guinea, whence its name. Its value is 21 shillings, or about \$5 12. Guineas have not been coined since 1817, when they were superseded by the sovereign, and have now become rare.

**GUINEA**, a name applied to all the W. coast of Africa between Cape Verga, lat.  $10^{\circ} 19' N.$ , and Cape Negro, lat.  $15^{\circ} 41' S.$ ; that part N. of Cape Lopez, about lat.  $1^{\circ} S.$ , being called Upper Guinea, and that S. of it Lower Guinea. Its coast line exceeds 3,500 m.; its breadth is indefinite, but it is considered to extend inland from 200 to 300 m. Upper Guinea, or Guinea proper, comprises the district of Sierra Leone, the Grain coast (including Liberia), the Ivory coast, the Gold coast (including Ashantee), the Slave coast (including Dahomey), Benin, Yoruba, Biafra, and several other small native kingdoms. From Cape Lopez the coast line runs nearly N., but bends gradually W. to Cape Formosa, forming the bight of Biafra, in which are the islands of Fernando Po, Prince, and St. Thomas. From Cape Formosa to Cape Palmas the coast trends westward, forming the bight of Benin in its course; and beyond Cape Palmas it has a general N. W. direction to Cape Verga. The waters between Capes Lopez and Palmas are called collectively the gulf of Guinea. Near Sierra Leone are high promontories and abrupt headlands clothed with tropical verdure. Cape Palmas receives its name from the immense palm groves which cover the undulating plains extending from it far inland. The Gold coast is rocky and bold, but not high, and at Accra becomes flat and sandy. Along the Slave coast are extensive salt marshes and lagoons, with outlying sand banks, and inland grassy plains which are converted into swamps in the rainy season. Near the equator, where the hills approach the sea, mountain scenery and tropical luxuriance greet the eye. From the latitude of Sierra Leone to the Quorra river extend the Kong mountains, nearly parallel to the coast and at a distance from it of from 100 to 300 m.; and from the shores of the bight of Biafra rise the Cameroons mountains, which extend far eastward. Numerous rivers drain this slope into the Atlantic, the chief of which are the Scarcios, Sierra Leone, Gallinas, Cape Mount, St. Paul's, Cavalla, Assinie, Tenda, Bossum Prah, Volta, Quorra or Joliba (ancient Niger), and its affluent the Tchadda, Old Calabar, Cameroons, Quaqua, and Gaboon. The climate is hot, oppressive, and insalubrious. At Cape Coast Castle the mean temperature during the hottest month is from  $85^{\circ}$  to  $90^{\circ} F.$ ; at the Gaboon it is  $84^{\circ}$ . The heat is uniform and debilitating, and malarious fevers prevail wherever the coast is low. Tornados are common, and in December, January, and February, a dry N. E. wind, called the harmattan, fills the atmosphere with fine sand. The most valuable minerals are gold and iron, which are usually found in granitic or schistose rocks; gold is also obtained in the beds of some of the rivers. The interior is rich in virgin mines of the latter mineral. The forests, which cover a large proportion of the surface, abound in magnificent trees, among which are the baobab and the palm. Oranges, lemons, grapes,

pepper, sugar cane, cotton, indigo, tobacco, maize, millet, rice, yams, potatoes, various gums and dye woods, and ginger are among the other vegetable productions. The animals are cattle, of tough and ill-flavored flesh, sheep, horses, and goats (all of which are of poor breeds), elephants, buffaloes, jackals, tiger cats, hyenas, leopards, deer, hares, porcupines, sloths, monkeys, lizards, rats, and mice. Cats and dogs have been introduced from Europe; the latter speedily degenerate, but are valued as food by the natives. Pheasants, partridges, snipes, turtle doves, birds of beautiful plumage, serpents, scorpions, centipedes, toads, frogs, locusts, and crocodiles are numerous; and the coasts abound with excellent fish, and are rich in coral and ambergris. The natives are divided into numerous tribes, the principal of which are the Mandingoes, Fantees, Ashantees, Dahomans, Egbas, Benins, and Fans. The Mandingoes claim to be Mohammedans; the others are pagans. All have a general resemblance in physical characteristics and customs. When the slave trade was the most flourishing branch of commerce on the coast, the chief occupation of most of these tribes was war for the sake of procuring captives to sell to the traders. The principal European settlements are Sierra Leone, the American colony of Liberia, the British Gold Coast colony, and the British settlement of Lagos and its dependencies. The French trading stations have recently been abandoned, and the Danish and Dutch forts on the Gold coast have been ceded to Great Britain. The French settlement at the Gaboon is now reduced to a mere coaling station. St. Thomas and Prince islands, in the gulf of Guinea, belong to Portugal; Fernando Po, Corisco, and Annabon to Spain. The most important articles of barter imported into Upper Guinea are lead, iron, firearms, gunpowder, cotton and woollen goods, brass vessels, salt, spirits, tobacco, and beads, which are exchanged for valuable woods, ginger, pepper, gums, rice, gold, palm oil and kernels, ground nuts, ivory, and wax.—Lower Guinea, extending from Cape Lopez to Cape Negro, comprises Loango, Congo, Angola, and Benguela. Its coast line follows a general N. N. W. direction, and is unbroken by any important indentation. It is traversed from N. to S. by a range of mountains, called by the Portuguese the Crystal or Salt mountains, which are covered with dense forests. The principal rivers are the Okanda or Ogobai, Zaire or Congo, Coanza, and Cuvo. Congo, Angola, and Benguela are claimed by the Portuguese, who have their capital at St. Paul de Loanda.—The Guinea coast was discovered by the Portuguese in 1487. A tribe called Genahoa, N. of the Senegal, are said to have been the first blacks encountered by them; and afterward the name was applied indiscriminately to all the peoples further south.—For a fuller description of the country, see the articles on its various divisions.

**GUINEA, Gulf of**, that part of the Atlantic which washes the shores of Upper Guinea between Capes Palmas and Lopez, including the bights of Benin and Biafra. It receives the rivers Assinie, Tenda, Bossum Prah, Volta, Quorra or Niger, Old Calabar, Cameroons, Quaqua, Gaboon, and many smaller streams, and contains Fernando Po, Prince, and St. Thomas islands. It has two currents, one setting eastward from Cape Palmas and the other coming from the south; they meet in the bight of Biafra and unite in one gradually expanding stream, which flows thence N. W., W., and S. W.

**GUINEA FOWL**, or **Pintado**, a gallinaceous bird, of the turkey family, and genus *numida* (Linn.), characterized by a moderate bill, with arched culmen and upper mandible overhanging the lower, and lateral margins smooth and curved; nostrils large, oval, and partly covered by a membrane; wings moderate, with the fifth quill longest; tail short and pendent; tarsi longer than middle toe, without spurs, covered in front with broad divided scales; toes moderate, the anterior united at their base by a

Guinea Fowl (*Numida meleagris*).

membrane, the hind toe short and elevated; claws short and very slightly curved. There are five species described by Gray, all of which have the head more or less naked, with fleshy caruncles below the bill, and some with a callosous crest; the neck is long and slender, the body stout, and the feathers of the rump have an inflated appearance. They are peculiar to Africa, where they frequent woods on the banks of rivers in flocks of 200 or 300, scattering in search of food, which consists of grains, grasshoppers, ants, and other insects; when alarmed, they attempt to escape by running rather than flight; the eggs are numerous, and laid in a slight nest in a bush or thicket. The common Guinea or pea fowl (*N. meleagris*, Linn.) is slate-colored, covered all over with rounded white spots, and is about the size of the domestic cock. It was well known to the ancients, by whom it was domesticated for the sake of its flesh, and who named it *meleagris*. Guinea fowls are very noisy and troublesome, always quarrelling with the other inmates of the poultry yard; they are hard to raise, from the delicacy of the young and their liability to

disease; their flesh is of fine flavor, and their eggs are excellent. They are not profitable to the farmer, are great eaters, requiring to be fed beyond what they can pick up by themselves, and are apt to injure tender buds and flowers. One male suffices for 10 females; they lay in May or June 16 to 24 eggs, with a hard shell, of a yellowish white color with small brown points; they are poor sitters and not very tender mothers; incubation lasts three weeks, and is best performed by the common hen. The crested pintado (*N. cristata*, Pall.) has a crest of black feathers, and the body black with blue spots; the mitred pintado (*N. mitrata*, Pall.) has the head surmounted by a conical helmet, and is black, white spotted. Both these species have the same habits as the first, and could be as easily domesticated.

**GUINEA GRASS**, a name which, as well as Guinea corn, is applied in the southern states to *sorghum cernuum*, a grass closely related to broom corn; but instead of having an erect panicle like that, its flower clusters are nodding. Like many other plants that have been introduced into cultivation and abandoned when found valueless, this remains, where the climate is favorable to it, as a weed. It gives an acceptable forage in the West Indies and parts of Florida, where better grasses do not succeed.

**GUINEA PIG**, a South American rodent, of the subfamily *caviina*, and genus *cavia* (Klein). It will be seen that the common name conveys two erroneous impressions, as the animal is not found in Guinea, nor is it a pig; the term Guinea is doubtless a corruption of Guiana, and the name pig derived from the grunting noise made by it when hungry. The wild Guinea pig, or restless cavy (*C. aperea*, Linn.), is about 10 in. long, with a thick heavy body; short, wide, erect, and transparent ears; large, prominent eyes; head and snout like those of a rabbit, with white incisors; short neck and legs; four toes before, and three behind, unconnected by any membrane; and a long, rather coarse fur. The colors are black and dirty yellow above and on the sides in distinct pencils, the former prevailing on the back and upper surface of the head, the general tint being a dark grayish brown; the throat and abdomen a dirty yellow. The characters in the subfamily have been given in the article **CAVY**. The distinguishing characters from the subgenus *cerodon* are the larger size of the hind lobes of the molars, these lobes in the upper teeth having an indenting fold of enamel on the outer side, and the corresponding half of the lower with its deep fold on the inner side. It is found from about lat. 35° S. through Paraguay, Bolivia, Brazil, and perhaps as far N. as Guiana. Its food is entirely vegetable, and its time of feeding toward evening; it prefers marshy places covered with aquatic plants; it generally lives in societies of from 6 to 15 individuals, and its presence may often be detected by the beaten paths among the plants; it breeds only once a year, and has one or two young at a birth. The

restless cavy is generally believed to be the animal from which the domestic Guinea pig (*C. cobaya*) originated; but Mr. Waterhouse thinks it more probable that a pretty variety, such as may occur in all wild animals, attracted the attention of Europeans, who captured and domesticated it for its harmless disposition as well as its beauty, and by care perpetuated the race of the common Guinea pig. The animal is known by its black, white, and fulvous patches, irregularly distributed, and its short, close, and shining hair. It is exceedingly gentle in disposition, never attempting to defend itself by teeth or nails, simply making very slight efforts to escape, and uttering a sharp cry. Its remarkable fecundity alone preserves it from extinction; it is capable of fecundation at the age of six or eight weeks, and brings forth after three weeks' gestation from four to twelve at a birth, according to the age of the mother, who reaches her full development in nine months; lactation lasts about 15 days, and the female is ready for another fecundation;

Guinea Pig (*Cavia cobaya*). a. Teeth. b. Skull.

the young are born covered with fur, and with the eyes open. They are very sensitive to cold and damp; the flesh is not eaten, and the skin is useless, the only reasons for keeping them being their gentleness and beauty; there is a popular belief that their odor drives away rats. Their food is entirely vegetable, and they drink but seldom and by lapping; they will eat the usual green food of rabbits, but prefer parsley and carrot tops to the bread, milk, and meal upon which they are generally fed; they are fond of apples and other fruits, and remarkably so of tea leaves. Though cleanly in their habits, they have a disagreeable odor; like hares, they sleep with their eyes half open. Scarcely any two animals can be found with the same markings; the dark tortoise-shell ones are the most highly prized.

**GUINEA WORM.** See *ENTOZOA*, genus *filaria*, vol. vi., p. 670.

**GUIPÚZCOA**, one of the Basque provinces of Spain, bordering on the bay of Biscay, France, and the provinces of Navarre, Álava, and Biscay; area, 728 sq. m.; pop. in 1870, 180,743.

The coast is indented with numerous harbors. The principal rivers, all of which are small, are the Deva, Urola, Oria, and Bidassoa. The surface is an alternation of mountain, hill, and valley, and the scenery is highly romantic and picturesque. The climate is humid, mild, agreeable, and healthful. From the mountainous nature of the country, however, agriculture is prosecuted with difficulty. The chief minerals are iron, argentiferous lead, copper, marble, and gypsum. The province is traversed by a railway which passes through Tolosa. The principal manufactures are of iron. The inhabitants are honest, industrious, and brave. (See *BASQUES*.) The chief towns are St. Sebastian, the capital, Irun, Tolosa, and Fuenterrabia. The Pheasants' island in the Bidassoa is celebrated as the place where the peace of the Pyrenees was concluded in 1659 between France and Spain.

**GUISCARD, Robert**, the founder of the kingdom of Naples, born about 1015, died July 17, 1085. His father, Tancred de Hauteville, a petty Norman baron, had twelve sons, of whom Robert was the sixth. As the paternal estate was insufficient to support so large a family, the three eldest sons went to Italy, where they secured rich possessions in the Norman colony of Apulia, of which they eventually became the leading nobles. Attracted by their success, the younger brothers also went to Italy, and Robert, who was surnamed Guiscard, the prudent or adroit, showed so much valor and address that on the death of his brother Humphrey in 1057 he was proclaimed count of Apulia, to the exclusion of the young son of the latter. He soon after overran Calabria, and received from Pope Nicholas II. the title of duke of both provinces, with the additional grant of whatever portions of Italy or Sicily he could wrest from the Greek schismatics or the Saracens. With the aid of his younger brother Roger he conquered Sicily, and ejected the Saracens from their remaining possessions in southern Italy. The kingdom of Naples had its origin in these conquests. Robert, having subsequently undertaken to annex the duchy of Benevento to his dominions, was brought into collision with Pope Gregory VII., who claimed the territory as a grant from the emperor of Germany. The pope excommunicated him, but a reconciliation was soon effected. In 1081, under the pretext of sustaining the rights of Constantine, son of the dethroned emperor Michael VII., who had married his daughter, he invaded Epirus and other provinces of the Byzantine empire, and after a series of victories was in full march for Constantinople, when he was recalled to Italy to relieve the pope, who was besieged by the emperor Henry IV. in the castle of Sant' Angelo. At Guiscard's approach Henry drew off his forces; but the populace having refused to receive the Normans, Rome was sacked by them, and a large portion of it burned. The pope, fearing to remain in the city, followed his

liberator to Salerno, where he died soon after. Guiscard immediately sailed with a large fleet for the Grecian archipelago, but died of an epidemic disease at Cephalonia on the eve of his departure for Constantinople.

**GUISCHARD**, or **Guischardt**, **Karl Gottlieb**, a German writer, born in Magdeburg in 1724, died in Berlin, May 15, 1775. He studied at Halle, Marburg, and Leyden, with the intention of becoming a clergyman; but changing his mind, he entered the military service of Holland. After a single campaign, in which he served as ensign in an infantry regiment, peace having been restored by the treaty of Aix-la-Chapelle, he devoted himself to research upon military art in ancient times, and published in 1758 at the Hague his *Mémoires militaires sur les Grecs et les Romains*. Frederick the Great summoned the author to Breslau, bestowed upon him the name of Quintus Icilius by which he was afterward known, and gave him a major's commission. In this capacity Guiscard was called into service in Saxony, where he was charged with extortion. The king nevertheless promoted him to a colonelcy in 1763, and continued to treat him with favor. In 1773 he published at Berlin his *Mémoires historiques et critiques sur plusieurs points d'art militaire*, which he dedicated to Frederick. This work is written with clearness and a thorough knowledge of the subject.

**GUISE**, a town of France, in the department of Aisne, on the Oise, 23 m. N. of Laon; pop. in 1866, 5,099. It is a fortified place of the third class; has various manufactures and a phalanstery designed for 400 families. It is the birthplace of Camille Desmoulins. It is first mentioned in the 11th century. From it the dukes of Guise derived their title.

**GUISE**, **House of**, a branch of the ducal family of Lorraine, which played a conspicuous part in the religious and civil wars of France in the 16th century. Its most celebrated members were the following. **I. Claude de Lorraine**, first duke of Guise, born Oct. 20, 1496, died in April, 1550. He was a younger son of René, duke of Lorraine, whom he succeeded as count of Aumale. He established himself in France, where he rendered distinguished service to Francis I., who erected the former countship of Guise into a duchy, which he bestowed upon him, together with the government of Champagne. His daughter Marie married James V. of Scotland, and was mother of Mary queen of Scots. **II. François de Lorraine**, second duke of Guise, born at the castle of Bar, Feb. 17, 1519, died Feb. 24, 1563. Almost from the outset of his career he was distinguished as a good general and a brave soldier; and by his successful defence of the city of Metz (1552-'3), when he obliged Charles V. to raise the siege after having lost 30,000 men, he became renowned throughout Europe. He also signalized himself at the battle of Renti in 1554. At the request of Pope Paul IV. he was sent to Naples at the head of a French army

in 1556; but he failed in this undertaking. Montmorency having lost the battle of St. Quentin (1557), the kingdom was in imminent danger; but Guise repelled the imperial troops, and retook Calais from the English, who had held it since 1347. On the accession of Francis II., in 1559, Guise seized the reins of government, and caused Antoine de Bourbon, king of Navarre, and the prince of Condé to be arrested, and the latter placed on trial for high treason; but the death of the king (1560) deprived him of his ascendancy. With the constable Montmorency and Marshal Saint-André he then formed a kind of triumvirate in order to control the course of the government and to oppose the Protestants. An assault in 1562 on a body of Huguenots by some of his servants and followers gave the signal for the wars which continued for more than 30 years. At the head of the Catholics, Guise took Rouen, and a little later won the victory of Dreux, where Montmorency fell into the hands of the Protestants, and Saint-André was killed. He had reached the height of his power when, during the siege of Orleans, he was treacherously shot, Feb. 18, 1563, by a Protestant, Poltrot de Mérey, and died a week after. He left a diary, which was printed in Michaud and Poujoulat's *Nouvelle collection de mémoires pour servir à l'histoire de France*. **III. Henri I. de Lorraine**, third duke of Guise, son of the preceding, born Dec. 31, 1550, assassinated in Blois, Dec. 23, 1588. He witnessed his father's death, and swore vengeance against the Protestants, and especially Admiral Coligni, who he thought had instigated the deed. When 16 years old he went to Hungary and distinguished himself in the war against the Turks. After his return to France he fought at Jarnac and Moncontour, and forced Coligni to raise the siege of Poitiers in 1569. He was an abettor of the massacre of St. Bartholomew's day (1572), and was present when Coligni was killed. In 1575, having been wounded in the face in a successful encounter in the vicinity of Château-Thierry, he received the surname of *le Balafre*, the scarred, by which he was afterward commonly known. The following year he was instrumental in the formation of the "holy league" for the protection of the Catholics, of which till his death he was the head. After the death of the duke of Anjou, in 1584, he covertly aspired to the throne; and being supported by the pope and Philip II. of Spain, he excited the nation against Henry III. and his heir apparent Henry of Navarre. During the "war of the three Henries" he twice defeated, at Vimory and Aulneau, the German troops which had been enlisted in aid of the Huguenots. Notwithstanding the prohibition of Henry III., he entered Paris in triumph, besieged the king in the Louvre, May 12, 1588, during the popular rebellion known as the "day of the barricades," and remained the undisputed master of the capital. At the end of the same year he was present at the meeting of the states gen-

eral at Blois, and demanded to be appointed high constable and general-in-chief of the kingdom. The royal authority was placed in the utmost danger, when Henry caused Guise to be assassinated by some of the royal body guard. The duke's brother, the cardinal of Guise, who had participated in all his plans, was privately despatched in the following night. **IV. Charles de Lorraine**, fourth duke of Guise, son of the preceding, born in 1571, died in 1640. After the assassination of his father he was imprisoned at Tours, whence he escaped in 1591, and went to Paris. In the intrigues of the league he took part against the duke of Mayenne. The estates of Paris were at one time disposed to marry him to a Spanish infanta, and raise him to the throne. Subsequently he went over to Henry IV., who made him governor of Provence. Under Louis XIII. he joined the party of Maria de' Medici, and was obliged to take refuge in Italy, where he died. **V. Henri II. de Lorraine**, fifth duke of Guise, son of the preceding, born in Blois, April 4, 1614, died June 2, 1664. Being a younger son, he first entered the church; at 12 he possessed nine abbeys; at 15 he was promoted to the archbishopric of Rheims; but on the death of his elder brother he gave up a profession ill suited to his character, and when his father died in 1640 he was put in possession of the title of duke of Guise. His many follies and love adventures gave him notoriety. He meanwhile took part with the opponents of Richelieu, was sentenced to death in 1641, and fled to Belgium, where he married the countess of Bossut. After the death of Louis XIII. he returned to France, and indulged in every excess, distinguishing himself occasionally in battle by his bravery. About this time he fell in love with a Mlle. de Pons, and in order to bring about his union with her he went to Rome to solicit the dissolution of his former marriage. While there, hearing of the revolt in Naples under Masaniello, he resolved to conquer a throne which he could offer to his mistress. At the head of 20 followers, he left Rome Dec. 13, 1647, embarked on a felucca, and landed at Naples amid the applause of the population; but his overbearing manner soon disgusted the Neapolitans, who deserted him and delivered their city into the hands of the Spaniards. He was taken prisoner, April 6, 1648, carried to Spain, and kept in confinement till 1652. In 1654, with the help of the French government, he sailed again for Naples, but entirely failed in his enterprise. Returning to France, he was appointed grand chamberlain, and passed the rest of his life at the court. A narrative of his first expedition to Naples was published by his secretary, Saintcyon, under the title of *Mémoires de feu M. le duc de Guise, contenant son entreprise sur le royaume de Naples jusqu'à sa prison* (4to, 1668). **VI. Louis Joseph de Lorraine**, sixth and last duke of Guise, nephew of the preceding, born in 1630, died in 1671. He succeeded his uncle in 1664,

and married the daughter of Gaston, duke of Orleans. He died childless, and the title and estates of Guise passed to Marie de Lorraine, daughter of the fourth duke, who died in 1688 without having been married. **VII. Louis de Lorraine**, cardinal de Guise, brother of le Balafré, born at Dampierre in 1555, assassinated at Blois, Dec. 24, 1588. He became archbishop of Rheims in 1574, and cardinal in 1578. He played a prominent part in the intrigues of the league, and made himself especially odious to Henry III. At the states general of Blois, in 1588, he presided over the clergy, found fault with the king's speech, and forced him to alter several passages. He was assassinated by order of the king. **VIII. Louis de Lorraine**, cardinal de Guise, nephew of the fifth duke, born about 1580, died in 1621. He entered the church, although his inclination was for a military career, and in 1615 became archbishop of Rheims and cardinal. In 1621 he accompanied the king in an expedition to Poitou, where he died. By Charlotte des Essarts, one of the mistresses of Henry IV., he had five children. It is said that he was secretly married to her, and that among his papers was found a dispensation from the pope granting permission for the marriage.

**GUITAR** (Gr. *kithára*; Span. *guitarra*), a musical stringed instrument, chiefly used to accompany the voice. It was known to the Egyptians in a form somewhat similar to that in present use for more than 15 centuries before the Christian era, and was probably introduced into Europe in modern times by the Spaniards, who derived it from the Moors. The Spanish guitar consists of a hollow wooden body of a somewhat oval form, about 18 in. in length by 4 in depth, and of a neck of 16 in., having a finger board with 17 frets. The strings, six in number, generally tuned E, A, D, G, B, E, are distended along the instrument, passing over a bridge at the lower end of the body, and being regulated by pegs at the upper end of the neck. They are set in vibration by the fingers of the right hand, while the left is employed to produce the modulations of tone by pressing against the frets on the finger board.

**GUIZOT. I. François Pierre Guillaume**, a French statesman and historian, born in Nîmes, Oct. 4, 1787, died near Paris, Sept. 13, 1874. His father, a Calvinist lawyer, having died on the scaffold in 1794, he was taken by his mother to Geneva, where he received a classical education. In 1805 he went to Paris to study law; but he soon became engrossed in literary pursuits. He began to contribute largely to journals and periodicals, and exhibited a strength and maturity of intellect which soon brought him into notice. In 1809 he published his first work, entitled *Nouveau dictionnaire des synonymes français* (2 vols. 8vo), which was followed by *Annales de l'éducation*, *De l'état des beaux arts en France et du salon de 1810*, an annotated translation (from various pens) of Gibbon's "Decline and

Fall of the Roman Empire," *Vies des poètes français du siècle de Louis XIV.*, &c. In 1812 he was appointed assistant professor of modern history in the Sorbonne. In the same year he married Mlle. Pauline de Meulan, whose relations with the royalist party opened for him a political career, on which he entered at the fall of Napoleon. He was appointed secretary general of the department of the interior in 1814, of justice in 1815, master of requests in 1816, and councillor of state in 1817. He upheld the principles of the constitutional party by his political essay *Du gouvernement représentatif et de l'état actuel de la France* (1816), and thus became the mouthpiece of those who at a later period were known under the name of *doctrinaires*. Under the semi-liberal Decazes ministry he was director general of the communal and departmental administration, which post he resigned in February, 1820, on the fall of that cabinet. He now published his political pamphlet, *Du gouvernement de la France depuis la restauration et du ministère actuel*; and the following year, *Des moyens de gouvernement et d'opposition dans l'état actuel de la France* (1821). His strictures on the government were followed by his removal from the council of state, and ultimately he was ordered to discontinue his lectures in the Sorbonne, which he had published previously under the title of *Histoire du gouvernement représentatif* (1821-'2). He then devoted his time to literary pursuits, producing in succession a remarkable introduction to a revised French translation of the works of Shakespeare; *Essais sur l'histoire de France du cinquième au dixième siècle* (1823), an appendix to Mably's *Observations*; biographical sketches and historical notes to the *Collection des mémoires relatifs à la révolution d'Angleterre* (26 vols., 1823 et seq.), translated from the English by various writers, and to the *Collection des mémoires relatifs à l'histoire de France*, from its origin to the 13th century (31 vols., 1823 et seq.); the first two volumes of his *Histoire de la révolution d'Angleterre*, to the accession of Charles II. (1827-'8); and several essays and papers in periodicals. In January, 1828, he established the *Revue Française*, which was published every two months, nearly on the plan of the English quarterlies. In 1827 he lost his wife, and in the following year he married her niece, Mlle. Élisabeth Dillon, who lived only till 1833. In 1828 the Martignac ministry restored to him his chair at the Sorbonne and his seat in the council of state; and his eloquent lectures, which were delivered in conjunction with those of Cousin and Villemain, raised him to the highest popularity. They were published under the titles *Histoire générale de la civilisation en Europe depuis la chute de l'empire romain jusqu'à la révolution française* (1828), and *Histoire générale de la civilisation en France depuis la chute de l'empire romain* (1830). He entered the chamber of deputies in January,

1830, taking his place among the opposition, bore a part in the parliamentary proceedings which brought about the revolution of July, and was minister of the interior in the first cabinet of Louis Philippe. He resumed his seat in the chamber of deputies on Nov. 3, opposed the Lafitte cabinet, and supported that headed by Casimir Périer. After the death of the latter he entered the coalition ministry formed Oct. 11, 1832, under the presidency of Marshal Soult, in which he was minister of public instruction. After the dissolution of that ministry, Feb. 22, 1836, Guizot remained in comparative retirement for a few months. He resumed his post in the Molé cabinet, but soon quarrelled with his colleagues, resigned office, and joined the opposition. After the fall of Molé he was appointed ambassador to Great Britain, Feb. 9, 1840, being the first Protestant ambassador sent to that country by France since the time of Sully. He was recalled in October to succeed M. Thiers in the ministry of foreign affairs, in the last cabinet of Louis Philippe's reign. For more than seven years, in concert with the king, he upheld the system of peace at any price abroad, and of opposition to democratic reform at home, which eventually resulted in the overthrow of the Orleans dynasty. He succeeded in restoring the French government to a participation in the settlement of the eastern question, but the subordinate position in which England and Russia held France, and which the latter apparently did not resent, aroused a discontent that was not allayed by victories won in Algeria. Meanwhile the agitation for electoral reform was beginning in Paris, and propagating itself over the country. Guizot, who in 1847 had succeeded Soult as head of the ministry, evinced his contempt for what he considered a trifling matter, and reluctantly consented to resign his office, Feb. 23, 1848, when the revolution had actually commenced. He fled to England, where he published, in January, 1849, a pamphlet entitled *De la démocratie en France*. He returned after an absence of about a year, and was defeated in Calvados as a candidate for the chamber of deputies. In 1861 he declared himself in favor of the maintenance of the temporal power of the pope, which gave rise to much discussion both in France and in England. In 1870 he supported the ministry of Ollivier, and declared himself in favor of an affirmative vote on the *plébiscite*. Guizot was a member of three departments of the French institute, having been elected to the academy of moral and political sciences in 1832, to that of inscriptions and belles-lettres in 1833, and to the French academy in 1836. In 1872 he received from the academy the biennial prize of 20,000 francs. In the same year he resigned his membership in the Protestant synod. In March, 1874, he objected to Ollivier's panegyric of Napoleon III. in the academy; and subsequently hearing that the latter had paid his son's debts, he insisted upon refunding the

amount, and for that purpose sold for 120,000 francs a famous picture of Murillo which the queen of Spain had given him. His principal works, besides those already mentioned, are: *Monk: Chute de la république et rétablissement de la monarchie en Angleterre en 1660* (1850); *Corneille et son temps, and Shakspeare et son temps* (1852); *Histoire de la république d'Angleterre et du protectorat de Cromwell* (2 vols., 1854); *Histoire du protectorat de Richard Cromwell et du rétablissement des Stuarts* (2 vols., 1856); *Sir Robert Peel: Étude d'histoire contemporaine* (1856); *Mémoires pour servir à l'histoire de mon temps* (8 vols., 1858-'68); *L'Église et la société chrétienne en 1861* (1861); *Discours académiques* (1861); *Histoire parlementaire de France, &c.* (a collection of his speeches, 5 vols., 1863); *Méditations sur l'essence de la religion chrétienne* (1864); *Méditations sur l'état actuel de la religion chrétienne* (1865); *Mélanges biographiques et littéraires* (1868); *La France et la Prusse responsables devant l'Europe* (1868); *Histoire de France depuis les temps les plus reculés jusqu'en 1789, racontée à mes petits-enfants* (1870 et seq.); *Histoire de quatre grands chrétiens français* (2 vols., 1873-'4). For many years he was engaged in writing a history of Spain, to be completed in 10 vols., of which 5 were finished. He began to learn Spanish for this work at the age of 72. Among his editorial prefaces and memoirs, his admirable *Étude sur Washington*, prefixed originally to the *Vie, correspondance et écrits de Washington*, is particularly worthy of mention. Almost all his works have been translated into English, and all the more important ones into several other languages. **II. Élisabeth Charlotte Pauline de Meulan**, a French authoress, first wife of the preceding, born in Paris, Nov. 2, 1773, died there, Aug. 1, 1827. Her family was left in reduced circumstances by the death of her father in 1790, and she devoted herself to literature for support. In 1800 she published *Les contradictions*, a novel, and soon after *La chapelle d'Ayton*, partly an adaptation from the English. In 1801 she undertook the literary and artistic editorship of *Le Publiciste*, a periodical established by Suard. In 1807, being compelled to abandon her labors by ill health, she accepted the aid of an anonymous writer, who proved to be Guizot, then young and unknown. The intimacy arising from this incident ripened into love and ended in their marriage, April 12, 1812. Thenceforth she devoted herself principally to works for the moral improvement of the young, and published successively *Les enfants* (1812); *Le journal d'une mère* (1813); *L'Écolier, ou Raoul et Victor* (1821), to which the academy awarded the Montyon prize; *Nouveaux contes à l'usage de la jeunesse* (1823); and *Lettres de famille sur l'éducation* (1826), which also gained a prize. Several volumes of her essays and tales were published by her husband after her death. **III. Marguerite An-**

**drée Elisa** (DILLON), niece of the preceding and second wife of François Guizot, born in Paris in 1804, died in 1833. She also cultivated letters, and furnished to the *Revue Française* a number of articles and tales, which were collected in a volume and published in 1834. Of her children, HENRIETTE, born in 1829, wife of Conrad de Witt, has published *Edouard III. et les bourgeois de Calais, ou les Anglais en France* (1854), *Une famille à Paris* (1863), and several books for children, and has translated a number of English works, including the life of Prince Albert, attributed to Queen Victoria, "China and Japan," by Laurence Oliphant, and "William Pitt and his Times," by Lord Stanhope. PAULINE, born in 1831, wife of Cornélius de Witt, brother of her sister's husband, wrote *Guillaume le Conquérant, ou l'Angleterre sous les Normands* (1854), and made translations from the English, including novels by Dickens and Miss Mulock, and, in collaboration with her sister, Motley's "Rise of the Dutch Republic." She died at Cannes, Feb. 28, 1874. MAURICE GUILLAUME, the only son, born in Paris, Jan. 11, 1833, received a prize from the French academy in 1853, for a work entitled *Ménandre, étude historique et littéraire sur la comédie et la société grecques* (1855). In 1866 he was appointed professor of the French language and literature in the collège de France. He has also published *Alfred le Grand, ou l'Angleterre sous les Anglo-Saxons* (1856), and translations of Macaulay's essays.

**GUJERAT.** See GUZERAT.

**GULF WEED.** See ATLANTIC OCEAN, vol. ii, p. 79.

**GULL**, a web-footed bird, comprising several genera of the family *laridae*, of which the typical genus *larus* (Linn.) is found over the marine portions of the entire world. The bill varies considerably in form and strength, though it is generally straight, with compressed sides, and curved at the end; nostrils lateral and oblong; wings long and pointed; tail usually even; tarsi robust; anterior toes united by a full web, and the hind toe short and elevated. The genus *larus* contains the largest and best known of the gulls, characterized by a strong hooked bill, nearly even tail, light-colored mantle, and white head. The largest of the gulls is the glaucous or burgo-master (*L. glaucus*, Brünnich), 30 in. long, with an alar extent of 5 ft.; the bill about 3 in., very stout, gamboge yellow, with a reddish orange patch near the end of the lower mandible; the general color is pure white, with a light grayish blue tinge on the back and wings. It is an inhabitant of the arctic seas, coming down in winter as far as New York. It is exceedingly shy, and notoriously voracious, eating fish, small birds, and carrion; it is less noisy than most other species. The eggs are pale purplish gray, with spots of brown and purple. The young, as in gulls generally, are pale yellowish brown, with spots and bars of dusky. The black-backed gull (*L. marinus*,

Linn.) is about the size of the last, from which it may be distinguished by the dark slate color of its back and wings, the black white-tipped primaries, and the yellow legs and feet. It is found from the entrance of Baffin bay to Maine, its favorite breeding places being on

Black-backed Gull (*Larus marinus*).

the coast of Labrador; in winter it goes as far south as Florida. It is a high, powerful, and majestic flier, resembling in this respect, as well as in its voracious habits, the vultures; it breasts the fiercest gales, skimming along the tops of the waves; it is a good walker, a light but slow swimmer, and no diver. It preys upon fish, young birds, eggs, and any floating carrion; in fact, upon everything except vegetable food; tyrannical and strong, it

Silvery Gull (*Larus argentatus*).  
1. Adult. 2. Young. 3. Bill.

is also very cowardly, flying off when the bold little skuas or jagers (*stercorarius*) attack or approach it. It is exceedingly shy, and very noisy in the breeding season; in captivity it is very long-lived. The breeding season is from the middle of May to the middle of June, and

only one brood is raised in a year; the nest, composed of weeds and grasses, is placed upon rocky shelves, and the eggs, usually three, are about 3 by 2 in., of a pale greenish gray, with dark spots and blotches; both sexes take part in incubation, and the young are fed at first by regurgitation. The eggs, like those of gulls generally, are good eating; great numbers of the young, when nearly able to fly, are killed and salted as food for the fishermen of Labrador and Newfoundland; the old birds are tough and unfit for food. The plumage is soft and thick, and is esteemed for pillows and similar articles. The herring or silvery gull (*L. argentatus*, Brunn.) is about 23 in. long, and 53 in alar extent; it resembles a small glaucous gull, except that the first six primaries are marked with black. This is a very shy species, with a powerful and graceful flight; it feeds principally on herring, and on the usual food of gulls. It is found from Newfoundland to Texas, and goes inland to the western rivers and northern lakes; it breeds from Labrador to Maine, nesting, when persecuted by man, on high trees; the eggs, about 3 by 2 in., are usually three, of a dull yellow color with spots and blotches of amber brown, and are excellent as food.—In the genus *chroicocephalus* (Eyton) the bill is moderate, slender, and much compressed; the size is small, and the head in the spring plumage has a dark hood, becoming white in winter; the contrast of black and white makes them very handsome birds. The laughing gull (*C. atricilla*, Linn.), 17 in. long, has the mantle and wings bluish gray, the hood dark leaden gray, and white lines on the lids; found from Massachusetts to Texas. Bonaparte's gull (*C. Bonapartei*, Rich.), about 15 in. long, has a light mantle, grayish black hood, and a white band divided by a narrow black line around the posterior part of the eye; it is found from Nova Scotia to Texas, on the western rivers and lakes, the Pacific coast, and in the fur countries; in the neighborhood of Puget's sound it is eaten by some Indian tribes.—In the genus *rissa* (Leach), including the kittiwakes, the bill is long but strong, and the hind toe rudimentary or very small. The three-toed gull, or kittiwake (*R. tridactyla*, Linn.), 17 in. long, has a pearl-gray mantle, the ends of the outer primaries black, and a general white plumage; it is found from Labrador and the fur countries to the southern coast in winter. There are three other species on the N. W. coast.—The ivory gull (*pagophila eburnea*, Gmel.), about 19 in. long, has an entirely white plumage, with an ivory yellow bill, dusky at the base; all the species of the genus are found far at sea in high northern latitudes, where they feed principally on the flesh and fat of cetacean animals. The larger and the arctic species, the former called goelands, are found also on the European continent. The common gull of Europe is the *L. carus* (Linn.). The larger terns, of similar appearance and habits but smaller size, are often called gulls.

**GULL**, Sir William Withy, an English physician, born at Thorpe-le-Soken, Essex, Dec. 31, 1816. He graduated M. D. at the university of London in 1846, was Fullerian professor of physiology at the royal institution in 1847-'9, and afterward physician to Guy's hospital till about 1867. He was knighted after his successful attendance during a severe illness of the prince of Wales in 1871, and appointed physician extraordinary. He is president of the clinical society. His publications include a lecture on paralysis and treatises on hypochondriasis and on abscess of the brain.

**GUM**, an exudation from certain trees, distinguished by its either softening or dissolving in water, and not yielding to alcohol; also by affording mucic acid, when acted upon by nitric acid. The resins, which resemble the gums in origin and appearance, are insoluble in water, but dissolve in alcohol, ether, and the essential oils, and are moreover distinguished from the gums by their inflammability. The gums, as they issue through the punctured bark of trees, are held in solution in the vegetable juices; and as these evaporate on exposure they form a thick adhesive substance, which by further exsiccation may become dry, hard, and pulverizable. They are mixtures of the calcium and potassium salts of a feeble vegetable acid termed gummie or arabic. By boiling down the juices or the infusions of many plants, a substance of this nature is often obtained, even when the plants are not known to produce it naturally. Flaxseed may thus yield a product, called bassorine, which when dried is like gum arabic. The gummy substances obtained in this way are generally distinguished by the name of mucilage. Though the gums differ in their chemical reactions from amylaceous matter, their elementary composition is usually considered the same, and like that of starch is represented by the formula  $C_6H_{10}O_6$ . Starch acquires the properties of gum when dried at a temperature of  $266^{\circ}$  F. (See DEXTRENE.) Gums possess little if any dietetic value, since experiment has shown that they merely dissolve or swell up in the intestinal fluids, without being changed to sugar, and are absorbed, if at all, only in an exceedingly small quantity. It is said, however, that gum arabic is used as food by some savage and semi-barbarous tribes; but reports of this character are hardly sufficient to set aside the data of exact experiment. Mucilaginous fluids are given to invalids as agreeable drinks, and are of benefit in sheathing inflamed surfaces and protecting them from irritation. It appears, however, from Dr. Hammond's experiments, that the insertion of large quantities of gum may irritate the mucous membrane of the bowels, and therefore it should not be administered too freely, especially to infants. Properly given, it is of use in dysentery, diarrhoea, and inflammation of the bowels, chest, and bladder. It may be advantageously added to diuretics.—Several varieties of gum are recognized, most of which may be re-

ferred to one or other of three divisions. Those of the first, distinguished by their solubility in water, are chiefly composed of the peculiar principle arabine, and are represented by gum arabic, the purest of the gums. The second division comprises those which soften and swell in water without dissolving, as gum tragacanth, Bassorah gum, &c. They are in great part composed of arabine, but also contain the principle bassorine. The third division includes those that are partially soluble in water, and are distinguished by the presence of the principle cerasine. The gums of the cherry and many other fruit trees belong to this group.—GUM ARABIC may be used as a generic name for the various gums produced by the several species of acacia, many of which are particularly designated by their localities, as the Turkey or Arabic gum, the Barbary or Morocco gum, Cape gum, East India gum, gum Senegal, &c. The first named is the product principally of the *acacia vera* and *A. Arabica*; it is collected mostly in Upper Egypt, Nubia, Kordofan, and Darfour, and is brought from different ports of the Mediterranean. The second is supposed to be obtained from the *A. gummifera*, and is brought from Mogadore and Mazagan. The Cape gum is from the Cape of Good Hope, the product of a species of acacia resembling the *vera*, and named by Burchell the *capensis*. The East India gum, mostly from Bombay, is the product of different species of acacia. Gum Senegal, from Senegambia, is supposed to be obtained from *A. Senegal*, *A. vera*, *A. Seyal*, and *A. Adansonii*. The first named of these is a small tree which forms vast forests in the hottest regions of Africa. These varieties of gum arabic differ somewhat in purity, hardness, and color. The best real gum arabic is in rounded or amorphous tears, some of which are as large as nutmegs, some transparent, and some opaque, of light shades of yellow, sometimes red, also white, and of glassy lustre. The gum has a sweetish taste, but no decided odor. Its specific gravity varies from 1.3 to about 1.5. It is readily dissolved in boiling water; but the solution more slowly effected in cold water keeps better. It has an acid reaction, and alcohol added to it causes the gum to fall as a white precipitate. Gum arabic is used in the arts for producing a glazed surface upon fabrics, as also for stiffening or giving to them a body, answering the same purpose as starch. By increasing the density of liquids in which it dissolves, these are made to retain substances in suspension which would otherwise subside. It is for this purpose introduced into writing ink and various preparations of pigments and of medicines. It is also administered for its own medicinal qualities, which are chiefly of a demulcent character. It is not susceptible of fermentation under the influence of yeast, but if digested with cheese and chalk it may be made to furnish alcohol. Its nutritive property has already been noticed. The gum is often adulte-

rated with inferior gums, and also with starch and flour. Iodine readily detects the presence of starch or of flour in solutions of gum containing them by the blue color produced.—GUM TRAGACANTH, also called GUM DRAGON, is the product of various species of *astragalus*, especially the *A. verus* of the north of Persia, Armenia, and Asia Minor, and the *A. gummifer* of Arabia, Mt. Lebanon, &c. It is collected in the months of July and August from the natural exudations of the shrubs, and from those resulting from incisions made in the stem near the root. It is a hard, tough substance, more or less white according to its purity, in very irregular flattened shapes, and in tortuous vermicular filaments. It may be pulverized after drying at a temperature of 212°. It has no taste or smell. Its specific gravity is 1.384. It swells slowly in water, partially dissolving, and forms a thick adhesive paste. By boiling with sufficient water, a solution is obtained of similar appearance, and Brande thinks of the composition, of that of gum arabic. Different analyses are given of it, but that of Guérin-Varry is generally adopted; it is as follows: arabine, 53.3 per cent.; bassorine or tragacanthine, 33.1; water, 11.1; inorganic matter, 2.5. Starch is detected in very small quantity in the bassorine. From the ultimate analysis the same chemist deduced the formula  $C_5H_{10}O_6$ . The uses of gum tragacanth are similar to those of gum arabic. Apothecaries employ it to give adhesiveness to the ingredients of pills, and confectioners apply it with a similar object to the materials of lozenges. Gum of Bassorah, from Bassorah near the head of the Persian gulf, is of this class of gums, and furnishes the name for the peculiar principle they contain.—CHERRY-TREE GUM, including in this name the exudations of the peach, plum, and other kindred trees, is an inferior quality of gum, somewhat like gum arabic, and consisting of a portion soluble in cold water, which is arabine, and a portion insoluble, which is the principle named by M. Guérin-Varry cerasine. (For gum kino, see KINO.)—GUM MEZQUITE is the product of the mezquite tree (*prosopis glandulosa*) of Texas and New Mexico, brought to notice in 1854 by Dr. Shumard of the United States army. It is described as similar in its properties to gum arabic, exuding spontaneously from the tree, and concreting into tears and lumps of variable sizes, semi-transparent, and of lemon white to dark amber shades of color. It is brittle and easily pulverized, and the fractured surfaces are brilliant. From an ounce to 3 lbs. has been obtained from a single tree, and more, no doubt, by making incisions in the bark. The branches furnish a purer quality than the trunk. The best time for collecting it is the latter part of August. The trees abound upon the plains over regions thousands of miles in extent, and flourish luxuriantly in dry and elevated situations. If the gum could be easily obtained in large quantities, it would become

an important commercial article; but an abundant exudation takes place only in unusually dry seasons after an interval of several years. Specimens have been analyzed by Dr. Campbell Morfit with the following results: arabine, 84.967; bassorine, 0.206; water, 11.640; inorganic matter, 3.000; impurities, 0.236; total, 100.049. Elementary composition: carbon, 44.706 per cent.; oxygen, 48.794; hydrogen, 6.500. It thus shows a close resemblance to gum arabic and gum Senegal in composition as well as in its physical and chemical properties. It is kept in the drug stores of the Mexican cities, and considerable quantities have been sent to San Francisco from the Mexican ports on the Pacific.—This country receives its supplies of gums in great part through England.

**GUMBINNEN**, a town of Prussia, capital of a district of the same name, in the province of East Prussia, on the Pissa, 68 m. E. of Königsberg; pop. in 1871, 9,085. The town, lying on both sides of the river, is regularly built, and contains three Protestant churches, a public library, a school of midwifery, a gymnasium, and two hospitals. It has manufactories of woollen and linen cloth and hosiery, beer, and liquors, and a considerable trade in corn and cattle. Gumbinnen owes its prosperity largely to the fact that it gave asylum to Protestants, chiefly from Salzburg, who fled thither from persecution about the year 1732. Previously it was but an insignificant village.

**GUMBO**, a southern name, probably derived from the negroes, of a stew or soup, usually made of chicken, and thickened with the mucilaginous pods of the okra. When these cannot be obtained, saffrafras pith or tapioca is used as a substitute. (See OKRA.)

**GUM RESINS**, inspissated juices of certain plants, obtained by spontaneous exudation or from incisions purposely made. They consist of resin and gum, the proportions varying in the different varieties, and with these are commonly associated essential oil, and other vegetable substances, as starch, bassorine, extractive, &c. They are most of them hard and dry substances, brittle and opaque, rarely translucent like the resins. Some that are semi-liquid and viscid, as the sagapenum and galbanum, become hard in very cold weather, and may then be pulverized. At a moderate heat these are sufficiently fluid to be strained through a cloth; and all the gum resins may be thus strained and purified by first boiling them in water. They are partially soluble in water or in alcohol, and wholly so in a mixture of these. In water alone the gum dissolved holds for a time the finely divided resinous portion suspended, and thus emulsions are prepared for administering the substances in medicine, which is their principal use. Balsams are distinguished from gum resins by containing benzoic acid. The most important gum resins are described in separate articles, as aloes, ammoniac, asafoetida, bdellium, euphorbium, galbanum, gamboge, myrrh, sagapenum, scammony, &c.

**GUM TREE.** See BLACK GUM.

**GUN.** See CANNON, MUSKET, and RIFLE.

**GUN COTTON**, an explosive substance obtained by subjecting common cotton to the action of strong nitric acid, first brought to public notice in 1846 by Prof. Schönbein of Basel, Switzerland. Several products are known under this name, possessing distinct properties, though differing slightly in constitution. Cotton fibre is nearly pure cellulose,  $C_{18}H_{30}O_{16}$ , and by the action of the acid a number of equivalents of nitric oxide,  $N_2O_4$ , or  $NO_2$ , are substituted for an equal number of hydrogen. The number of equivalents substituted varies from 6 to 9, according to the strength of the acid. Thus, the substitution of 9 equivalents would give  $C_{18}H_{21}(NO_2)_9O_{16}$ , or more simply,  $C_6H_7(NO_2)_3O_5$ . Water is also generated in the reaction, by the union of hydrogen with the oxygen set free in reducing nitric acid to oxide. In preparing the gun cotton, two or three parts of strong sulphuric acid are mixed with one part of nitric acid, to absorb this water and thus prevent further hydration of the nitric acid. The following formulas show the constitution of the products obtained by using two or three parts of sulphuric and one of nitric acid, while the quantity of water is varied: 1. With monohydrated acids:  $C_{18}H_{30}O_{16} + 9(HNO_3) = C_{18}H_{21}(NO_2)_9O_{16} + 9H_2O$ . 2. With 3 to 4 parts water:  $C_{18}H_{30}O_{16} + 8(HNO_3) = C_{18}H_{22}(NO_2)_8O_{16} + 8H_2O$ . 3. With 4 to 5 parts water:  $C_{18}H_{30}O_{16} + 7(HNO_3) = C_{18}H_{23}(NO_2)_7O_{16} + 7H_2O$ . 4. With 5 to 6 parts water:  $C_{18}H_{30}O_{16} + 6(HNO_3) = C_{18}H_{24}(NO_2)_6O_{16} + 6H_2O$ . The first variety is the well known detonating gun cotton. It is insoluble in common ether and alcohol, and is not attacked by acetic acid, but is soluble in acetic ether. The second is a less explosive variety, soluble in common ether with one eighth of alcohol added, but insoluble in acetic acid. The third is inflammable, but not ordinarily explosive, and is soluble both in ether and in glacial acetic acid. This variety is used for colloidon. The fourth is always dissolved in the acid, from which hitherto it has not been isolated. In the manufacture of gun cotton the substitutions are never exactly in accordance with the foregoing formulas, but most probably different degrees of substitution take place in the different molecules of the same mass of cotton; and a careful analysis shows invariably an intermediate constitution, though in many cases one of the typical constitutions is very closely approached. Gun cotton is not readily distinguishable in appearance from the unaltered cotton; but it is slightly harsher to the touch and the compression of the fingers. When moistened with a solution of iodine in potassium iodide, and touched with a drop of dilute sulphuric acid, it turns yellow, while unchanged cotton under the same test turns blue. The variety here to be considered is the detonating product,  $C_6H_7(NO_2)_3O_5$ . To prepare it the strongest commercial acids are required, the nitric acid having a density of near

1.50, and the sulphuric a density of 1.847. An immersion of the cotton for a few seconds yields an explosive material; but to insure the highest degree of explosiveness the immersion should be prolonged. Baron Lenk protracted it to 48 hours. On withdrawing it from the bath, as much acid as possible is squeezed out between porcelain plates, and the cotton is repeatedly and thoroughly washed in water. The fibres are capillary, and during the immersion the tubes absorb acid, which it is difficult to remove entirely. As the so-called spontaneous ignition of gun cotton has been frequently attributed to the retention of acid, the original method of washing the unbroken fibre in water has been abandoned, and a new mode of treatment, devised by Mr. F. A. Abel, has been extensively applied in England. The fibre is first subjected to two or three rinsings in a large volume of water, and is freed from water as far as possible after each rinsing, by a centrifugal drying machine. It is then reduced to pulp by an engine similar to that used in reducing paper pulp. The access of water to the capillary tubes is thus greatly facilitated, and to insure the most searching purification, the pulp is transferred to a "poaching machine," where it is beaten about, and kept suspended in a large volume of warm water, continuously renewed, and rendered slightly alkaline at the close of the operation. This operation lasts about 48 hours, and the quantity treated is half a ton. In this way a thorough intermixture of the products of many dippings is obtained, and the average constitution is rendered uniform. The pulp is then compacted into the desired forms by a preliminary moulding and a subsequent pressing by hydraulic power, ranging from four to six tons per square inch. On leaving the press the slab contains about 20 per cent. of water, in which condition it may be safely cut with circular or band saws, and even hot iron may be used without danger to burn holes in it. When wet it may be kept for an indefinite period without change, and, whether wet or dry, it is affected by very few reagents. Its stability is superior to that of gunpowder in every respect save the all-important one of immunity from inexplicable explosion. Repeated accidents have destroyed the confidence of all but the most sanguine in its safety. It was for a time supposed that the ingenious process of Mr. Abel had removed the causes of distrust; but a terrible and unexplained explosion at Stowmarket in 1871 revived the feeling, which still prevails. How far the repeated disasters attending the use and storage of gun cotton are due to the carelessness of those who have it in charge, is unknown, for it leaves no witnesses to testify to the origin of the explosions, and the very mystery which surrounds them, and our frequent inability even to conjecture a probable cause, are sufficient reasons for regarding it as a treacherous servant. If massive gun cotton be ignited by a coal or flame of low

intensity, it burns in the open air inexplosively. If ignited by a powerful flame, it flashes like gunpowder; but if ignited by a fulminate, it detonates with tremendous violence. This "sympathetic" quality, by virtue of which the total combustion seems to follow the character of the ignition, is difficult to explain, and also presents some anomalies. According to Mr. Abel, about five grains of fulminate of mercury is required to produce detonation; but ten times that quantity of chloride of nitrogen, strongly confined, is required to produce the same result, while 350 grains of nitro-glycerine, exploded in contact with massive gun cotton, fails to produce any other result than the mechanical disintegration of the mass. The rate at which detonation is propagated along a row of gun-cotton disks has been investigated by Mr. Abel and Capt. A. Noble, who found it to be about 18,000 feet a second. A sound wave would travel through such a mass with less than one fourth of this velocity, and such rapidity of transmission seems explicable only on the assumption that ignition is carried along the surface by the expanding gases, driven by their tension. The products of combustion of gun cotton vary with the conditions under which it is exploded. They consist of varying proportions of carbonic oxide, carbonic acid, marsh gas, nitric oxide, nitrogen, and water. Two analyses by Lieut. Von Károlyi of the Prussian army gave, by volume:

CONSTITUENTS.	I.	II.
Carbonic oxide .....	28.55	28.95
Carbonic acid .....	19.11	20.82
Marsh gas .....	11.17	7.24
Nitric oxide .....	8.83	....
Nitrogen .....	8.56	12.67
Carbon .....	1.85	1.82
Aqueous vapor .....	21.93	25.34
Hydrogen .....	....	8.16
Total .....	100.00	100.00

The first analysis is that of gases obtained by exploding the cotton *in vacuo*, and the second by exploding it in strong iron tubes placed in a mortar.—Many attempts have been made to substitute gun cotton for gunpowder in military operations. A brief examination of the phenomena of explosions will show that it can never be advantageously used as an agent for the propulsion of projectiles. In the explosion of all detonating compounds the conversion of the solid or liquid material into elastic gases is so rapid that it may be regarded as practically, though not strictly, instantaneous. The subsequent expansion of these gases by their elastic force must be the motive power of the shot; and at the instant of concussion this is so great, in the case of gun cotton confined in a small receptacle, that no material can withstand it, unless the chamber be much larger than the bulk of the gun cotton. If the explosive energy be reduced by using a large chamber, or by mixing the compound with some inert material, then the total elastic effort is no greater

than that of gunpowder. It can be rendered serviceable in this relation only by depriving it of the very excess of energy which can alone give greater velocity to a projectile; and there is no probability that any means can be employed to compensate for this loss of energy, as may be done with gunpowder. As a bursting charge for hollow projectiles, the destructive efficiency of gun cotton is very great; but experience has shown its extreme liability to explode prematurely by the shock of the discharge. Its detonation in contact with hard materials shatters or disintegrates them. Wood and rock are completely pulverized by it, while hollow projectiles are often blown into innumerable fragments. But these effects extend to a small distance only from the centre of explosion, and at the distance of a few feet the effect is no greater than that obtained from gunpowder.—The use of gun cotton in blasting is favored by its indifference to water, and by its great explosive effect, estimated by Combes and Flandin to be fourfold, by Séguier sixfold, and by Tamper double that of gunpowder. These estimates are based upon practical experiment. They indicate a saving in practice by the use of shallower bore holes. But the relative costliness of gun cotton, the danger of premature explosions in charging holes, its varying quality, its liability to spontaneous decomposition, and its too rapid combustion, which gives it a tendency to shatter or pulverize rather than lift and loosen the rock, have proved great obstacles to its use. Many of these objections have been obviated, it is asserted, by the manufacture of compound gun cotton above described, and by the admixture of less explosive or non-explosive substances, such as common cotton. Extensive and successful use was made of gun cotton in the quarries of Comorn and in the removal of the ancient walls of Vienna. In the former case, the cotton was wound in solid cylinders; in the latter the cylinders were hollow. Punshon, an English manufacturer, claims that he makes an article of definite explosive power in grades, suited to any use, the quality of each grade being uniform. He also asserts that his gun cotton preparations will not explode or decompose spontaneously, and can be stored or transported without danger. In these preparations, the gun cotton is coated with a powder of sugar, or potash or other salts, which separates the fibres. By changing the quality of this powder the desired grade of exploding force is obtained.—Bleekrode found that gun cotton, when moistened with an inflammable liquid, like carbon sulphide, ether, benzine, or alcohol, and ignited by the electric spark or otherwise, does not explode, but burns slowly. Hence he recommends that when stored it should be covered with such a liquid, which could be removed by evaporation. A new variety of gun cotton is made by immersing cotton for 15 minutes in a saturated solution of chlorate of potassa. It is chemically more allied appa-

rently to the chlorate of potassa powders. Little is known of its application. A new gun cotton, known as gadoxyline, is manufactured in Wolverhampton, England. Its composition is unknown. Gun cotton has been manufactured into an explosive paper, to reduce the danger of handling and charging.

**GÜNDERODE, Karoline von**, a German poetess, born in Carlsruhe, Feb. 11, 1780, committed suicide July 26, 1806. She became canoness of a chapter in Frankfort, and under the name of "Tian" wrote a number of poems remarkable for passionate feeling. She formed an attachment for the philologist Creuzer, which terminated unhappily, and led to her suicide. She was intimate with Bettina von Arnim, who published their correspondence under the title of *Die Günderode* (2 vols., Grünberg, 1840; translated by Margaret Fuller, Boston, 1842). Her literary remains consist of *Gedichte und Phantasien* (Hamburg, 1804), *Poetische Fragmente* (Frankfort, 1805), and *Gesammelte Dichtungen* (Mannheim, 1857).

**GUNDUK**, a river of Hindostan, which rises N. of the Himalaya mountains, and flows through that chain in a S. E. direction to Hajepoor, where it falls into the Ganges, in lat.  $25^{\circ} 39'$  N., lon.  $85^{\circ} 16'$  E. Its course is estimated at 400 m. The scenery where it emerges from the Himalaya range is magnificent. In the upper part of its course it is called Salgrami, from a singular species of stones found in its channel; they are mostly round, and are generally perforated in one or more places.

**GUNDWANA**. See GONDS.

**GUNNEL**. See BLENNY.

**GUNNERY**, the art of using guns, gunpowder, and projectiles. The forces which are of moment in gunnery as affecting the course of projectiles are terrestrial gravitation and the resistance of the air. The former is so nearly uniform, both in amount and direction, that it may be so regarded. But the difficulties which appear when we investigate the resistance of air are so formidable, that hitherto mathematicians have utterly failed to find a general formula, and have been obliged to resort to purely empirical methods. The first quantity to be sought is a unit of resistance with which all other degrees of resistance may be compared; and this is usually taken as the resistance offered by the air to a body having a front 1 foot square, moving 1 foot in 1 second. This quantity cannot be determined theoretically, but it is found by careful trial that the value of this unit depends upon the form of the front, as well as its area. It is also considerably influenced by the shape of the rear. Hutton has given the following ratios between the values of the resistance:

Hemisphere, convex side foremost .....	119
Sphere .....	124
Cone, point foremost, with a vertical angle of $25^{\circ} 42'$ .....	126
Disk .....	285
Hemisphere, flat surface foremost .....	288
Cone, base foremost .....	291

In these ratios it appears that the resistance to the cone is about the same as that to a sphere, notwithstanding the sharp point of the former. From recent experiments by Prof. Bashforth of Woolwich, it also appears that the resistance to an elongated shot with a hemispherical front is less than that to a spherical shot of equal diameter, in the ratio of 1:345 to 1:531. Newton, in his *Principia*, gives as the front of least resistance a figure having nearly the section of a pointed Gothic arch. In practice it has been found that the "pointed ogive" or pointed Gothic arch gives less resistance than any other front hitherto experimented with. Investigators have therefore been compelled to determine the values of the unit independently for every kind of projectile in use. The dependence of resistance of air upon velocity is also determined experimentally. The latest and most trustworthy researches, by Prof. Francis Bashforth of the Woolwich artillery school, show that for velocities ranging from 1,400 to 1,700 ft. a second the resistance varies nearly as the square of the velocity; for those between 1,100 and 1,400 ft. it varies more nearly as the cube of the velocity; while for still lower velocities the ratio is in some power higher than the cube. Thus a 15-inch shot, moving 1,500 ft. a second, encounters a resistance amounting to nearly a ton and a half, while a 10-inch shot encounters about three fourths of a ton at the same velocity. The amount of resistance offered by the air, and many other important data in gunnery, are ascertained by measuring the velocity of a projectile in different parts of its path. This is accomplished by means of an electro-velocimeter. The projectile is made to break a series of electric circuits at several points, separated by equal intervals. The electric circuit passes through a machine, which contains a cylinder revolving at a known rate, and by appropriate devices the ruptures of the circuit make visible marks upon this cylinder. By measuring the distance between these marks, and multiplying it by the rate of revolution, the time which elapsed between any two instants of rupture becomes known.—Besides retardation, projectiles moving in air are subject to deviations resulting from their rotary motions about their axes. Spherical shot are always made of smaller diameter than the bore of the gun from which they are fired; the difference in the two diameters being termed windage. One of its consequences is, that spherical shot are subject to a series of rebounds from side to side or from top to bottom of the bore, which is called balloting, and which causes them to leave the bore with a rotary motion. Let us suppose, for instance, that at the last ballot (rebound) the shot strikes the right side of the bore, as in fig. 1, receiving a rotary motion in the direction indicated by the arrows. This motion, combined with the motion of translation, tends to augment the pressure of the opposing air in the direction A  $\lambda$ , and to diminish it in the di-

rection  $A r$ ; and the result is the deflection of the path of the shot to the right. Hence the effect of the last ballot in the case supposed is, first, to throw the shot to the left, while the unequal pressure of the air gradually deflects it back again to the right. If the final ballot

FIG. 1.

were on the left side, the deflections would be reversed; if upon the top, the range would be slightly increased; and if upon the bottom, the range would be diminished. These effects were investigated, and the results demonstrated experimentally, by Magnus. They are much aggravated when, by reason of irregular density, the centre of gravity of a ball does not coincide with its centre of figure. They are greater in small than in large projectiles for three reasons: 1. The actual amount of windage is very nearly the same for all calibres, and hence is relatively less for larger calibres than for small ones; therefore the balloting and consequent rotation will be less. 2. Large projectiles can be made more nearly isotropic than small ones, and the centres of figure and of gravity are more nearly coincident. 3. The effects of resistance of air are very nearly proportional to the surface exposed, *i. e.*, to the square of the calibre; while the inertia of the shot and its consequent power to resist these effects is proportional to its mass, *i. e.*, to the cube of the calibre. No projectiles have less lateral deviation than the largest round shot, whether the range be long or short; but the deviations of small spherical shot are notoriously great. In using elongated projectiles, the purpose is to reduce the total resistance encountered in passing through the air and through the target. This is attained by reducing the area of resistance, while the mass is not reduced. Less velocity is lost by them in consequence of the smaller front they offer to atmospheric resistance, as compared with spherical shot of equal weight. After reaching the target they are required, in order to penetrate it, to make smaller holes than spherical projectiles of equal weight, and hence, with an equal striking velocity, will penetrate further. To secure these advantages, the elongated shot

FIG. 2.

must always move with its axis as nearly as possible tangent to its path. But there are several causes which tend to make it rotate about its shortest axis, or tumble. To prevent this, and to give stability to the position of the long axis, a rotary motion about this axis is

given to the projectile. This motion is totally distinct from the rotation of spherical projectiles just described, and the resulting effect of resistance of air is altogether peculiar. By reference to fig. 2 it will be seen that if the axis of the projectile were always parallel to its initial position, the curvature of the path would cause the resistance of air to act more and more upon the lower side, while the air upon the upper side would be rarefied in the wake of the projectile. The rotation upon the condensed air beneath causes it to roll to the right or left, according to the original direction of rotation; to which deflection the name drift is given. But in reality the axis does not continue parallel to its initial position. It describes very slowly a conical surface, the apex of which is the centre of gravity of the shot; and what is most singular, the direction of this axial motion in pointed projectiles is opposite to that of flat-fronted projectiles. The conical rotation (or precession) of the axis causes an increased drift, the amount of which is even greater than the rolling drift already described. With pointed shot this deviation is to the right, but with flat-fronted shot to the left. The point of the former also droops, turning obliquely downward and to the right; the flat front turns obliquely upward and to the left. During the flight the former is more nearly tangent to the path than the latter. For uniform projectiles, the drift at moderate ranges is tolerably constant, and may be allowed for in sighting; but for round shot it is hopelessly irregular, sometimes to the right and sometimes to the left. At long ranges the drift of the elongated shot also becomes irregular, and often excessive, amounting sometimes to 200 or 300 yards to the right of the object sighted. There are also vertical deviations, causing over- or under-shooting. In many cases these errors are more serious than lateral drift; for instance, against a battalion of troops, the hull of a vessel, the crest of a parapet, or the body of a deer, where the object is more extended laterally than vertically, and is more liable to be missed by vertical than by lateral error. There is another kind of error which may be called longitudinal deviation, or variation in range. A series of projectiles fired under conditions as nearly alike as practicable will differ in range; partly because no two charges of powder can be made to give exactly the same initial velocity, and partly because slight differences in the forms of the projectiles occasion marked differences in the amount of vertical drift. Hence the form of the trajectory is of great importance. To avoid vertical errors as much as practicable, it is desirable to give a high velocity to the shot; since the swifter its motion, the less curvature will gravitation produce in its path. It is evident that a low or flat trajectory is more dangerous to an enemy than a high one; but the former requires a higher velocity in the projectile than the latter. The trajectories of spherical shot are at

first less curved than those of elongated shot; but in the latter part of the flight, at considerable ranges, this relation is reversed. This is because the initial velocity of round shot is almost always greater, and the terminal velocity less, than that of elongated shot; the curvature everywhere being very nearly proportional to the velocity. The so-called "dangerous space" is that part of a projectile's path which is not higher above the earth than 5 ft. 10 in., or the stature of a man. The dangerous space is evidently greater at short than at long ranges, since it depends upon the angle which the descending branch of the trajectory makes with the earth, being greater the less the angle of descent; and the longer the range the greater is the angle of descent; for, to obtain the longer range, the muzzle of the gun must be more elevated, and the descending branch, owing to the resistance of the air, always makes a larger angle with the earth than the ascending branch.—The force of a projectile is measured by the product of its mass into the square of its velocity. The force, although a prime factor in the efficiency of a projectile, is not the only one; for cases may arise in which the energy is too great. Thus in firing at a wooden vessel, a shot with a slow motion, making a large irregular hole, and hurling splinters, will be more destructive than a swift shot, cutting cleanly through, with comparatively little injury. In curved fire from mortars and howitzers, a low velocity is not only necessary, but desirable. Most of the effects of projectiles are accomplished by penetrating the objects against which they are directed, and their work will generally be most effectively accomplished when their energy is moderately in excess of that required for complete penetration. In this connection the penetration of iron vessels becomes of great interest and importance.—The most systematic experiments to ascertain the effect of shot on iron targets have been summarized by Capt. W. H. Noble of the English artillery, who deduces the following rules: 1. If two shot, having the same diameter and form of head, strike with equal energy, the penetration will be the same, though one may be a light round shot, striking with a high velocity, and the other a long heavy shot, with a low velocity. 2. A plate will be equally penetrated by shot of different diameters, provided the energy on striking is proportional to the diameter. Thus, a 12-inch shot must have twice as much energy as a 6-inch shot, in order to penetrate the same plate. 3. The resistance of plates to penetration varies as the square of the thickness. These rules are subject to certain qualifications, depending upon the shape of the head of the shot. A hemispherical head is disadvantageous, because it tends to bulge laterally, and the same is partially true of a flat-fronted shot. The best form is the pointed ogive, which passes through without materially bulging, and makes a hole no larger than its true diameter. The flat-

fronted shot usually rips out a piece, called a button, in the shape of the frustum of a cone, the larger base being detached from the back of the plate. This is carried into the wooden backing, giving an increased resistance as compared with the ogive. Spherical projectiles are liable to flatten against the target and break in pieces. It is apparent that when flattening occurs the increased diameter involves the necessity of making a larger hole in order to penetrate. The striking velocity may be so great that the projectile will be dashed to pieces by its impact, and its energy partially absorbed in its own destruction, instead of that of the target. This is especially true of spherical shot, fired with heavy charges at short range against thick plates. In comparing the effects of spherical and elongated projectiles against iron plates, many quantities must be considered, some favoring one form and some the other; but the final result is strongly in favor of the elongated form. For penetrating earth and battering masonry, similar considerations are applicable.—Concerning the effective range of guns, there is much popular misapprehension. To the scientific gunner the maximum range is of so little moment that its extent for common infantry bullets or for the heaviest seacoast projectiles is unknown. The longest range known to us was attained by one of Sir Joseph Whitworth's projectiles, viz., about 11,100 yards, not quite  $6\frac{1}{2}$  miles. The efficiency is greatest near the muzzle, and diminishes as the range increases. A range may be considered effective at which there is a reasonable probability of doing injury. For bullets the effective range will depend upon the way in which the enemy's troops are deployed. Against a skirmish line it cannot much exceed 500 yards, but against massed troops it may be as great as 1,500 yards. With field projectiles an enemy may be harassed at 2,500 yards, or even 3,000. In the bombardment of cities the extreme range is sometimes resorted to, on the assumption that a projectile falling anywhere within the line of fortification may work damage. Effective range turns upon the higher question of probabilities of fire.—Thus far we have discussed projectiles only, since their properties constitute the basis of gunnery. Gunpowder is merely the agent for giving them energy, and the gun for giving them direction. When we examine the relations among the three elements, the problem is highly complicated. We have two forces: the inertia of the shot, and the elastic force of the gases evolved by the powder. It is supposed that the metal contained in a given projectile is cast into a solid cylinder, having the diameter of the bore of the gun. Its length is called the column of metal of the projectile, and constitutes a measure of its inertia. Equal velocities will be imparted to different projectiles when the mean intensity of the forces acting upon them during a given time is proportional to their respective columns

of metal. But the intensity of the force of gunpowder is highly variable at different portions of the path along the bore, being very great near the seat of the shot, and rapidly declining toward the muzzle; hence equal velocities will be imparted only when, at different points in the path along the bore, the respective intensities are proportional to the columns of metal. A complete analysis of the relations existing between the force of gunpowder and the motion of the shot in the gun, in terms of time, space, and mass, has never been attempted; it is a very formidable problem, and its chief difficulty is our ignorance of the rate at which the gases are developed and the quantity of heat evolved. But the greater the resistance opposed to the expansion of the gases of gunpowder, the more rapidly will the powder burn and develop gases, and the higher will be their temperature. Such an increased resistance is offered by an increased column of metal; and hence the conclusion that a longer column of metal carries with it the power of developing more force from a given quantity of powder than a shorter one. On the other hand, the shorter column of metal will still have the higher velocity, though the longer will have the greater energy (mass multiplied into square of velocity); the difference in energy in favor of the latter being due to its greater mass, which more than compensates for its lower velocity. But if the quantity of powder is proportional to the column of metal, a larger charge will develop at every moment more gas than a smaller charge, and give a more intense force. But a larger charge occupies more space in the bore, and robs the projectile of a part of its travel, and hence of a part of the time in which it can receive acceleration. Increasing the charge will increase velocity up to a certain point, but beyond that point will diminish it. In small cannon the maximum pressure is probably reached before the shot has travelled three inches, and in large guns before it has travelled a foot. The time occupied by the shot in traversing the bore probably ranges from  $\frac{1}{10}$  to  $\frac{1}{25}$  of a second, and depends mainly upon the length of the bore and the quantity of powder. A bold attempt was made by Rodman in 1858 to measure the distribution of the forces of gunpowder, by placing pressure gauges along the bore to register the pressure at different points; and to measure the time of passing over different parts of the bore, by a series of ruptures of electric circuits. (For a description of the pressure gauge, and the electric velocimeter, see GUNPOWDER, and VELOCIMETER.) It is obvious that an increase either in the column of metal or in the charge involves an increase in the intensity of the pressure of the gases, and hence an increased strain upon the gun. As the strength of a gun is limited, both the column of metal and the charge must be regulated accordingly. It is the maximum pressure which is dangerous. In large guns this diffi-

culty is serious. Not only is a higher pressure produced by the longer column of metal, but the pressure is distributed over a larger area of bore, and the bursting tendency is in the ratio of the product of these two quantities. The greater thickness of walls gives increased resistance, but this increase is in a lower ratio than that of the bursting tendency, and hence large guns are relatively weaker than small ones. To compensate for this difficulty, constructors have resorted to metals of greater strength, and especially have modified the action of the powder, so that the maximum pressures have been reduced, and the subsequent lower pressures have been increased. Thus the total effort of the powder upon the shot is undiminished. (See GUNPOWDER.) The column of metal of a spherical shot is two thirds its calibre; that of an elongated shot is usually between one and three fourths and twice its calibre. The latter limit has been found to be about as great as the strength of the gun will permit in large calibres. It is sometimes exceeded with very little advantage in the smaller and intermediate calibres. The charge of powder varies from one fourth to one tenth the weight of the projectile. With round shot it is sometimes as high as one third; but it is found that the velocity is not much increased when the charge is greater than one fourth. The velocities imparted to round shot vary from 1,400 to 1,750 ft. per second, and those of elongated shot from 1,150 to 1,500 ft.—For a good introduction to the science of gunnery, see "Ordnance and Gunnery," by Major J. G. Benton, U. S. A., and "Treatise on Artillery," by Lt. Col. C. H. Owen, R. A.

**GUNNY**, a coarse cloth made in India of the fibres of two species of *corchorus*, and used for the sacks in which saltpetre, pepper, and other articles are packed for exportation. The bagging itself is also exported. The export of gunny bags and cloth from Calcutta is chiefly to the United States, and they are mainly used at the south for cotton bagging. For the year ending June 30, 1872, the imports of gunny cloth and bags were as follows:

PORTS.	Pounds.	Value.
Baltimore.....	641,262	\$44,207
Boston and Charlestown.....	3,340,723	133,559
New Orleans.....	81,148	4,996
New York.....	7,850,394	310,829
San Francisco.....	218,068	11,240
Savannah.....	8,765	277
Other ports.....	2,244	58
Total.....	12,137,603	\$505,566

There were reexported 654,139 lbs. of gunny cloth and bags, valued at \$34,929, chiefly to England and Turkey. (See JUNE.)

**GUNPOWDER**, a compound of nitre, charcoal, and sulphur, employed as an explosive. Its composition is described in the article EXPLOSIVES. The date and the author of the inven-

tion are buried in obscurity. Sebastian Münster (1544) wrote concerning it that tradition and literature generally ascribed the discovery of "the dreadful cannon" to the year 1380, and that the majority believed the inventor to have been a monk; adding that "the villain who brought into the world so mischievous a thing is not worthy that his name should remain in the memory of men." This allusion refers to "the black Barthel," or Berthold Schwarz, a monk of the Hartz or the Rhineland, concerning whom there is much dispute. The following condensed extract from a long chronological statement, compiled by Rziha, shows the controversy about Schwarz to be of subordinate importance:

A. D.

80. The Chinese (according to tradition) had already obtained from India a knowledge of gunpowder.
215. Julius Africanus (according to Meyer) described its preparation.
668. Callinicus of Heliopolis introduced Greek fire to the Byzantines. This was probably a mixture like gunpowder, with resin and petroleum; it was certainly no fluid, and according to one author was used to project stone balls from pipes. It may nevertheless have been a rocket mixture or a bomb filling.
690. The Arabs used firearms against Mecca, bringing the knowledge of them from India.
811. The emperor Leo employed firearms.
846. Marcus Gracchus, a Greek author (MS. said to be at Oxford), described a mixture of 1 lb. of sulphur, 2 lbs. of charcoal, and 6 lbs. of saltpetre.
830. Leo the Philosopher made rockets for the army of the eastern empire.
1073. King Solomon of Hungary bombarded Belgrade with cannon.
1085. In a naval battle near Toledo, the ships of Tunis shot "fiery thunder."
1098. The Greek ships used artillery against the Pisans.
1232. The Tartars employed "fire pipes" against the Chinese.
1233. Don Jaime threw into Valencia fiery balls which burst.
1247. Seville was bombarded with artillery.
1249. Damietta was defended against St. Louis with bombs, which on this and other occasions were much dreaded by the crusaders.
1280. Death at Cologne of Albertus Magnus, a preaching monk, said by some ancient writers to have invented "*bombardam, bombardulam et scolpum manuale*."
1294. Death of Roger Bacon, in whose works the destructive qualities of saltpetre, and the production of terrible thunder and lightning from its compounds, are alluded to as well known.
1303. Reported date on an ancient cannon, now in the arsenal of Amberg, Bavaria.
1308. The Spaniards had artillery before Gibraltar.
1311. Henry VII. bombarded Brescia with "thunder guns."
1312. The Arabs had cannon before Baza.
1326. Martos was attacked with artillery.
1330. Berthold Schwarz is said to have discovered gunpowder. Different authors say 1320, 1354, and 1380. MSS. in the monasteries perhaps informed him.

From this time on, the allusions to the use of gunpowder become far more numerous and authentic. Plainly, its military use was revived in Germany, and carried thence to Italy. There is record of a powder mill at Augsburg in 1340; and in 1344 (or 1357, or 1366) Petrarch described the terrible effects of the newly invented but already widely used powder and cannon. They are said to have been employed at Alicante in 1331, at Pui Guillaume in 1338, at Salado in 1340, at Algeciras in 1342, and at Crécy in 1346. In 1378 the English had 400 cannon before St. Malo. In 1397 mines were exploded with powder before Merat; and the same tactics were employed on a larger scale

at Belgrade in 1441, at Milan in 1523 (with poor success), and by the Turks in 1529 at Vienna, and in 1565 at Malta. England imported gunpowder from Sweden and elsewhere until 1560, when its domestic manufacture began.—The employment of gunpowder for blasting rocks is far more recent than its military use. The following dates and memoranda will convey an epitome of its history in this respect: In 1613 Martin Weigel, chief superintendent at Freiberg, proposed boring and blasting in the mines. Traditions of an earlier use in Germany have probably arisen from confounding the ancient method of building fires in the mines, to crack the hard rocks, with that of blasting. It was about 14 years before the new method was successfully introduced in Germany. Reckoning from 1613, the process was carried to England by German miners after 57 years, to Sweden after 111 years. For 72 years the bore holes were closed with solid plugs, instead of clay tamping; for 83 years the practicability and advantage of small holes were unknown; and for more than a century the operation of blasting was considered as merely auxiliary to the work of the pick, gad, hammer, and chisel. (See BLASTING.)—The manufacture of gunpowder has been greatly improved from time to time in mechanical details, affecting both the safety of the process and the quality of the product. The first step is the preparation of the ingredients. The original impurities in a solution obtained by leaching saltpetre earth are nitrates of soda, lime, and magnesia; chlorides of potassium, sodium, calcium, and magnesium; sulphate of lime, various salts of ammonia, and organic substances (humus) partly held in solution by carbonate of ammonia. By the processes of the saltpetre manufacture these impurities are reduced to two principal ones, the chlorides of potassium and sodium, which are still contained in the commercial saltpetre. These salts, which if allowed to remain would attract moisture and deteriorate the powder, are removed by a simple process of refining, based upon their relative solubility at different temperatures. The proportions that will be dissolved by 100 parts of water at various temperatures (centigrade) are as follows:

SALTS.	0°	12°	16°	18°	45°	97°	100°
Saltpetre.....	13·8	....	....	29·0	74·6	236	400
Chloride of potassium ....	29·3	34·5	35·0	....	....	....	57·0
Chloride of sodium.....	35·5	36·0	....	....	....	....	39·9

It will be seen that the solubility of chloride of sodium does not greatly increase with temperature. If desirable, the chloride of potassium can be altogether transformed into chloride of sodium by the addition of nitrate of soda, which by a double decomposition yields both chloride of sodium and additional saltpetre. A crude material, containing say 4,800 lbs. of saltpetre, 360 lbs. of chloride of potas-

sium, and 840 lbs. of chloride of sodium, would be refined by simple recrystallization, somewhat as follows: Half the mass would be dissolved in 1,200 lbs. of water, and heated to 100° C., while the remainder was added. This would dissolve also all the chloride of potassium, but leave a large part (516 lbs.) of the chloride of sodium. From the solution the organic impurities are removed by adding a little glue, boiling, and skimming, after which the temperature is allowed to fall to 18° C., at which point about 4,452 lbs. of saltpetre will be precipitated, 6 lbs. of chloride of sodium, and no chloride of potassium. A further recrystallization will reduce still more the amount of impurity. This is the outline of the process adopted. It is modified by operations intended to hinder the formation of large crystals of saltpetre, which always contain enclosed portions of the mother liquor. The final product should never contain more than  $\frac{3}{100}$  of 1 per cent. of chlorides. In fine sporting powders the proportion of chlorides is usually not more than  $\frac{1}{100}$ , or sometimes  $\frac{2}{100}$ , of 1 per cent. After a thorough drying by heat, the saltpetre is ground to the finest possible state, either with millstones or in mills specially constructed.—Charcoal is the principal form of carbon capable of giving an explosive gunpowder. Graphite or anthracite, when substituted, yields a compound which burns with some vigor, but not explosively. The causes of this peculiarity are not known with certainty. The wood selected for the charcoal is usually the young shoots of alder and willow. The bark being removed, they are placed in iron retorts and subjected to distillation, expelling the greater part, sometimes nearly the whole, of the hydrocarbons. Three grades of charcoal are recognized: red charcoal, containing about 8 or 9 per cent. of hydrocarbons, and having a strong red tinge; brown charcoal, containing 4 to 5 per cent. of hydrocarbons; and black charcoal, containing about 1 to 2 per cent. The red charcoal makes the strongest powder, and is generally used for the sporting variety; the black, and sometimes the brown, is preferred for heavy ordnance. The sulphur selected is refined brimstone; flowers of sulphur is objectionable because it contains sulphuric acid. The mixture is commenced by pulverizing the charcoal and sulphur together. They are rolled in barrels with small iron balls for about six hours, and are ultimately reduced to extreme minuteness. The saltpetre is then added, and another rolling with zinc or copper balls is given. The mixture is then carried to the mill, where it is moistened with water, and placed in a large circular pan or trough, in which iron wheels, weighing several tons and having broad treads, are rolled by machinery, triturating and kneading the powder into the most intimate mechanical union. The milling is the dangerous part of the process, and a year seldom passes at a powder manufactory without one or more explo-

sions at the wheel mills, though the precautions are such that these accidents are seldom disastrous. The powder withdrawn from the wheel trough is very lumpy and irregular; it is therefore reduced by a breaker to a fine meal, in which condition it is transferred to a very powerful press. The meal is stacked into the form of a cheese, 2 or 2½ ft. square and 3 or 4 ft. high, consisting of layers of powder 1 to 2 in. thick, separated by plates of copper or vulcanite. The press reduces the bulk of the powder nearly one half, and delivers it in sheets five eighths of an inch to an inch thick, which, in hardness, lustre, and fracture, resemble thick slates. The degree of pressure to be given is one of the most important considerations in the process of manufacture; since the ultimate density of the powder is determined by it, and this in turn determines the rate of combustion. By merely varying the degree of pressure, the powder may be made either violently and destructively explosive, or mild and easy in its action. The press cakes are broken into grains by passing them through corning rolls, and the different sizes of grains are separated by passing the whole over a succession of sieves, with varying mesh. The grains thus obtained are sharply angular, and require rounding and smoothing to prevent their thin edges from being ground into dust by the wear of transportation and handling. While still moist, the powder (now granulated) is put into rolling-barrels, slowly revolved from 6 to 24 hours, and then withdrawn smooth, lustrous, and free from angularity. Sometimes the glazing is heightened by the addition of a minute quantity of graphite. A single tablespoonful of this substance will impart its peculiar lustre to half a ton of fine powder. Its presence has no appreciable effect upon the action of the powder, nor upon its preservation. The last operation, drying, takes place in a room heated by steam to 130° or 140° F.—Much progress has been made in the past 20 years in diminishing the destructive effects of gunpowder upon large cannon. A brief consideration of the relations between the pressure of a body of gas and the volume it occupies will readily indicate that the elastic force of gases generated by the combustion of gunpowder in a gun must be many times greater at the breech than at the muzzle; that is, greater in the earlier than in the latter stages of discharge. It is the maximum pressure which involves danger to the gun; and the principle upon which this progress has been based consists in keeping the maximum pressure well within the limit of safety, and increasing as far as possible all pressures below that limit. To accomplish this, advantage has been taken of the following properties: The combustion of a cartridge is not instantaneous, but progressive. It must first be ignited throughout, by flame from the vent, which diffuses itself through the interstices between grains, enveloping progressively the whole. Secondly, each grain must

burn progressively from its surface to its centre. It is obvious that the pressure due to any particular position of the shot will depend upon the total amount of gas developed; and hence, if we can retard the combustion in the initial and accelerate it in the terminal stages, we can, in part at least, accomplish the desired end. At all events, we can reduce the initial gas development in two ways: first, by diminishing the amount of surface presented for ignition by a given weight of powder, which is done simply by increasing the size of the grain; secondly, by decreasing the rate at which combustion progresses into each grain, which is done by increasing the density of the grains, and thus closing more tightly the pores through which ignition penetrates their mass. The effect of diminishing the initial pressure without a compensating increase of the terminal pressures would be a reduction of the velocity of the shot. This may be restored by an increase of the charge, which augments again the initial pressure, but not to such an extent as to carry it beyond the limit of safety. By increasing the size and density of the grains

the old method. A leading variety of these geometrical forms is the prismatic, in which the grains are hexagonal prisms, about an inch in length and diameter. Each prism is perforated with seven holes, one tenth of an inch in diameter, parallel to the axis. They are symmetrically packed into a cartridge, of very small bulk in proportion to its weight. This form of powder is used for large rifled (Krupp) guns in the Russian, Prussian, and Austrian service, and its performance is excellent. Short cylinders have been used by the English, but they have been supplanted recently by pebble powder. Lenticular powder (grains in the form of lenses) has been tried in this country, but with indifferent results. The central portions, as a necessary result of the mode of pressing, were much less dense than the peripheral, and therefore burned too rapidly. Grains which had been ignited in the gun and extinguished in the air, and collected afterward, showed that the middle portions only had been consumed, leaving a ring of the denser portions. Ritter prismatic powder is simply the prismatic form just described, but without the perforations; it has been used in Belgium only. In recent experiments under the United States government, pellets in the form of two truncated pyramids, having a common hexagonal base, have been employed; and the results appear to be better than those obtained by any other nation. The irregular, large-grained powder, used in heavy guns, receives the name mammoth powder in this country, and pebble powder in England; but these titles indicate no essential difference.—Gunpowder is classified, according to the size of the meshes through which the grain is sifted, into 11 numbers, from 0 to 10, the latter being the finest rifle powder, and the former the mammoth. In classifying it according to quality, each maker has his own method and nomenclature. In the United States government service it is classified into: 1, musket; 2, mortar; 3, cannon; 4, mammoth powder. Two sieves are used for separating the grains of each class, all the grains being required to pass through the larger, and none through the smaller. The sizes of the meshes in decimal parts of an inch are:

FIG. 1.—Forms of Gunpowder.

while increasing the charge, artillerymen have retained control of the energy of gunpowder, and at the same time have actually increased the velocities of even the largest projectiles. For instance, in 1864 the American 15-inch gun, when using 50 lbs. of powder and a shot of 450 lbs., showed a pressure of about 15,000 lbs. and an initial velocity of 1,100 ft. per second. At present (1874) the same gun and shot, with 120 lbs. of powder, give about 22,000 lbs. pressure and 1,730 ft. initial velocity. Another improvement consists in giving to the grains definite geometrical forms. The advantage of this modification results not so much from the form itself, as from the fact that the action of the individual grains is much more likely to be uniform. In the process of pressing the powder, by the methods which have been in use for many years, great irregularities of density always occur; and as the explosive property is more influenced by the density than by any other quality, the advantage of securing uniformity in this respect is manifest. Geometrical or "pellet" powder requires a mould for each grain, whereby the density can be regulated with far more precision than by

CLASS.	Large.	Small.
Musket .....	·06''	·03''
Mortar .....	·10	·06
Cannon .....	·85	·25
Mammoth .....	·90	·60

The density of granular powder is either the absolute density, which is that of the grains themselves, or the gravimetric density, which is that of a quantity of grains with their interstices. The absolute density ranges from 1·60 to 1·80, the most common figure being about 1·75. The gravimetric density is generally about equal to that of water.—Sporting powder is made with especial care, of the purest saltpetre and sulphur, and the most carefully

selected charcoal. The article is usually judged by the velocity it gives to a projectile, and the amount of fouling. In both respects erroneous judgments are likely to be formed, since the mode of charging is more frequently the cause of a poor performance than any defect in the quality of the powder. If a given brand is found to give a lower velocity than desired, it is better to increase the charge than to resort to a more violent kind; for the smaller charge is more apt to strain and erode the gun than the larger charge of milder powder. There is seldom any sufficient reason for excessive fouling, since this may generally be corrected by the use of a patch and lubricant.—The force of gunpowder is measured by an instrument called a pressure gauge. Three forms have been used, two of which were invented by Gen. Rodman of the United States ordnance department. One of these is applied to the exterior

FIG. 2.—Rodman's Internal Gunpowder Gauge.

*a a*, cylindrical steel box; *b b*, cover; *c*, steel piston rod; *d*, steel disk, carrying *e*, the indenting knife; *f*, disk of soft copper; *g*, copper cup for gas check; *h h*, copper washer.—The smaller figures show the parts *c*, *d*, *e*, and *f*, enlarged, and viewed from the side, and the indentation made on the copper disk.

of a gun, and communicates with the chamber by a narrow passage. The other is inserted in the cartridge bag at the base of the charge, and remains in the gun after the discharge. The internal gauge consists of a cylindrical box of steel, with a cover screwed on. Through the axis of the cover is a cylindrical hole, in which a steel rod is fitted. Within the box is a thick disk of steel, having a knife edge protruding from its lower face. This knife has a double shear, the edges of the two shears meeting at the centre in a very obtuse angle. At the bottom of the box the apex of the knife rests upon a disk of soft, annealed copper. The inner end of the steel rod is stepped into the steel knife disk, and its outer end is a little below the top of the cover. A copper cup rests upon the top of the rod, to serve as a gas check. The pressure of the explosion is received by the rod, which communicates it to

the knife, the apex of which sinks into the copper, giving a cut, the length of which serves as the measure of the pressure. The working parts of the external gauge are quite similar to the foregoing, but the manner of housing them is different. Another form of gauge, invented by Capt. Noble of the English artillery, substitutes for the copper disk a short cylinder of copper, which is crushed by the pressure, the amount of crushing being employed to measure the pressure. This gauge is screwed into the wall of the gun in such a manner that the end of the rod receiving the pressure is very near the surface of the bore. Both forms of gauge are liable to grave objections, since the measure obtained is essentially dynamical, while the quantity to be measured is statical. The English gauge is much inferior to the American, and cannot be relied upon to give even approximate indications of pressure when violent powder is used.—In the composition of blasting powder, nitrate of soda (Chili saltpetre) has of late years been chiefly used in the United States, instead of nitrate of potassa; the latter being subject to a high duty, while the former is duty-free. So far as explosive properties are concerned, the difference between the two is not very great; but the former absorbs moisture from the air and deliquesces, while the latter does not, unless the air be very damp and the exposure long continued. Hence nitrate of soda rapidly deteriorates, a matter of comparatively little importance in blasting powder, which is commonly used soon after manufacture. (For the constitution of other blasting powders, see EXPLOSIVES.) But as war material is frequently accumulated and stored, or transported long distances and more or less exposed, military powder must be made with nitrate of potassa. Powder for blasting differs essentially from military or sporting powder in the formation of CO instead of CO<sub>2</sub>, yielding the same volume of gaseous product for the same temperature, but less heat; hence a lower temperature of products, and consequently a lower immediate explosive energy. The combustion is also slower. The theory of its use has been to loosen the surrounding rocks to as great a distance as possible from the bore hole, and to waste as little force as possible in the hurling of fragments or the production of very small pieces, or dust. Usually a good deal of work with the pick and bar, and of subsequent breaking or blasting of large fragments, has accompanied the main blasting operations. The introduction of nitro-glycerine compounds has led to a change of practice; and many engineers now find a gain in the more complete shattering of the rocks by quick explosion, which permits an easier handling and a more rapid progress, besides, what is economically most important, the substitution of single-hand drills and small holes. Even rifle powder is now used in this way, it is said, with good results. The most judicious authorities appear to agree, however, that the nature of the rock

to be removed is an important element in the problem, and that the system which answers well in one mine is not necessarily the best in all. For quarries in which stones of certain shape and size are to be obtained, and for such coal mines as employ blasting, of course the shattering effects of charges are specially undesirable; and either small charges or slow-burning explosives must be preferred. The amount of ordinary blasting powder required to remove a cubic yard of rock in mining is exceedingly variable, depending upon the nature, structure, and tension of the rock, as well as the quality of the powder and the skill of the workman. This variety is illustrated by the following data, chiefly selected from the records of European experiments, as to the amount of powder required to remove one cubic yard of material:

SUBSTANCES.	Localities.	Powder, lbs.
Rock salt.....	Wieliczka, Austria....	0·05
" ".....	Dieuze, France.....	0·59
Coal.....	Waldenburg, Prussia..	0·02

An inspection of this table shows how greatly experience varies. It also appears that hardness is not the only quality involved in the resistance offered by rocks. Thus gypsum, which is one of the softest rocks, resists blasting by virtue of its lack of firmness and its elasticity. Native copper can scarcely be blasted at all, on account of its tenacity. (See BLASTING.)—The amount of capital and annual product of the gunpowder manufacture in the United States is reported by the ninth census (1870) as follows:

STATES.	Capital.	V lue of product.
California.....	\$573,000	\$526,427.
Connecticut.....	635,000	751,000
Delaware.....	1,400,000	727,500
Massachusetts.....	199,500	199,000
New York.....	270,000	547,519
Ohio.....	150,000	275,000
Pennsylvania.....	752,900	873,033
Tennessee.....	20,000	60,000
Wisconsin.....	20,000	82,000
Total.....	\$4,020,400	\$3,991,779

**GÜNS** (Hung. *Kőszeg*), a town of Hungary, in the county of Vas, on a river of its name, 57 m. S. S. W. of Presburg; pop. in 1870, 6,915. It contains a palace of Prince Esterházy, a Benedictine monastery, and several churches and educational establishments. Wool is largely manufactured, and there is considerable trade in wine and fruits, especially cherries. In 1532 it was besieged by Sultan Solymán the Magnificent, with 60,000 men, who made thirteen assaults on the fortifications, all of which were repulsed by a small Hungarian garrison, commanded by Nicholas Jurisich.

**GUN-SHOT WOUNDS**, injuries caused by the discharge or bursting of firearms. They are of two classes, according as the explosion of the powder does or does not carry solid projectiles. Slight wounds from powder alone are properly burns; but if the quantity of powder be large or in a confined space, serious contusions and lacerations may ensue. Not only the expansion of the liberated gases, but the unburned portions of powder, and the contact of surrounding bodies put in motion by the explosion, are to be considered in these complicated wounds, though their treatment is ordinarily the same as for burns, lacerations, and contusions from other causes. These wounds are purely mechanical, and are more dangerous in proportion to the contiguity to vital organs; an explosion from a pistol introduced into the mouth or near the thoracic or abdominal cavity might prove fatal, while the same on the back or limbs would be trifling. A wound from a musket ball in a fleshy part presents an opening of entrance smaller than the ball in most cases, and with livid and inverted edges, and the opening of exit, if there be such, larger, more ragged, and with everted edges; if the ball was fired very near, the entrance is larger than the exit. These facts often enable an expert to tell the direction and the distance from which a wound was received. The diminished velocity of the ball, its more rapid rotation on its axis, and its consequent more lacerating progress, explain the larger and more irregular opening of its exit. A slight obstacle is sufficient to divert a ball from its original direction, causing singular eccentricities in its course; a trifling obliquity of surface, or difference of density in the parts struck, may produce the most circuitous passage. A ball may enter on one side of the head, neck, chest, abdomen, or limb, and pass out on the other, having apparently passed directly through, whereas it has really passed entirely round. Spent balls cause injuries of great violence and with little apparent external wound. These cases were formerly attributed to the wind of the ball, from compression or displacement of air in its course; but it is now known that a ball after a certain period of its course acquires a rotary motion on its axis, the more rapid as its progress is nearly ended. If a ball with such a motion strike a part of the body, it does not pierce or carry it

away, but simply rolls over it like a wheel, crushing the unyielding and resisting tissues, without necessarily lacerating the skin; contusing the viscera, for instance, without opening the abdominal cavity. A ball in its course may meet and force into the body pieces of clothing, bone, or other foreign bodies, more mischievous than the original projectile. The pain of a gun-shot wound is dull and heavy, though in the excitement of battle it would be less noticed than a sabre or bayonet wound. The bleeding is generally less externally than would be supposed, unless a large artery be severed. The constitutional disturbance is great and peculiar. Paleness and coldness of surface, trembling and weakness of limbs, faintness, alarm, and confusion of mind, are more marked than in other kinds of wounds of equal severity. In common cases, inflammation comes on in the course of 24 hours, with swelling and stiffness, and pain; pus forms on the third or fourth day, and in the course of the next five days more or less of the parts torn by the ball slough away; this over, granulations form, the wound contracts, and heals in six or eight weeks, the lower opening closing first. In healthy persons the constitutional disturbance is neither great nor of long duration. In unhealthy constitutions inflammation runs high, the suppuration is profuse and obstinate, and the patient recovers with a disabled limb or an enfeebled body. If the ball or a foreign body carried with it enters a sensitive or vital part, there will be no safety until it comes away; but if it enters parts without much sensibility and presses upon no nerve, it may remain for years without inconvenience. Mortification of a limb after a gun-shot wound may arise from the severity of the wound, the excess of inflammation, or division of the large blood vessels. Another dangerous complication of these wounds is secondary hæmorrhage from excess of arterial action, separation of sloughs from arteries, ulceration of their coats, or general inflammatory exudation; this is most likely to occur in persons of sanguine temperament, when exposed to the depressing influences of hospital life. The prognosis in these wounds should be given with much reserve, as it is impossible in most cases to predict the exact result. If the thoracic and abdominal cavities or the joints are penetrated, or any important organ is wounded, with injury of large vessels or nerves, or comminuted fracture of bones, the danger of a fatal termination is great. But, apart from the battle field, there are instances of survival after great injuries of vital organs. Perhaps the most notable case is that of Alexis St. Martin, recorded by Dr. Beaumont. (See BEAUMONT, WILLIAM.) Among other cases are those of William Poole, a New York rough, who lived for some time with a ball lodged in the substance of the heart, and of Virginia Stewart, a woman of the town in the same city, who lingered for several days after a pistol bullet had passed through her

brain. The wounds made by conical rifle balls are attended with much laceration of soft parts and splintering of the bones.—The treatment of simple gun-shot wounds does not materially differ from that of lacerations and deep punctures. Cleansing of the openings, the arrest of hæmorrhage, stimulants and opiates, antiphlogistic and soothing applications, free exit of pus, and rest of the part, are the principal points to be attended to; if there is but one opening, search should be made, by dilatation if necessary, for the ball or other foreign body, which should be extracted if it is likely to prove inconvenient or dangerous; secondary hæmorrhage will require compression, cold, caustic, or the ligature, according to circumstances. In cases of severe laceration with splintering of bones, the question of primary or secondary amputation becomes one of the most difficult the surgeon has to decide.—In the “Medical and Surgical History of the War of the Rebellion,” published by the United States government in 1870, will be found the best collection of cases and illustrations of gun-shot wounds in any language.

**GUNTER, Edmund**, an English mathematician, born in Hertfordshire about 1581, died in London, Dec. 10, 1626. He was educated at Westminster school and at Christchurch college, Oxford, where he gave his attention principally to mathematics, and in 1606 invented the sector. Subsequently he took orders; but his tastes being altogether mathematical, he procured in 1619 the professorship of astronomy in Gresham college, which he filled until his death. His works, consisting of the *Canon Triangulorum*, “The Sector and Cross Staff,” &c., have been several times printed in a collective form, the best edition being that of 1673 (4to, London). His inventive faculty was very usefully exercised in the production of the chain, the logarithmic line, the quadrant, and the scale bearing his name, of which descriptions are subjoined.—**GUNTER'S CHAIN**, the chain employed in land surveying, is 66 feet or 4 rods in length, and is divided into 100 links, which are connected with each other by one, two, or three rings. The length of each link, together with half the length of the rings connecting it with the adjoining links, is 7·92 inches; every 10th link is marked by a tally of brass, for convenience in measuring, and part of the first link at each end is formed into a large ring for the purpose of holding it with the hand. Ten square chains, or 100,000 square links, make one acre.—**GUNTER'S LINE**, a logarithmic line, sometimes termed the line of lines or line of numbers, and usually graduated upon scales, sectors, &c., consists simply of logarithms graduated upon a ruler, thus serving to solve problems instrumentally, as logarithms do arithmetically. It is generally divided into 100 parts, every 10th division being numbered from 1 to 10. By means of this line the following problems can be solved: 1. To find the product of two numbers: the

space between division 1 and the multiplier is equal to the space between the multiplicand and the product, the distance in each case being laid off in the same direction. 2. To divide one number by another: the extent from the divisor to unity equals that from the dividend to the quotient. 3. To find a fourth proportional to three given numbers: the space between the first two numbers equals the distance from the third number to the required fourth proportional. 4. To find a mean proportional between any two given numbers: one half the distance between the lesser number in the left-hand part of the line, and the greater number in the right-hand part, will extend to the mean proportional sought, if applied forward from the lesser number, or backward from the greater. 5. To extract the square root of a number: one half of the distance between unity and the given number, if laid off from unity, will give the point representing the desired root. Similarly, the cube root or that of any higher power can be found, by dividing the distance between unity and the given number by the index of the root, the quotient giving the distance between unity and the point representing the root required.—GUNTER'S QUADRANT is usually made of wood or brass, and contains a kind of stereographic projection on the plane of the equinoctial, the eye being supposed in one of the poles. The tropic, ecliptic, and horizon form arcs of circles, but the hour circles are curves, delineated by means of several altitudes of the sun for some particular latitude every year. It can be used for the determination of time, the sun's azimuth, &c., and also for taking altitudes of any object in degrees.—GUNTER'S SCALE, generally termed by seamen the Gunter, is a large plain scale, generally 2 ft. long by about  $1\frac{1}{2}$  in. broad, and used in solving problems in navigation, trigonometry, &c. On one side of the scale are natural lines, and on the other the artificial or logarithmic ones; the former side contains a scale of inches and tenths, two plain diagonal scales, and various lines relating to trigonometry as performed by natural numbers.

GÜNTHER, Anton, a German philosopher, born in Lindenau, Bohemia, about 1785, died in Vienna, Feb. 24, 1863. He studied at the university of Prague, and, after passing several years as tutor, devoted himself to theology at the college of Raab, and in 1820 was ordained priest. He passed two years at a novitiate of the Jesuits, and then took up his residence at Vienna, where he was vice director in the university and imperial censor. He became eminent as a writer on philosophical subjects. But while he combated the views of Hegel and Herbart, and endeavored to reconcile the doctrines of the Catholic church with the teachings of modern philosophy, he blamed the fathers of the church for having employed pagan conceptions in seeking to impress the truths of religion. He incurred the disapprobation of the Jesuits, and was summoned to

Rome, but ill health prevented his going. His works (placed upon the *Index Expurgatorius* in 1857) include *Vorschule zur speculativen Theologie* (2 vols., 1828); *Peregrins Gastmahl* (1830); *Thomas à Serupulis* (1835); *Die Juste-Milieus in der deutschen Philosophie gegenwärtiger Zeit* (1838); *Der letzte Symboliker* (1844); and *Grundriss der Metaphysik* (1848).

GURJUN BALSAM. See supplement.

GURLEY, Ralph Randolph, an American clergyman and philanthropist, born at Lebanon, Conn., May 26, 1797, died in Washington, D. C., July 30, 1872. He graduated at Yale college in 1818, and soon after took up his residence in Washington. He was licensed to preach by the presbytery of Baltimore, but was never ordained. In 1822 he became agent of the American colonization society, a position which he retained until his death. He visited Africa in behalf of colonization three times, under appointment of the society or of the United States government, and aided in the organization of the Liberian government. He also visited England for the purpose of securing English aid for African colonization. During the first ten years of his agency the annual income of the colonization society increased from \$778 to \$40,000. He delivered speeches in its behalf in all parts of the country, edited the "African Repository," and besides many reports wrote "The Life of J. Ashmun" (Washington, 1835), "Mission to England for the American Colonization Society" (1841), and "Life and Eloquence of Rev. S. Larned" (New York, 1844).

GURNARD, an acanthopterous fish belonging to the family of *sceleroptera* or "mailed cheeks," characterized by a prolongation of the suborbital bones forward across the cheek, and immovably articulated behind with the preoperculum; the muzzle is also formed by a firm union of the frontal and other bones; and all these parts present a hard granulated appearance, often armed with spines. The gurnards belong to the genera *trigla* (Linn.) and *prionotus* (Cuv.), the latter being peculiar to America. In the genus *trigla*, in addition to the family characters, the body is scaly; there are two dorsal fins, the first spinous, the second flexible; the pectorals are moderate, and beneath them and at the base are three detached articulated rays on each side; branchiostegal rays seven; head of a parallelopiped form; teeth small and villiform on the jaws and pharyngeals; lateral line straight to the caudal, where it forks, variously armed with spiny scales. The gray gurnard or grunter (*T. gurnardus*, Linn.) grows to a length of 15 to 20 in., and rarely to 2 ft.; the body is more elongated and the snout longer than in most other species; the descending line of the profile is nearly straight; the snout is shovel-shaped, slightly emarginated, having on the top eight hard bony points; the head and shoulders granulated, and armed with spines; lateral line sharply serrated, and the dorsal scales

rough. The color above is gray clouded with brown, more or less spotted with black and yellowish white; below silvery. It is common on the English coasts, and is found from Norway to the Mediterranean; it keeps near the bottom, and feeds on crustaceans and mollusks, spawning in May and June; when taken

Gray Gurnard (*Trigla gurnardus*).

from the water it makes a kind of grunting sound (whence one of its common names), which cannot proceed from the air bladder, as this has no duct communicating externally. Notwithstanding its hideous appearance, its flesh is white, firm, and wholesome; it is caught in deep water, biting at almost everything, even a red rag. The habits of this fish are easily studied in the aquarium. They may be seen with their pectorals close to the sides, and with no motion of the tail, crawling along the bottom by means of the free pectoral rays, which are placed successively on the ground like so many feet; their light weight, rendered less by their capacious air bladder, is thus moved with considerable rapidity forward, backward, or sideways in search of food. These free rays are moved by a muscular apparatus independent of that supplying the common fin; to these rays are also distributed large nervous filaments, arising from a marked expansion of the upper part of the spinal cord, indicating that these organs are endowed with a delicate sense of touch. It stirs up the mud and sand with its shovel-shaped nose, and is enabled to detect its prey in the turbid water by means of these pectoral feelers. The large

Web-fingered Gurnard (*Prionotus palmipes*).

eyes, on the top of the head so as to catch all the rays of light, indicate an animal organized for living in comparative darkness.—The American gurnards of the genus *prionotus* are distinguished from those of the preceding genus

by the larger pectoral fins, and by the villiform teeth on the palate bones. The banded gurnard (*P. lineatus*, Mitch.) grows to a length of 12 to 18 in.; it is reddish brown above, covered with numerous black dots, and the abdomen white; the color of the dead fish above the lateral line is slaty, and beneath there are several brownish bands, whence its name; the head is covered with bony plates, rough, and armed with spines; the upper jaw the longer. It is found on the coast of Massachusetts and the middle states. It is called also grunter and sea robin. The web-fingered gurnard (*P. palmipes*, Storer), a much rarer species, grows to the length of about 18 in., and may be known by the dilated ends of the pectoral processes; the color is reddish brown above, with irregular darker shadings, and nearly white below. When alarmed, it buries itself in the sand by a rapid lateral movement of the body, leaving only the eyes and top of the head exposed; the flesh is occasionally eaten; it feeds principally on crustaceans. It is found from Massachusetts as far south as the Carolinas, and perhaps further. Other species are described.

**GURNEY**, Sir **Goldworthy**, an English inventor, born in Cornwall in 1793, died Feb. 28, 1875. He studied medicine, but gave his attention to chemistry, and in 1822 delivered a course of chemical lectures at the Surrey institution, which were published in 1823. He invented the Bude, oil vapor, lime, and magnesium lights, and claims to be the inventor of the oxyhydrogen blowpipe, and to have first produced the startings of the magnetic needle by cross currents from the voltaic battery, which form the basis of the electric telegraph. He also invented the high-pressure steam jet and the tubular boiler, and in July, 1829, drove a steam carriage on the turnpike from London to Bath at the rate of 14 m. an hour. His high-pressure steam jet, being applied to locomotives in October, 1830, increased the speed from 12 m. an hour to 30. It has since been used for the ventilation of coal mines and for extinguishing fires in them. In 1849 he applied it to the consumption of poisonous gases from a sewer in London. In 1852 he was appointed to superintend the lighting and ventilating of the new houses of parliament, for which he had invented a new method. In 1863 he became paralyzed. He resides at Reeds, Cornwall.

**GURNEY**, **Joseph John**, an English philanthropist, born at Earham hall, near Norwich, Aug. 2, 1788, died there, Jan. 4, 1847. He was educated at Oxford under a private tutor, without becoming connected with the university, and in 1818 became a minister of the society of Friends. At different times he travelled through Ireland, the United States and Canada (1837), and most of the countries of central Europe, to inquire into the condition of prisons. In these tours he was generally accompanied by his sister Mrs. Elizabeth Fry, and with her labored for the improvement of prison discipline. Much of his ample fortune was devoted to be-

nevolent purposes. He published "Notes on Prison Discipline" (1819); "Observations on the Religious Peculiarities of the Society of Friends" (1824); "Essays on the Evidences, Doctrines, and Practical Operations of Christianity" (1827); "Biblical Notes to confirm the Deity of Christ" (1830); "Accordance of Geological Discovery with Natural and Revealed Religion" (1835); "Sabbatical Verses" (1837); "Familiar Sketch of William Wilberforce" (1840); "A Winter in the West Indies, described in Familiar Letters to Henry Clay of Kentucky" (1840); and "Thoughts on Habit and Discipline" (2d ed., 1844). His memoirs, edited by Joseph Bevan Braithwaite, with selections from his journal and correspondence, were published in 1854 (2 vols. 8vo).

**GUROWSKI, Adam**, count, a Polish author and revolutionist, born at Rusocice in the palatinate of Kalisz, Sept. 10, 1805, died in Washington, D. C., May 4, 1866. Having been expelled in 1818, and again in 1819, from the gymnasia of Warsaw and Kalisz for revolutionary demonstrations, he continued his studies at different universities in Germany. He returned to Warsaw in 1825, and took part in the Polish insurrection of 1830. At its termination he took up his residence in Paris, where he was a member of the national Polish committee, and became conspicuous in political and literary circles. His estates had been confiscated by the Russian government, and he had been condemned to death; but in 1835 he published a work entitled *La vérité sur la Russie*, in which he advocated a union of the different branches of the Slavic race. The idea was regarded favorably by the Russian government, and Gurowski was recalled; and although his estates were not restored to him, he was employed in the civil service. In 1844 he became involved in a quarrel, and left Russia. He spent some time in Germany, and afterward in Switzerland, and for two years lectured on political economy in the university of Bern. He then went to Italy, and in 1849 came to the United States, where he engaged in literary pursuits, and became deeply interested in American politics. From 1861 to 1863 he was employed in the department of state at Washington. Before coming to America he had published *La civilisation et la Russie* (St. Petersburg, 1840); *Pensées sur l'avenir des Polonais* (Berlin, 1841); *Aus meinem Gedankenbuche* (Breslau, 1843); *Eine Tour durch Belgien* (Heidelberg, 1845); *Impressions et souvenirs* (Lausanne, 1846); *Die letzten Ereignisse in den drei Theilen des alten Polen* (Munich, 1846); and *Le Panславisme* (Florence, 1848). During his residence in the United States he published "Russia as It Is" (New York, 1854); "The Turkish Question" (1854); "A Year of the War" (1855); "America and Europe" (1857); "Slavery in History" (1860); and "My Diary," notes on the civil war (3 vols., 1862-'6).

**GURWHAL**, Gurhwal, or Gurwal, a N. W. district of British India, in the Northwest Prov-

inces, between lat. 30° and 31° 20' N., and lon. 78° and 79° 20' E., bounded N. and N. E. by the Himalayas, which separate it from Thibet; area, about 4,500 sq. m.; pop. in 1871, 309,947. It occupies the S. W. slope of the Himalayas, and includes some of the loftiest peaks of that range. Its surface presents little else than a succession of mountains and deep narrow valleys, among which rise several head streams of the Ganges. Only a small part of the country is cultivated or inhabited. Many of the hills are totally destitute of vegetation, and others are covered with low forests. The chief crop in the low regions is rice. Wheat, barley, buckwheat, battu or amaranthus, pulse of various kinds, oil seeds, the poppy, cotton, sugar cane, and tea are also cultivated. Field labor is performed by women. Horses are rare, asses are unknown, but cattle, sheep, and goats are carefully reared. The greater part of the inhabitants are Hindoos, the remainder being of Thibetan or of mixed Thibetan and Hindoo origin. They are below the middle size, have dark hair and beards, and a lighter complexion than the Hindoos of the plains. Their houses are built of layers of stone and squared beams, and are usually three stories high, the ground floor being occupied by the cattle.—Gurwhal was dependent on some of the more powerful hill states until the reign of Mohiput Shah, who declared himself independent and built Serinagur for his capital. Under the sovereigns of this dynasty the state embraced the district of the Dehra Doon, and about one half of Kumaon. In 1803 it was overrun and devastated by the Gorkhas, and in 1814 was wrested from the conquerors by the British and restored to the family of the former rajah.

**GURWOOD, John**, an English soldier, born in 1791, died by his own hand in Brighton, Dec. 25, 1845. He entered the British army as ensign in 1808. At the storming of Ciudad Rodrigo, in 1812, he led the forlorn hope, and received the sword of the governor on the surrender of the fortress. He served throughout the whole of that war, and was severely wounded at Waterloo. In 1831 he became private secretary to the duke of Wellington, and in 1841 was raised to the rank of colonel. In 1834 he commenced the publication of "The Despatches of Field Marshal the Duke of Wellington, during his various Campaigns in India, Denmark, Portugal, Spain, the Low Countries, and France, from 1799 to 1818," which extended to 13 vols. 8vo. In return for his services Col. Gurwood received from the duke the appointment of deputy governor of the tower of London. He committed suicide in a fit of insanity from the effects of a wound in the head received at Ciudad Rodrigo.

**GURYEV**, or Guriev, a town of Russia, in the government and 188 m. E. N. E. of the city of Astrakhan, capital of a circle of the same name, on an island of the Ural, not far from the Caspian sea; pop. in 1867, 2,838. It has

a jail, a river port, manufactories of cotton and linen, distilleries, and fisheries. The inhabitants are mostly Cossacks of the Ural.

**GUSTAVUS I.**, known as **GUSTAVUS VASA**, king of Sweden, born at the castle of Lindholm, May 12, 1496, died in Stockholm, Sept. 29, 1560. He was the son of Eric Johansson, a Swedish senator of the noble house of Vasa, and before his accession to the throne bore the surname of Ericsson. Both his parents were descendants of the ancient kings of Sweden. After having studied at the university of Upsal he entered the service of his kinsman the regent Sturé in 1514, at a period of intense civil commotion. Sweden, which by the compact of Calmar in 1397 became a dependency of Denmark, had declared her independence; but the nobility and clergy were much divided, and the young Gustavus was soon called on to bear arms with his patron against the archbishop Trollé, the leader of the Danish party. In 1517 a Danish army was sent to the archbishop's assistance; but the Swedes defeated it, and Gustavus distinguished himself in the battle. In the following year King Christian II. of Denmark took the field in person. After the Swedish victory of Brännkyrka, Gustavus and five other nobles were given up as hostages for the king's safety during a proposed interview with the regent; but having got them in his power, Christian carried them in chains to Copenhagen. After a year's detention Gustavus escaped, and spent eight months in Lübeck. While there he heard of the regent's defeat and death in battle, and the subjugation by the Danes of all Sweden, except the fortresses of Calmar and Stockholm. Bent upon the liberation of his country, he hastened to Calmar; but the garrison, composed of foreign mercenaries, had resolved to surrender, and he narrowly escaped with life. He then visited some of the southern provinces, and endeavored to rouse the peasants, but met with only threats and insults, and was many times in danger of being arrested. Meanwhile Christian had been acknowledged by the Swedes, and was crowned at Stockholm, Nov. 4, 1520. Four days afterward he caused a massacre of the nobles and populace, including the father of Gustavus. A price was set on the head of the latter, and death was threatened to whoever should assist him. Disguised in rags, he worked for some time as a miner and woodcutter in Dalecarlia, until, deeming the time ripe for his enterprise, he threw off concealment, and haranged the inhabitants. His eloquence, the sturdy patriotism of the Dalesmen, and their hatred for Christian, led 600 men to take up arms and proclaim him "lord and chieftain of the realm;" and in February, 1521, he made himself master of Kopparberg. The people of the coasts declared in his favor; the insurrection spread rapidly, and having defeated the Danes in the battle of Westerås, April 29, and taken several fortresses, he called an assembly of the

states at Wadstena in August, and received from the deputies an offer of the crown, which he refused for the title of administrator. His success from this time was almost uninterrupted, and he was soon acknowledged by most of the nobles and people. Christian threatened him with the death of his mother and two sisters, who were held prisoners at Copenhagen, if he did not disperse his followers; Gustavus refused, and the threat was carried into execution. At length Christian was deposed by his Danish subjects (April, 1523), and his partisans in Sweden gave in their adhesion to Vasa, who accepted the title of king at the diet of Strengnäs, June 7, and entered Stockholm in triumph two weeks afterward. While at Lübeck Gustavus had listened to Martin Luther; he had since corresponded with the reformer, and although he durst not begin his reign with an open profession of the new doctrines, his first measures were directed against the Roman Catholic clergy. Several insurrections were thus excited, which were easily put down. In 1527, at a meeting of the states at Westerås, the king obtained the exclusion of bishops from the senate and their formal subjection to the civil power. The ceremony of coronation, which he had deferred until now rather than take the oath to support the church, was performed at Upsal, Jan. 12, 1528, by the Lutheran archbishop Lars Petri. The reformation now made rapid progress in Sweden; and at a national council held at Örebro in 1529 Lutheranism was adopted as the state religion. Having thus, as he said, "conquered his kingdom a second time," Gustavus formed an alliance with Frederick I. of Denmark against the deposed Christian II., who, having secured the assistance of the emperor Charles V., entered Norway with an army in 1531, and was joined by a number of Swedish malcontents. The troops of Gustavus and Frederick soon forced him to surrender, and the ex-king passed the rest of his life in confinement. Meanwhile the domestic affairs of the kingdom called for the attention of Gustavus. The exactions of the nobles aroused an insurrection of the peasants (1537), who declared their intention "to destroy the nobility, root and branch." In 1542 the rising became general under the lead of Nils Dacke, an escaped criminal, who took the field with 10,000 men. Avoiding a pitched battle, and encouraged by the count palatine Frederick, who gave him a patent of nobility, by the emperor Charles V., and by the duke of Mecklenburg, Dacke held his ground till 1543, when he was killed and his followers dispersed. The disorders caused by the imprudence of the Lutheran pastors were checked, and Gustavus, having at last secured peace at home and abroad, and caused the crown to be declared hereditary in his family, devoted himself to administrative reform. In 1555 a war broke out with Russia, and was continued with varying success until the peace of Moscow, in April, 1557. The last years of the king's life were embittered by

domestic troubles, arising chiefly from the evil propensities of his son Eric. Gustavus was thrice married: first to Catharine of Saxe-Lauenburg, the mother of his son and successor Eric; secondly to Margaret de Laholm, the daughter of a Swedish noble; and thirdly to Catharine Stenbock, niece of Margaret.

**GUSTAVUS II., Adolphus**, king of Sweden, sixth of the line of Vasa, son of Charles IX. and Christina of Schleswig-Holstein, born in Stockholm, Dec. 9, 1594, killed at Lützen, Nov. 6 (new style 16), 1632. His father was the youngest son of Gustavus Vasa, and had been called to the throne on the exclusion of his nephew Sigismund, king of Poland, who was the rightful heir, but had given umbrage to the states by professing the Roman Catholic religion. (See CHARLES IX. of Sweden.) Sigismund had made an alliance with Russia for the recovery of the Swedish crown, and Gustavus Adolphus, on the death of his father, Oct. 30, 1611, inherited a war with the Poles and Russians, besides a long standing hostility with the Danes. Securing the assistance of his nobles by confirming their privileges, he made a peace with Denmark on favorable terms, and then, turning his arms against the Russians, drove them from Ingria, Karelia, and part of Livonia. He made a treaty with the czar at Stolbova in 1617, by which he retained much of the conquered territory, and was then in a condition to prosecute the Polish war with greater advantage. He overran the Baltic coast from Riga to Dantzic, made himself master of a large part of Polish Prussia, defeated the Poles in several engagements, but was repulsed and wounded before Dantzic, and on Sept. 30, 1627, fought a bloody but indecisive battle. The emperor Ferdinand II. now took part in the contest, placed Gustavus under the ban of the empire, and sent 10,000 men under Wallenstein into Pomerania. The Swedes, however, continued victorious, and by the mediation of France and England a truce for six years was concluded in September, 1629, on terms highly favorable to Gustavus. Meanwhile the expense of the war had raised several seditions at home, which the king put down by alternate mildness and severity. Leaving the care of his kingdom to the chancellor Oxenstiern, Gustavus now turned his attention to fresh foreign conquests. The growing power of Austria on the Baltic, the affront put upon him by Ferdinand in the late war, and the danger that threatened the Protestant cause in the great religious contest which then divided Germany, joined to an ambition to aggrandize his country, induced him to declare war against the emperor; and having presented to the states assembled at Stockholm his daughter Christina as the heiress of his throne, he set sail with about 20,000 men, and landed at the mouth of the Oder, June 24, 1630. By July 10 he had seized almost the whole of Pomerania. He levied a heavy contribution in this province, disciplined his troops, taught them a new system of tactics, and then, having

received an accession of six Scottish regiments under the duke of Hamilton, led a division of his army into Mecklenburg. Ferdinand, who at first looked with contempt upon the movements of this "king of snow," now proposed a truce; but Gustavus preferred to follow up his successes, and in eight months from the time of his landing he had taken 80 fortified places. The imperialists under Tilly and Pappenheim gained several successes, but many of the Austrian magazines fell into the hands of the Swedes, and Gustavus, having first carried Frankfort-on-the-Oder by assault, pushed on toward Magdeburg, which Tilly was then investing. Before he could reach it the city was stormed, and more than 25,000 of the inhabitants were massacred. In September, 1631, Gustavus was joined by the elector of Saxony, with whom he at once gave battle to Tilly, and defeated him at Breitenfeld, near Leipsic, Sept. 7. This signal victory over a general never vanquished before, which displayed the superiority of the king's mode of fighting, based on boldness of attack and celerity of movement, at once established his reputation as a general. The Protestant states now hailed him as their leader. The elector of Saxony carried the war into Bohemia, while Gustavus marched into Franconia and the Palatinate, defeated Tilly again at Würzburg, and wintered at Mentz. Oxenstiern would have had him attack Vienna, but Gustavus, anxious to appear not as a conqueror, but as the liberator of the Protestants, had resolved to confine the operations of his armies to the N. and W. provinces. Ferdinand now determined to recall Wallenstein, who had been dismissed about the time of the Swedish landing; but before he could obey the summons Gustavus had attacked the Austrians at the river Lech (April, 1632), and had driven them into Ingoldstadt. Tilly was mortally wounded in the action. Munich surrendered to the Swedes in May; almost the whole of Bavaria was in their hands, and the elector was forced to take refuge in Ratisbon. The Lutheran peasants of Upper Austria took up arms; the Swiss granted permission to the king to raise levies in their territory, and the Swedish standard was carried triumphantly by Bernhard of Saxe-Weimar to Lake Constance and the Tyrolean mountains. At this juncture Wallenstein appeared at the head of 40,000 men, drove the Saxons from Bohemia, entered Prague on May 4, effected a junction with the elector of Bavaria at Eger on June 11, and thence advanced toward Nuremberg, where he found Gustavus intrenched. The hostile armies remained in sight of each other for three months, each endeavoring to conquer by famine and disease. At last Gustavus, having made an unsuccessful attempt to storm the position of the enemy, retired toward the upper Danube, and in November entered Saxony, where Wallenstein was spreading carnage and desolation. On the 5th he found himself face to face with the enemy at Lützen, with 12,000 foot and

6,500 horse under his command; Wallenstein's army is believed by good authorities to have been considerably superior in numbers. The night was spent in preparation for battle. The morning of the 6th broke foggy, and when the mists rose, about 10 o'clock, the Swedes were seen kneeling in their ranks. They sang Luther's hymn, *Ein' feste Burg ist unser Gott*, and a hymn composed by the king, and then charged the enemy, Gustavus leading the right wing and Bernhard of Weimar the left. The imperialists were driven from their strong intrenchments, but meanwhile Pappenheim arrived with a body of cavalry from Halle, and the Swedes were turned back in confusion. Gustavus rallied them, and with a small body of horse rode forward to support the infantry in a fresh attack; but approaching too near a squadron of imperial cuirassiers, he received a shot in the arm, and as he turned to be led away another in the back which caused him to fall from the saddle. His horse, which had been wounded in the neck, dragged him some distance by the stirrup, and galloping riderless back to the ranks roused the Swedes to fury. Led by Bernhard of Weimar, they rushed forward with an impetuosity which nothing could resist. Pappenheim fell mortally wounded, and Wallenstein at last ordered a retreat. The dead body of the king was found covered with wounds. After having been embalmed at Weissenfels, it was carried to Stockholm, and there interred in the church of Riddarholms. It was believed that the duke of Saxe-Lauenburg, the king's cousin, who was with him when he fell, and a few days afterward went over to the Austrians, inflicted the wound in the back of which Gustavus died.—Gustavus inherited the commanding presence, eloquence, and accomplishments of his grandfather. He aimed at great conquests, but the extent of his ambition can hardly be conjectured. He owed his success in battle to strict discipline and the ardor with which he inspired his soldiers. His magnanimity, clemency to the vanquished, and respect for the religious opinions of others, compelled the esteem of his enemies. Though eminently a warlike king, he devoted much time to the internal affairs of Sweden; he encouraged commerce and manufactures, made excellent regulations for the mines, and endowed the university of Upsal. He is regarded as the Protestant hero of Germany, and in 1832, on the 200th anniversary of his death, was founded the "Gustavus Adolphus union." Up to the close of 1868 this society had expended about 2,325,000 thalers in the support of new and poor Protestant congregations. Gustavus was married in 1620 to Maria Eleonore of Brandenburg, whose court he had visited in disguise for the purpose of choosing a wife. Their daughter Christina was his successor.

**GUSTAVUS III.**, king of Sweden, eldest son and successor of King Adolphus Frederick and Ulrica Louisa, princess of Prussia, born in

Stockholm, Jan. 24, 1746, died there, March 29, 1792. He was educated under the superintendence of Counts Tessin and Scheffer. His ambitious tendencies early awakened the anxiety of these noblemen, who vainly attempted to restrain and correct his disposition. On his accession to the throne, Feb. 12, 1771, the state was divided between two sordid and corrupt factions. They were the "Hats" and "Caps," or "France and Commerce," against "Agriculture and Russia." Under Adolphus the Hats had obtained the predominance, and proposed to subvert the constitution by force, and to rescue the country from the domination of the nobles. Gustavus, who at the time of his father's death was travelling on the continent, procured from the French government a promise of aid and support against the aristocratic party. Hastening to Sweden, he labored to obtain popularity, while his emissaries propagated disaffection to the diet. Having matured his scheme, Gustavus confided the secret to a favorite officer, Hellichius, who shut the city gates of Christianstad, and published a manifesto against the diet. The place was immediately invested by government troops, while Stockholm was declared under martial law. Gustavus, having secured the support of the troops, posted a guard over the assembled senators, harangued the people on the great square, entered the hall with a strong guard, and produced a new constitution, which was immediately approved and confirmed by subscription and oath. The diet acquiesced; and thus, on Aug. 21, 1772, without the loss of a single life, a revolution was accomplished. The government he created was better than that of the oligarchy he had overthrown, though the royal power was increased. In 1783 he went abroad again, visited Italy, and passed some time in Paris. During his absence a famine made great havoc, the people were disturbed, the nobility rose against him, and the diet forced him to make concessions. The king, who in 1772 was the idol of the nation, had become in 1787 an object of detestation. War was now employed to stimulate loyalty. Gustavus secretly ordered a march upon St. Petersburg, and, having quelled an uprising of the nobles, secured extraordinary powers, and at the head of a body of Dalecarlian peasants repulsed the Danes who menaced Gothenburg, he began in person a vigorous campaign against Russia. The war continued with varying success for upward of two years, and was terminated by a peace on terms honorable to Gustavus after the Swedish naval victory of Swenkasund, July 9–10, 1790. Dissatisfied, however, with the result of the war, he resolved to take part in restoring the power of Louis XVI., and aimed at heading a Swedish, Russian, Prussian, and Austrian coalition for the invasion of France. He went to Spa and Aix-la-Chapelle to concert measures, but before his plans were matured he was shot at a *bal masqué* in Stockholm by Anckarstroem, the instrument of a conspiracy

of nobles. Gustavus lingered 18 days after receiving the fatal shot. He was a man of great ability, but capricious and insincere. He was the author of dramatic works and lyric poems, published in Swedish in Stockholm in 1806-'12 in 6 vols., and also in French. On June 23, 1788, before his departure for the Finnish war, he deposited two boxes in the library of Upsal, requesting that they should only be opened 50 years after his death. They were opened March 29, 1842, and found to contain historical and literary essays and letters, which were published by Geijer (3 vols., Upsal, 1843-'6), and translated into German.

**GUSTAVUS IV., Adolphus**, king of Sweden, only son of the preceding, born Nov. 1, 1778, proclaimed king March 29, 1792, died Feb. 7, 1837. He was declared of age on completing his 18th year, Nov. 1, 1796. He had been betrothed at an early age to a princess of Mecklenburg, but Catharine II. of Russia planned a marriage for him with her granddaughter Alexandra. Gustavus accepted an invitation to visit the imperial court, and was received with splendid hospitality. The princess possessed great beauty and wit, and he fell in love with her. The marriage was about to be solemnized, and the empress upon her throne, the court collected in state, and the young bride all awaited the appearance of the groom. At the latest hour he had been permitted to examine the marriage contract, and found that it pledged him to declare war against France, and to permit his queen to remain in the Greek church. He forthwith rejected the alliance, returned immediately to Stockholm, and became next year the husband of the princess Friederike of Baden, from whom he was divorced in 1812. With the czar Paul, who succeeded Catharine, he negotiated the renewal of the armed neutrality. After the murder of Paul, his successor Alexander lost no time in making peace with England. Gustavus and Alexander alone among the sovereigns of Europe protested against the execution of the duke d'Enghien; and in the Germanic diet, in which Gustavus as duke of Pomerania had a voice, he inveighed boldly against the French emperor. Napoleon replied in the *Moniteur*, reproaching Gustavus with having deserted the Danes, and satirizing the young king as the heir of Charles XII. only in "jack boots and audacity of tongue." Gustavus had early assumed the dress and professed to imitate the spirit of Charles. The French minister was peremptorily dismissed from Stockholm, and French newspapers were forbidden the kingdom. The king soon after took the field in person against Bernadotte, who occupied Hanover with 30,000 troops. Austerlitz and the peace of Presburg obliged him to retreat, and the campaign was confined to unimportant skirmishes in Prussia. The peace of Tilsit was forced upon Russia and Prussia; and Gustavus alone upon the continent of Europe held out against the French empire. Napoleon at-

tempted to dazzle the young king with visions of Norway; but his overtures were rejected, and Gustavus was driven across the Baltic. Robbed of Pomerania, he was now to be despoiled of Finland. Napoleon and Alexander having come to an understanding at Erfurt for the partition of Sweden, Caulaincourt announced to his diplomatic colleagues at St. Petersburg that "Gustavus IV. had ceased to reign." Supported by England with a subsidy for one year of £1,200,000, and the assurance of auxiliary troops, Sweden presented a bold front. A Russian army overran Finland; but Gustavus quarrelled with Sir John Moore, who had come to his assistance with 10,000 English troops; he forbade their landing, and the English general returned home in disgust. With more than 100,000 Swedes under arms, Gustavus managed never to have 10,000 together; and these he exhausted in continued forced marches, now threatening a descent upon Denmark, now upon Norway, and again hurrying across the whole breadth of Sweden to renew the war in Finland. The English minister was instructed to release Sweden from her English obligations, if she should find her necessities such as to render concessions inevitable. In return, Gustavus, without consulting his cabinet, sent a despatch to Gothenburg subjecting the British shipping in that harbor to an embargo. Next morning he recalled the order, and offered a renewal of alliance with England on the same subsidiary basis. His mismanagement was long attributed by the people to the incapacity of his council; but the truth could not be always concealed; his insanity was apparent, and his deposition was evidently necessary. A plot soon took form and order, and it was resolved by a band of resolute nobles to offer the crown to the English duke of Gloucester. The offer was made, but not accepted. A body of troops marched upon Stockholm, and Baron Adlercreutz accepted the charge of arresting the king, who was imprisoned in the castle of Gripsholm, while his uncle, the former regent, was placed at the head of affairs, with the title of protector, but was soon after elected king as Charles XIII. Gustavus in the mean while resolved to anticipate the decree of dethronement by abdication, which he did in a document dated March 29, 1809. The diet assembled, solemnly renounced allegiance, and declared the heirs of his body for ever excluded from the throne. The exiled family proceeded, about eight months after the king's arrest, in a Swedish frigate to Germany, Gustavus having assumed the title of count of Gottorp. The Swedish government settled upon him a pension equivalent to \$26,000. Charles XIV. (Bernadotte) subsequently obtained from the diet authority to adjust equitably all money affairs between Sweden and the exiled Vasa family, and paid over to the Russian emperor, the brother-in-law of Gustavus and the guardian of his children (the father having separated himself from his wife and family),

the value of his private estates, about \$600,000, which was transmitted as a private fortune. In 1810 Gustavus visited England, where he lived at Hampton Court, and found companionship among the royal exiles of France. In 1812 he went to Denmark, where he assumed for a time the title of duke of Holstein. He subsequently wandered about Europe, often in great need, for he proudly refused the Swedish pension. His wife and children often devised means of secretly placing in his way what appeared to be necessary for his support. During the later years of his life he appeared in threadbare garments, seeming to glory in privations and poverty. He became a resident of the canton of Basel, and died at length in a humble abode at St. Gall. In 1828 his son Gustavus (born Nov. 9, 1799) ineffectually memorialized the courts of Europe in support of his claim to the title of prince of Sweden, and, upon the death of his father, to the style and dignity of king. The claim was again publicly renewed in 1859, on the death of King Oscar.

**GÜSTROW**, a town of Germany, in the grand duchy of Mecklenburg-Schwerin, on the Nebel, and on a branch of the Schwerin and Rostock railway, 22 m. S. of Rostock; pop. in 1871, 10,575. It has several churches, among them a cathedral built in the 13th century, a former castle which is now a state workhouse, a gymnasium and other literary institutions, a hospital, manufactories of tobacco and machines, iron foundries, tanneries, and breweries. Horse races and cattle shows are held annually.

**GUTENBERG, Johann**, or **Henne**, the reputed inventor of printing, born in Mentz, Germany, about 1400, died there, Feb. 24, 1468. His father's name was Gensfleisch or Gänzfleisch, Gutenberg being the name of his mother, or that of an estate which belonged to the family. His family was of noble lineage, and he occupied a respectable position in his native city, from which, however, civic dissensions caused him with many others to migrate in 1420. He became a citizen of Strasburg, where he appears to have devoted many years to mechanical experiments of various kinds. In 1436 he entered into a contract with Andrew Dritzehn and others of that city for the purpose of practising in partnership, and for the common benefit, all his secret and wonderful arts. Three years later he was sued by the brother of Dritzehn, who had died in the interval, for money due the latter by the terms of his contract; and in the course of the trial it was shown that among the wonderful arts which Gutenberg was to reveal to his associates was printing, and that as early as 1438 he was in possession of a press, movable types, forms, and other appliances of the art. As he never affixed his name to the title pages of his books, it is not certain that he produced any printed works at Strasburg. After 1444 all trace of him is lost till 1448, when he was again in Mentz. In August, 1450, he entered into a partnership with Johann Faust of Mentz for the purpose of carrying on

the business of printing, the latter undertaking to furnish the funds. The partnership terminated at the end of five years, Faust having in a suit for moneys advanced obtained possession of most of the materials of the business. With such as remained to him Gutenberg established himself in the house *zum Gutenberg*, belonging to his mother, where he appears to have carried on printing with considerable activity, and to have associated himself with a Doctor Conrad Homery, who afterward came into possession of the stock. In 1465 Gutenberg abandoned printing, and entered the service of the elector Adolphus of Nassau as a gentleman of the court, with a suitable compensation. The number and character of the works printed by him, or with his coöperation, have afforded a fruitful subject of controversy, and by many it has been maintained that his merit was altogether that of an experimenter. In his own and in modern times he has to a certain extent been obliged to share with Faust and Peter Schöffer the credit of his invention; and so obscure are many passages of his history that his name has almost been considered a myth. Schöffer in several instances publicly claimed the invention for himself, and also for his father-in-law Faust; but in the preface to a German translation of Livy, published in Mentz in 1505, it is distinctly stated by his son Johann Schöffer that the "admirable art of printing was invented in Mentz in 1450 by the ingenious Johann Gutenberg, and was subsequently improved and handed down to posterity by the capital and labor of Johann Faust and Peter Schöffer." The testimony of his contemporaries and the opinion of most modern writers seem to agree, however, that Gutenberg not merely invented the art, but practised it for many years previous to his death, and long before he became associated with Faust. Zell, a contemporary writer, mentions a *Catholicon*, and one or more editions of the Donatus, possibly printed at Strasburg, of the former of which no copy remains. Another *Catholicon*, called the *Catholicon Joannis Jannuensis*, was published by Gutenberg in Mentz in 1460. During the partnership with Faust appeared the "Letters of Indulgence," the "Appeal against the Turks," and the well known Mazarin Bible, their joint production; and of the celebrated Psalter, published by Faust and Schöffer in August, 1457, within 18 months after the separation from Gutenberg, and containing their imprint, much of the work was undoubtedly done by the latter. In addition to these, the "Calendar for 1457," the *Hermann de Saldis Speculum Sacerdotis*, published about 1457, and the *Celebratio Missarum*, have been ascribed to him, although Dr. Dibdin thinks very doubtfully of the two latter, as well as of the Donatuses, and is inclined to consider the *Catholicon* of 1460 and the "Vocabularies" of 1467-'9 more genuine specimens of his press or of the types used by him. The other works sometimes ascribed to Gutenberg

are of very doubtful authenticity. In 1540, a century after the invention of printing, the city of Wittenberg first publicly celebrated the event. The example was followed in the succeeding century by Strasburg, Breslau, and Jena, and many cities of Germany have since held centennial jubilees in honor of Gutenberg and his invention. In 1837 a statue of him in bronze by Thorwaldsen was erected in his native place, and in 1840 Strasburg, the birth-place of the art, inaugurated with great pomp one by David d'Angers.—The chief authorities on the life of Gutenberg are: *Essai d'annales de la vie de Gutenberg*, by J. G. Oberlin (Strasburg, 1801); *Essai sur les monuments typographiques de Gutenberg* (Mentz, 1802), and other works, by M. G. Fischer; *Éloge historique de Jean Gutenberg*, by Née de la Rochelle (Paris, 1811); *De l'origine et des débuts de l'imprimerie en Europe*, by Auguste Bernard (2 vols., Paris, 1853); *Essai historique de Gutenberg*, by J. P. Gama (Paris, 1857); and Lamartine's memoir, *Gutenberg l'inventeur de l'imprimerie* (12mo, Paris, 1853). See also an article giving a summary of the facts and the arguments which the life and works of Gutenberg have evolved, by Ambrose Firmin-Didot, in the *Nouvelle biographie générale*.

**GUTHRIE**, a S. W. county of Iowa, drained by the middle fork of Raccoon river; area, 576 sq. m.; pop. in 1870, 7,061. The soil is fertile. The Chicago, Rock Island, and Pacific railroad intersects the S. part. The chief productions in 1870 were 164,012 bushels of wheat, 447,380 of Indian corn, 73,827 of oats, 12,873 of potatoes, 120,390 lbs. of butter, 35,180 of wool, and 10,405 tons of hay. There were 2,692 horses, 2,077 milch cows, 3,552 other cattle, 9,480 sheep, and 8,599 swine; 3 saw mills, and 2 woollen factories. Capital, Panora.

**GUTHRIE, Thomas**, a Scottish clergyman, born at Brechin, Forfarshire, July 12, 1803, died at St. Leonards, Fifeshire, Feb. 24, 1873. He was educated at Edinburgh, and was licensed to preach in 1825. He afterward studied medicine in Paris, and on his return to Scotland was for a time employed in his father's banking house. In 1830 he was ordained pastor at Arbirlot near Arbroath, and in 1837 was transferred to the old Greyfriars church, Edinburgh. Here he became very popular among all classes, exerted himself to reach the masses of the people, and opened the old Magdalene chapel in the Cowgate, giving the poor residents of the neighborhood the preference in seats. Greyfriars was a collegiate church, and in 1840 the separate parish of St. John's was erected for him. The new building was arranged with especial reference to the wants of the poor, but was hardly occupied when in 1843 the disruption of the church of Scotland took place. In the discussions which led to that event Dr. Guthrie had taken a prominent part, and he now coöperated with Chalmers, Candlish, and Cunningham in the organization of the Free church. In 1845 the work of building manses

throughout the church was put under his care. For some time after the disruption his congregation met in a Methodist chapel, but subsequently St. John's Free church was built for him. He sought to open in the basement of his church a ragged school, but being opposed by the elders of the congregation he undertook a larger work, apart from the supervision of any particular church or denomination. About this time he published his "Plea for Ragged Schools," which was many times republished, and his ragged school became the pioneer of many like schools. He was also active in the temperance reform. In 1848 he was obliged on account of impaired health to have a colleague, and Dr. William Hanna was chosen to the place. In 1864 Dr. Guthrie was forced to give up public speaking, retired from the pastorate, and became editor of the "Sunday Magazine," then just starting. In October, 1872, he was again prostrated by sickness, and in February, 1873, went to St. Leonards in the hope of relief, but a fatal attack almost immediately ensued. Dr. Guthrie was remarkably eloquent both as a pulpit and platform speaker. He published about 20 volumes, mostly collections from his sermons, or republications from "Good Words" and the "Sunday Magazine." Among the most famous of these are "The Gospel in Ezekiel," "The Saint's Inheritance," "The Way to Life," "On the Parables," "Out of Harness," "Speaking to the Heart," "Studies of Character," "The City and Ragged Schools," "Man and the Gospel," and "Our Father's Business." His works have been republished in America, including his "Autobiography and Memoir," by his sons (1874).

**GUTHRIE, William**, a Scottish author, born in Brechin about 1708, died in London in 1770. He studied at Aberdeen, and for some time was a schoolmaster, then went to London and became an author and compiler, and from 1746 was pensioned by government. His most important works are: "General History of England" (3 vols. fol., London, 1744-'50); "General History of Scotland" (10 vols. 8vo, 1767-'8); "General History of the World" (12 vols. 8vo, 1764-'7); a "Peerage;" and a "Geographical, Historical, and Commercial Grammar," of which numerous editions in all sizes appeared, the 1st in 1770, the 24th in 1827, 4to. Among his other works is "The Friends, a Sentimental History" (2 vols. 12mo, 1754).

**GUTS-MUTHS, Johann Christoph Friedrich**, founder of the German system of gymnastics (*Turnwesen*), born in Quedlinburg, Aug. 9, 1759, died at Schnepfenthal, May 21, 1839. In 1779 he entered the university of Halle, where he passed three years in the study of theology. In 1786 he was employed to superintend the gymnastic exercises of the Schnepfenthal institute. He published *Gymnastik für die Jugend* (Schnepfenthal, 1793); *Spiele zur Übung und Erholung des Körpers und Geistes für die Jugend* (1796); *Kleines Lehrbuch der Schwimmkunst* (Weimar, 1798); *Turnbuch für die*

*Söhne des Vaterlands* (Frankfort, 1817); *Handbuch der Geographie für Lehrer* (Leipsic, 1810); and *Methodik der Geographie* (1835).

**GUTTA PERCHA** (Malay, *gutta*, gum, and *percha*, the name of a tree), an inspissated juice called *gutta taban* by the Malays, the name being misapplied by the English. The tree which produces the gum was referred by Sir W. J. Hooker in 1847 to the natural order *sapotaceæ* and Dr. Wight's new genus *isonandra*, and named the *isonandra gutta*. It was formerly abundant in the forests along the foot of the hills in the Malayan peninsula, but the natives by cutting down the trees to procure the juice exterminated the plant, and the supply now comes from Borneo and other islands of the Indian archipelago. It is a large tree, commonly 3 to 4, but sometimes 6 ft. in diameter, with a straight trunk and reaching the height of 60 or 70 ft. The branches are numerous and ascending, and crowded with leaves at their extremi-

Gutta Percha (*Isonandra gutta*).

ties; these are petiolate, oblong, 4 or 5 in. long and 2 wide, of bright green above and brownish beneath. The flowers are small and white. The wood is peculiarly soft, fibrous, and spongy, pale colored, and traversed by longitudinal receptacles filled with the gum, forming ebony-black lines. To the Malays the valuable properties of the juice of the tree were known long before the Europeans became acquainted with the article. The natives found that the gum would become soft and plastic in hot water, and, being then moulded into any form, would retain this when cold. They made it into basins, vases, shoes, elastic sticks, whips, handles for *parangs* or axes, &c. The attention of Europeans was first called to it in 1842 by Dr. William Montgomerie, assistant surgeon to the residency at Singapore; and in 1843 Dr. D'Almeida of the same place brought specimens of the gum to England and laid them before the royal Asiatic society. They attracted little

attention till further communications from Dr. Montgomerie established the importance of the article by showing its applicability to the same uses as caoutchouc, and to others besides, and also the low cost at which the material could be procured in the greatest abundance. In 1844 a shipment of 2 cwt. was made from Singapore as an experiment, and soon after the product suddenly became a commercial article of importance. In 1847 Dr. Oxley published an interesting account of the tree and its product in a Singapore journal, describing the uses to which he had applied the gum for surgical instruments. He stated that the large trees which were formerly very abundant on the island of Singapore had been nearly all cut down by the natives, who adopted this destructive method of obtaining the juice, and who had sacrificed by his estimation 69,180 trees to procure one tenth this number of piculs, which was the exportation from Jan. 1, 1845, to July, 1847. The custom of tapping has since been introduced. The sap soon coagulates after it is collected, or it is made to do so by boiling, and is then kneaded by hand into oblong masses, 7 to 12 in. long and 4 or 5 broad. Its dark reddish brown color is derived from the impurities, as bits of the bark, that have accidentally fallen into the juice, or from sawdust and other substances introduced as adulterants.—Purified gutta percha has a brownish red color and a density of 0.979. It is a non-conductor of electricity, and by friction with almost any other substance (gun cotton and collodion are exceptions) it develops negative electricity. At ordinary temperatures it has considerable tenacity, being nearly as strong as leather, but much less flexible. When heated to 115° F. it becomes pasty, and between this and 140° or 150° it may be moulded into various shapes or drawn out into wires or tubes. It is insoluble in water, and slightly soluble in anhydrous alcohol and anhydrous ether, but soluble in boiling olive oil, from which it is deposited on cooling. Benzine, sulphide of carbon, chloroform, and oil of turpentine dissolve it with the aid of heat. It is insoluble in alkaline solutions or hydrochloric and hydrofluoric acids, and therefore may be advantageously used as a material for vessels to contain these liquids. Strong sulphuric acid carbonizes it, and nitric acid oxidizes it, converting it to a yellow resin. Gutta percha is remarkably porous. If a thin film be deposited upon a plate of glass or porcelain from its solution in sulphide of carbon, when examined with the microscope it will be found full of minute pores. When subjected to traction it becomes fibrous, and will then resist a much greater force without extension. Pure gutta percha is a hydrocarbon, having the formula  $C_{26}H_{32}$ . When exposed to light and air it slowly absorbs oxygen, and is converted into a white resin, having the composition  $C_{26}H_{32}O_2$ , and a yellow,  $C_{26}H_{32}O$ , both of which are soluble in boiling alcohol. The purified commercial article usually con-

tains from 75 to 82 per cent. of pure gutta, the remainder being composed of the two resins just mentioned.—The treatment of gutta percha is similar to that already described under *CAOUTCHOUC*. The first process is to purify it of the foreign substances, as earth, stones, and sticks, with which it is contaminated. For this purpose the blocks are sliced, by knives attached to powerful wheels, into shavings. These are introduced into a large tank of water heated by escape steam to boiling. The gum softens and runs together, and by the boiling most of the impurities separate and subside. The mass is then removed to a machine called a teaser, which is a large box containing a drum armed with rows of crooked teeth. This, revolving rapidly, tears the gum into shreds, which fall into a vessel of water, in which it floats, and the remaining impurities subside. The purified fragments are again boiled; they again run into a soft mass, and this is taken into the kneading or masticating machine, which is a strong cast-iron box containing a revolving cast-iron drum armed with strong iron teeth; or instead of the drum, two parallel rollers with screws on their surface are employed. Steam is let into the machine, and the gutta percha, kept soft by its heat, is thoroughly kneaded and brought to uniform consistency without air or water in the mass. It is then ready to be rolled into sheets or pressed into tubes; the former in their various sizes and thicknesses furnish the article in shapes convenient of application to most of the uses to which it is adapted. Tubes are produced by forcing the kneaded mass through a steel cylinder which terminates in a mould with a circular metallic core. Passing through this, the soft substance is prevented from collapsing by being drawn through a long channel of water by the revolution of a drum at the other extremity of the canal. By continually supplying the material the tubes are made without interruption; and in this way a single length has been produced of 1,000 ft. These tubes by their remarkable strength are well adapted for resisting great pressures; they are used for aqueducts, for feed pipes of steam engines, for hose, pump barrels, and various other purposes connected with the conveyance of water, gases, and vapors. The first machinery built for the coating of telegraph wire with gutta percha was in the autumn of 1848, at the works of the American gutta percha company in Brooklyn. The first order for the prepared wire was for the Morse telegraph company, and it was laid across the Hudson river at Fort Lee in August, 1849. The gutta percha employed was prepared with the greatest care to insure its purity. The raspings, rolled and then macerated in hot water, were washed in cold water, and then, being softened by boiling water, were driven by hydraulic apparatus through cylinders, in the end of which were wire-gauze sieves. After this the substance was thoroughly masticated and

kneaded, by which it was entirely deprived of moisture and rendered homogeneous and compact; and it was then introduced into the long horizontal cylinders kept hot by steam, and powerfully compressed by screw pistons worked by machinery. As it was forced out at the extremity the gutta percha was made to pass through a die, in which the strand of copper wires was introduced, and the whole was drawn along by a revolving drum upon which it was wound. A second and third layer of gutta percha were added to the core by repetitions of the process. Mr. Charles Goodyear applied the same process to moulding various articles in gutta percha, attaching the moulds, which were of metal in several pieces securely bolted together, to the end of the cylinder, through which the plastic gum was forced. Holes were left for the escape of the air in the moulds, and the appearance of the gutta percha at these indicated the completion of the filling.—Gutta percha is often used in combination with caoutchouc, the latter serving to soften and render the material more pliable and elastic, and less liable to be affected by changes of temperature. Both are alike affected by the treatment called vulcanizing, which is thoroughly mixing the gum with sulphur or some of its compounds, and then subjecting the mixture to an elevated temperature in close vessels. (See *CAOUTCHOUC*.) The methods and materials employed for vulcanizing gutta percha are numerous, and the object desired is not always the same. A hard horny material is produced under the patent of Mr. Stephen Moulton, by mixing the gum with hyposulphite of lead and adding more or less of calcined magnesia, and then subjecting the compound to a temperature of 250° to 300° for some hours. Mr. Hancock in his patent of 1847 employed a mixture of 48 parts of gutta percha with 6 parts of sulphuret of antimony, sulphuret of calcium, or some other similar sulphuret, and 1 part of sulphur. Mr. Emory Rider of London in 1856 patented an improvement which consisted in the addition of 1 part of litharge to 66 parts of gutta percha, together with 1 part of sulphur, or its equivalent in some of its compounds. These substances are mixed and well incorporated into the plastic gum by the action of heated rollers, which, revolving at different speeds, powerfully wear and grind the material; after which, in a close metallic vessel one third filled, it is subjected to the vulcanizing temperature for a few hours. The patents for mixing gutta percha with other substances are too numerous to be particularly noticed; even these substances are almost innumerable. The object of these various mixtures is to produce materials of different degrees of hardness and of different capacities of resistance to changes of temperature and other causes of change, but which may still be moulded into and retain the form of useful articles. The principal use of gutta percha is for covering telegraph cables. It is also used by den-

tists for taking impressions of the teeth and gums, and sometimes for a temporary filling for cavities. Baths and other articles for chemical laboratories, as funnels and tubing, may also be advantageously made of it. Many articles sold under the name of gutta percha are compositions of caoutchouc with other substances.

**GUTZKOW, Karl Ferdinand**, a German author, born in Berlin, March 17, 1811, died near Frankfort, Dec. 16, 1878. While at the university, he published in 1831 *Forum der Journalliteratur*. His next work was a novel, *Maha Guru, Geschichte eines Gottes* (1833). He became associated as a journalist with W. Menzel at Stuttgart, and published *Novellen* (2 vols., 1834), and *Soiréen und Oeffentliche Charaktere* (1835). His drama *Nero*, his preface to Schleiermacher's letters on Friedrich von Schlegel, and his novel *Wally, die Zweiflerin*, all appearing in 1835, confirmed his reputation as the head of "Young Germany." For the last named work (which was reprinted in 1852 under the title *Vergangene Tage*) he was imprisoned for three months at Mannheim, his former friend Menzel and other influential writers denouncing the tendency of his writings as inimical to religion and society. While in prison he wrote *Zur Philosophie der Geschichte* (1836), in opposition to Hegelianism, and next went to Frankfort, where he was married. To elude the censorship, he published *Die Zeitgenossen* (2 vols., 1837, subsequently included in his works under the title *Säkularbilder*) under the name of Bulwer; and in order to enjoy greater literary freedom he removed to Hamburg in 1838. Here he wrote, besides others, one of his most characteristic humorous and satirical novels in the vein of Jean Paul Richter, *Blasedow und seine Söhne* (3 vols., 1838-'9) and *Börne's Leben* (1840). Here he also opened a new era in the German drama by his tragedy *Richard Savage* (1840) and by many other plays, including his most popular comedies, *Zopf und Schwerdt* (1844) and *Das Urbild des Tartufe* (1847), and his most admired tragedy, *Uriel Acosta* (1847). He edited the *Telegraph für Deutschland* till 1842, when, after a visit to Paris, which he described in his *Briefe aus Paris* (2 vols., 1842), he left Hamburg to supervise at Frankfort a complete edition of his works (12 vols., 1845-'6). In 1847 he succeeded Tieck as dramatist at the Dresden theatre, and from 1852 to 1862 he edited at Frankfort the weekly journal *Unterhaltungen am häuslichen Herd*. His fame as the foremost German novelist of his day was established by *Die Ritter vom Geiste* (9 vols., 1850-'52), *Die Diakonissin* (1855), *Der Zauberer von Rom* (9 vols., 1859-'61), and *Die kleine Narrenwelt* (3 vols., 1856). In 1862 he became chief secretary of the Schiller institution at Weimar. In 1864 he made an attempt on his life at Friedberg, near Giessen, in a fit of insanity, from which he recovered after a time, and resumed his literary activity by the publication of various works, including the novel

*Hohenschwangau* (3 vols., 1868); *Lebensbilder* (3 vols., 1870-'72); *Die Söhne Pestalozzis* (3 vols., 1870), the plot of which is connected with the story of Kaspar Hauser; *Fritz Ellrodt* (3 vols., 1872); *Rückblicke auf mein Leben*, a reply to his critics (1875), &c.

**GÜTZLAFF, Karl**, a German missionary, born in Pyritz, Pomerania, July 8, 1803, died in Victoria, Hong Kong, Aug. 9, 1851. He was born of poor parents, and was apprenticed to a belt maker at Stettin. A sonnet which he addressed to the king of Prussia led to his being admitted as a student into the missionary institute at Berlin. His first appointment was from the Dutch missionary society at Rotterdam, which sent him to Batavia in 1826. There he married a rich English lady, and during the two years that he remained in Java he mastered the Chinese language. He then determined to go on his own account to China. Happening in the summer of 1828 to fall in with an English missionary named Tomlin, stationed in Siam, he went with him to Bangkok, where he stayed three years learning the Siamese language, and assisting Tomlin to translate the New Testament into that tongue. Proceeding thence to China, he fixed his residence at Macao, where he coöperated with Morrison, Medhurst, and others, in their missionary labors, he being now in communion with the Anglican church. In 1831-'3 he made extensive observations along the coasts of China, Siam, Corea, and the Loo Choo islands, first in the disguise of a Chinaman, and afterward as interpreter and surgeon on board the British ship *Lord Amherst*. On the death of Dr. Morrison, in 1834, Gützlaff was invited to succeed him as interpreter to the British superintendency. The difficulties that had grown up between the Chinese and British had obstructed the progress of the missions. The circulation of works in the Chinese character was forbidden, and the missionaries were compelled to remove their presses to Singapore. Afterward he was appointed secretary to the British plenipotentiary, and finally superintendent of trade, which office he held till his death. In 1844 he originated a society, ostensibly Chinese, for the purpose of carrying Christianity into the interior through the medium of native agents, and in 1849 visited Europe in behalf of the project. Besides translating Biblical works into various Asiatic languages, he wrote in English, "History of the Chinese Empire" (London, 1834), "China Opened" (1838), a "Journal of three Voyages along the Coast of China" (1831-'3), and a "Life of Tao-Kuang" (1851); in Chinese, "Pro and Contra;" in German, *Allgemeine Länder- und Völkerkunde* (Ningpo, 1843), *Geschichte des chinesischen Reiches* (Stuttgart, 1847), &c.

**GUY, Seymour Joseph**. See supplement.

**GUY, Thomas**, an English philanthropist, born at Horsleydown in 1643, died in London, Dec. 17, 1724. In 1660 he was apprenticed to a bookseller in London, and after his apprentice-

ship commenced business with a capital of £200. Being very parsimonious, he rapidly accumulated a fortune. He farmed the privilege of printing Bibles from Oxford university, and during Queen Anne's wars bought government securities at a depreciated rate. He also made large sums by buying South sea stock. He had engaged to marry a favorite servant maid, but for some trifling offence he broke his engagement and repudiated her. From this period he determined to lead a life of celibacy, and to devote his property to eleemosynary purposes. The erection of the hospital at Southwark which bears his name cost £18,793, and the sum which he left for its endowment amounted to £219,499. He also built an almshouse at Tamworth in Staffordshire, for 14 poor men and women, and bequeathed to it £125 a year; while to Christ's hospital, London, he left an annuity of £400 for ever. Esteemed an avaricious and selfish man by his contemporaries, he yet dedicated more money to charitable objects than any other private individual on record in England. He also left £80,000 to be divided among those proving any degree of relationship to him.

**GUYON, Jeanne Marie Bouvier de la Motte**, a French mystical writer, born in Montargis, April 13, 1648, died in Blois, June 9, 1717. She was the daughter of Claude Bouvier, seigneur de La Motte Vergouville, and early displayed a religious turn of mind, which was fostered by her parents, although they would not permit her to enter a convent. In 1664 she was married to Jacques Guyon, a man of uncongenial temper and 22 years her senior; but she succeeded at length in converting him to her religious views. Five children were born of this union, two of whom died young. M. Guyon died in 1676, and in 1680 Mme. Guyon removed to Paris, where she devoted herself to the education of her children and to charitable labors. She went to Geneva for religious work, and later to Gex. Here she became intimately acquainted with a priest named Lacombe, who restored her cheerfulness at a time of religious depression, and who was appointed by the bishop to be her spiritual director, but was in fact wholly subjected to her influence. The peculiar views on sanctification and other doctrines advanced by them soon brought them under suspicion of heresy, and in 1684 both she and Lacombe were ordered by the bishop to leave his diocese. She went then successively to Turin, Grenoble, Marseilles, Nice, Genoa, Vercelli, and Grenoble again, where her instructions proved very attractive, but exposed her to persecution. During these journeys she composed her "Spiritual Torrents" and "Short and Easy Method of Prayer," and began her commentaries on the Bible. In 1686 she returned to Paris, where she spent some time in comparative retirement. She was sought out, however, by multitudes of persons, among whom were many of high rank. With the duchess de Beauvilliers, the

duchess de Béthune, and the countess de Guiche, she organized meetings of ladies of rank for prayer and religious conversation. The duke de Beauvilliers and the duke and duchess de Chevreuse were among her disciples. Shortly before this the writings of Miguel de Molinos, the originator of the party called "quietists," had been condemned at Rome as heretical, and it was soon perceived that the teachings of Mme. Guyon were but little different from his. A vigorous movement was begun for their suppression, under the leadership of Mme. Guyon's half brother La Motte, a Barnabite priest. The first step was the imprisonment in the Bastille of Lacombe, whose preaching was producing extraordinary effect, and this was soon followed by the arrest of Mme. Guyon herself by royal order, and her confinement in the convent of Ste. Marie (January, 1688); but at the end of eight months she was released through the intercession of Mme. de Maintenon. Soon after this she met Fénelon, who became deeply engaged in her instructions, while she was equally interested that he might be brought to her own views. Mme. de Maintenon was likewise fascinated with her, and permitted her to disseminate her opinions at the female seminary of St. Cyr. At the suggestion of a brother of Boileau she wrote an apology for the "Method of Prayer," which renewed the outcry against her. A royal commission, of which Bossuet and Fénelon were both members, examined her writings, and a few passages were marked out as erroneous. To this decision Mme. Guyon submitted; but Bossuet wrote a treatise against her "Method of Prayer," which embodied severe reflections upon her character and conduct. It was the refusal of Fénelon to lend his signature to this work which led to the rupture between the two illustrious prelates. (See FÉNELON.) Meanwhile Mme. Guyon was imprisoned at Vincennes, in the Bastille, and subsequently at Vaugirard. In order, it is said, to prejudice the court of Rome against Fénelon, whose "Maxims of the Saints," a treatise designed to favor Mme. Guyon's doctrines, was then under examination by the pope, a letter was obtained from Lacombe, imprisoned at Vincennes, in which he exhorted Mme. Guyon to repent of their criminal intimacy. There is no doubt that the intellect of the enthusiast had been impaired by his confinement, and in fact he died insane not long afterward. Nevertheless, Mme. Guyon was sent back to the Bastille, her son was dismissed from the army, and some of her friends were banished. Her virtue, however, was acknowledged in the assembly of the French clergy at St. Germain in 1700, and in 1702 she was released from prison and banished to Diziers, where and in the neighboring city of Blois she passed the rest of her life in perfect retirement, professing on her deathbed an unhesitating faith in the Roman Catholic church and all its dogmas. The heresies of

which she was suspected consisted mainly in her doctrine of sanctification by faith, and of that complete identification of the will with the will of God which quietists call the "fixed" or "continuous state," and which is fully described in the "Spiritual Guide" of Molinos. She charged her opponents with having interpolated passages in her works and forged several writings which bore her name. Her principal works are: *Moyen court et très-facile pour l'oraison* (Lyons, 1688-'90); *Les torrents spirituels*, first printed in an edition of her *Opuscules spirituels* (Cologne, 1704); *Les livres de l'Ancien et du Nouveau Testament, traduits en français, avec des explications et des réflexions qui regardent la vie intérieure* (20 vols. 8vo, Cologne, 1713-'15); *Discours chrétiens et spirituels* (1716); *Lettres chrétiennes*, &c. (4 vols. 8vo, 1717); collections of hymns, &c.; and her autobiography, written during her imprisonment, and published after her death (*Vie de Madame Guyon, écrite par elle-même*, 3 vols. 12mo, Cologne, 1720). This work is silent upon some of the most important incidents of her life, and it has been supposed that it was written by Poiret from her papers. Many of her hymns were translated by Cowper.—See Upham's "Life and Religious Opinions and Experience of Madame de la Motte Guyon" (2 vols. 12mo, New York, 1847).

**GUYOT, Arnold Henry**, an American geographer, born near Neuchâtel, Switzerland, Sept. 28, 1807. He studied at Neuchâtel, Stuttgart, and Carlsruhe, where he formed an intimate friendship with Agassiz, and began with him the study of natural science. He afterward studied theology for three years at Neuchâtel and Berlin; but he was gradually led to devote himself to physics, meteorology, chemistry, mineralogy, zoölogy, and botany. In 1835 he went to Paris, where he resided five years, passing the winters in study and the summers in scientific excursions through France, Belgium, Holland, and Italy. In a tour of Switzerland in 1838, he first discovered the laminated structure of the ice in glaciers, the motion of the central portion being more rapid than that of the borders, as in streams of water. He showed that the motion of the glacier is due to the displacement of its molecules. These discoveries were fully confirmed and illustrated by the investigations of Agassiz, Forbes, and others, several years afterward. He next investigated the distribution of erratic boulders, in order to solve the question of the mode of their transportation. De Saussure, Von Buch, Escher, and Charpentier had made numerous observations on this subject, but the extent and true limits of these great outpourings of rocks from the bosom of the Alps were not accurately known. During seven successive summers Guyot traced them on both sides of the central Alps, in Switzerland and Italy, over a surface 300 m. long and 200 m. wide, and delineated eleven different regions of rocks. Their vertical limits and the laws of their descent were

determined by means of more than 3,000 barometrical observations; and the characteristic species of rock of each basin were tracked step by step to their source. The full details of these investigations were announced to form the second volume of the *Système glaciaire* by Agassiz, Guyot, and Desor, the first volume of which was printed in Paris in 1848; but political disturbances and the removal of Guyot to the United States prevented its publication. A topographical map of the subaqueous basin of the lake of Neuchâtel, believed to be the first of the kind ever published, was his next work. Guyot was professor of history and physical geography in the academy of Neuchâtel from 1839 to 1848. He then removed to the United States, and resided for several years at Cambridge, Mass., occasionally delivering lectures on his favorite subjects. He delivered in Boston in the winter of 1848-'9, in the French language, a course of lectures on the relations between physical geography and history, afterward translated and collected into a volume under the title of "Earth and Man." He was now employed by the Massachusetts board of education to deliver lectures in the normal schools of the state and before the teachers' institutes, and by the Smithsonian institution to organize a system of meteorological observations, for which he prepared an extensive series of practical tables. He was the first to determine the true height of Mt. Washington, in 1851; of the Black mountains of North Carolina, in 1856; and of the Green mountains of Vermont, in 1857. By these investigations he ascertained that there are more than 20 peaks in the Black and Smoky ranges higher than Mt. Washington. In 1855 he was appointed professor of physical geography in the college of New Jersey at Princeton, which post he still retains. In 1873 the Vienna international exhibition gave him a medal of progress for his geographical works. He read a paper on "Cosmogony and the Bible" before the meeting of the evangelical alliance in New York in 1873, embodying the substance of a course of lectures previously delivered in the Union theological seminary in New York. He has also published "Directions for Meteorological Tables" (Washington, 1850); "Geographical Series, Primary Geography" (New York, 1866; almost immediately republished under the title "Introduction to Geography"); "Intermediate Geography" (1870); and "Physical Geography," with a set of wall maps (1873). He has delivered lectures on "The Unity of the System of Life, the true Foundation of the Classification of Plants and Animals," in Brooklyn, N. Y., and before the Smithsonian institution in Washington, and on "Man Primeval," in the Union theological seminary in New York.

**GUYSBOROUGH**, an E. county of Nova Scotia, Canada, bordering N. E. on the gut of Canso and Chedabueto bay, and S. E. on the Atlantic; area, 1,656 sq. m.; pop. in 1871, 16,555, of whom 5,348 were of Scotch, 4,000 of Irish,

3,575 of English, and 1,190 of French origin. It is intersected by the St. Mary's and other rivers, and the coast is indented by numerous inlets. The fisheries are important, and gold mining is carried on at several points. Along the coast the land is rocky and barren, but in the interior there are some excellent farming tracts. Capital, Guysborough.

**GUYTON DE MORVEAU, Louis Bernard**, a French chemist, born in Dijon, Jan. 4, 1737, died in Paris, Jan. 2, 1816. While yet a minor he was appointed deputy attorney general at the parliament of Dijon, which post he held till 1782. He devoted his leisure to scientific pursuits, and procured the establishment at the academy of Dijon in 1774 of public lectures upon various branches of natural philosophy, and himself undertook the professorship of chemistry. In conjunction with Maret and Durande, he published in 1777 *Éléments de chimie théorique et pratique*, and also published annotated translations of several treatises of Bergman, Scheele, and Black. As early as 1773 he had used chlorine as a general disinfecting agent, and made the results of his experience known in his *Traité des moyens de désinfecter l'air* (1801). He suggested in 1782 the plan of a new chemical nomenclature, which was at once adopted by Lavoisier and others, who, in conjunction with him, perfected the original idea and reduced it to the shape it still retains. Meanwhile Guyton wrote the *Dictionnaire de chimie* for the *Encyclopédie méthodique*. In 1791 he was elected deputy to the legislative assembly, and afterward to the convention, where he voted for the death of Louis XVI. He was among the promoters of the polytechnic school, in which he was subsequently professor and director. He was administrator of the mint from 1800 to 1814, and favored the decimal system.

**GUZERAT**, or *Gujerat* (Hindoo, *Gurjara Rashtra*), a large district of India, in the province of Bombay, between lat. 20° 45' and 24° 45' N., and lon. 69° and 74° 20' E., bounded N. by the gulf of Cutch and Rajpootana, E. by Candesh and Malwa, S. by several British collectorates, the gulf of Cambay, and the Arabian sea, and W. by Cutch and the sea; area, 41,536 sq. m.; pop. estimated at 3,000,000. It comprehends the peninsula of Cattywar, the dominions of the guicowar, and several petty native states. The Western Ghauts form its E. boundary as far N. as lat. 21° 28', when they turn eastward. The W. extremities of the Sautpoora and Vindhya mountains extend a short distance into the province. The central regions are level and open. The principal rivers are the Subbermuttee, Mhyee, Nerbudda, Taptee, and western Bunnass. The mineral resources are small, and confined chiefly to iron and fine carnelians. The lion, tiger, leopard, wolf, hyæna, antelope, deer, nylgau, camel, and buffalo are common. The staple crop is cotton, which occupies about one half of the tilled land. Rice is much cultivated, and wheat, barley, bajra (the princi-

pal food of the poorer classes), gram, &c., are abundant. The inhabitants comprise Hindoos, Mahrattas, Rajpoots, Parsees, Coolies, Koonbies (an agricultural tribe), Dunjas (who subsist chiefly by the chase and fishing), Catties (who predominate in Cattywar), Jains, Bheels, Charuns, and Bhats. Among the principal towns are Baroda, Dongurpoor, and Cambay. —Guzerat formed part of the Mohammedan empire of Delhi, and, after having been separated from it during the Toghluks dynasty, was reannexed by Akbar in 1572, and remained a dependency till 1724. The Mahratta peishwa and the guicowar held large possessions in Guzerat, but the authority of the latter only is now recognized, the peishwa's territory having been ceded to the British.

**GWALIOR**, or *Gualior*. **I.** A part of India until lately nominally independent, but now subsidiary to the British, bordering on the North-west Provinces, Bombay, &c. It stretches very irregularly between lat. 21° and 26° 40' N., and lon. 73° 40' and 77° E.; area, 33,119 sq. m.; pop. about 3,250,000. The surface of the country in the north is level, in the centre hilly, and in the south rises into the Vindhya and Satpoora mountains. The Chumbul river bounds it on the N. W.; other rivers are the Sind, Betwah, and Dussam, flowing generally N. into the Jumna. S. of the mountains the Nerbudda and Taptee flow W. The soil is generally very fertile. The climate in the elevated S. part is mild and healthful. In January and February the thermometer falls three or four degrees below the freezing point; in the summer it sometimes rises to 100°. The most important product of the country is opium, which is delivered by treaty at a certain price to the British authorities. Burhanpoor in the south is the chief manufacturing town, where fine muslin scarfs, gold thread, glass, and paper are made. Other chief places are Gwalior, Oojein, Mundisoer, Hindia, and Chunderee. — This state was founded after the successes obtained by the Mahrattas over the Mogul forces in 1738 by Ranojee Sindia, a chief who raised himself from obscurity to eminence. His natural son Madhaji Sindia, who succeeded him, was an able and ambitious man, who greatly enlarged the possessions of the family, and in 1782, by the treaty of Salbye, concluded between the East India company and the peishwa, was recognized as a sovereign prince (maharajah). He maintained a large and well appointed army, organized and disciplined by French officers; and possessed himself of Delhi, Agra, and the person of the Mogul emperor, in whose name he subsequently acted. His dominions extended to the river Taptee on the south, and from the Ganges on the east to the gulf of Cambay on the west. His successor, Dowlt Row, became involved in war with the British, by whom his armies were totally defeated in 1803, and a considerable part of his territories taken from him, and he ceased to control the person of the Great Mogul. He

died in 1827, and was succeeded by Mugut Row, on whose death without children in 1843 the country fell into confusion and anarchy, which led to the interposition of the British; they restored order, and established the authority of the legitimate sovereign, Bhagerut Row Sindia, a boy eight years of age, who attained his majority in 1853. By a treaty concluded Jan. 13, 1844, it was stipulated that Sindia might maintain a military force not exceeding 9,000 men. Besides this, he was bound to maintain and pay about an equal number of the sepoys organized and commanded by British officers. The last body was termed the Gwalior contingent, and was mainly stationed at the fortress of Gwalior. During the sepoy mutiny in 1857 it joined in the revolt, murdered or put to flight its European officers, and demanded that Sindia should lead them against the British at Agra. The maharajah, however, remained faithful to the British, and

covered with blue porcelain tiles. Gunpowder and fireworks are made here, and there are cannon foundries. The rock, on the summit of which the fortress is built, is of sandstone, capped in some places with basalt. The face is perpendicular, and in some places the upper part overhangs the lower. The greatest length of the rock from N. E. to S. W. is  $1\frac{1}{2}$  m., the greatest breadth 300 yards. The height where it is greatest at the N. end is 342 ft. On the E. face several colossal figures are sculptured in bold relief. The entrance to the fortress is toward the N. end of the E. side: first, by means of a steep road, and higher up by steps cut in the face of the rock, of such a size and inclination that elephants can ascend them. This staircase is protected on the outer side by a massive stone wall, and is swept by several cannon pointing down it. The passage to the interior is through a succession of seven gates. The fort contains a palace and two remarkable

Gwalior.

exerted himself to prevent the contingent from taking the field; but in May, 1858, the mutineers commanded by Tantia Topee and Row Sahib, nephew of Nana Sahib, having been defeated and hard pressed by Sir Hugh Rose at Calpee, suddenly marched upon Gwalior, intending to make it a place of refuge. Sindia met them with his native troops a few miles from Gwalior, and gave them battle, June 1, but was deserted, and fled to Agra. The mutineers made Row Sahib maharajah of Gwalior. Sir Hugh Rose, however, shortly after reinstated Sindia. **II.** A city, capital of the district, in lat.  $26^{\circ} 13' N.$ , lon.  $78^{\circ} 15' E.$ , 65 m. S. of Agra, and 175 m. S. by E. of Delhi; pop. about 30,000. It stands at the foot of a high rock crowned by the fortress, and contains the tomb of Mohammed Ghous, a famous saint of the time of the emperor Akbar, a very beautiful building of white sandstone, with a cupola

pyramidal buildings of red stone in the most ancient style of Hindoo architecture. The fortress of Gwalior was built in 773 by Surya Sena, rajah of the adjacent territory. In 1023 it was unsuccessfully besieged by Mahmoud of Ghuznee. After many sieges and passing through various hands, it was taken by stratagem by Baber in 1526. Subsequently Akbar made it a state prison. After the dismemberment of the empire of Delhi it fell into the hands of the Sindia family, from whom it was taken by the English in 1780. It was recovered by

Sindia in 1784, was again taken by the British in 1803, and again restored in 1805, and from 1844 garrisoned by the Gwalior contingent under British officers.

**GWILT, Joseph**, an English architect, born in Southwark, Jan. 11, 1784, died at Henley, Sept. 14, 1863. His principal architectural works are Markham castle near Sligo, and Charlton church, near Woolwich. He published *Notitia Architectonica Italiana* (1818), a translation of Vitruvius (1826), and an "Encyclopædia of Architecture" (1842), and edited Nicholson's "Principles of Architecture" (1848).

**GWINNETT**, a N. county of Georgia, bounded N. W. by the Chattahoochee river, and drained by head streams of the Appalachee, Yellow, and Ulcofauchee; area, 550 sq. m.; pop. in 1870, 12,431, of whom 2,159 were colored. It is traversed by the Atlanta and Richmond Air-Line railroad. It is rich in minerals, in-

cluding gold, which is found on the Chatahoochee, iron, antimony, and superior granite. The surface is hilly and the soil of the river bottoms fertile. The chief productions in 1870 were 55,102 bushels of wheat, 206,210 of Indian corn, 31,707 of oats, 16,964 of sweet potatoes, 65,787 lbs. of butter, and 1,391 bales of cotton. There were 1,058 horses, 1,855 milch cows, 2,789 other cattle, 6,115 sheep, and 8,496 swine. Capital, Lawrenceville.

**GWINNETT, Batton**, one of the signers of the Declaration of Independence, born in England about 1732, died in Georgia, May 27, 1777. He emigrated from Bristol to America in 1770, engaged for two years in trade in Charleston, and then purchased a tract of land on St. Catharine's island, Georgia, and devoted himself to agriculture. He became conspicuous in 1775 as an advocate of colonial rights, was elected a representative to congress in February, 1776, and in 1777 became president of the provincial council of Georgia. He planned a military expedition against East Florida, which he refused to intrust to his rival Gen. McIntosh, whose official rank entitled him to command it, and which resulted disastrously. This event led to a duel between him and Gen. McIntosh, in which he was mortally wounded.

**GWYNN, or Gwinn, Eleanor**, one of the mistresses of Charles II., born in London about 1650, died there about 1690. It is said that her father, Capt. Thomas Gwynn of the army, was a member of an ancient Welsh family; but that she was born in a night cellar in the Coal Yard, Drury Lane, and was reared in the lowest haunts of vice. She was an orange vender, and wandered from tavern to tavern, entertaining the company with her songs. After being the mistress successively of the actors Hart and Lacy, she went in her 16th year upon the stage, and became one of the most popular actresses of the time in light, humorous parts, especially where singing and dancing were introduced. About 1667 she became the mistress of Lord Buckhurst, who, it is said, for a political reward, surrendered her to his royal master. She remained on the stage till 1671, although her intimacy with Charles, which lasted till his death, commenced in 1669. Upon becoming his acknowledged mistress she was called Madam Ellen, had an establishment of her own, and was even made a lady of the privy chamber to Queen Catharine, and admitted to the best society of the period. The king at first refused her demand of £500 a year, although she is said subsequently to have cost him upward of £60,000 in four years. Of all his mistresses Nell was the only one who remained faithful to him, and the only one perhaps who has won any sympathy or forgiveness from posterity. Her frailty and a tendency to hard swearing seem to have been her chief faults. She was merry and open-hearted, generous to profusion, and in her prosperity ever mindful of her old friends, particularly those of the theatrical profession.

Dryden, Lee, Otway, and Butler are reported to have been liberally aided by her. She instigated Charles to erect Chelsea hospital for disabled soldiers, presenting the land on which the building stands, and her health used regularly to be drunk by the pensioners on the anniversary of Charles's birthday. She was even popular with the public, as the supposed representative at court of Protestant interests. Charles appreciated her good qualities, and among his last words were, "Let not poor Nelly starve." She bore him two sons, one of whom died in childhood, and the other was successively created a baron, an earl, and finally duke of St. Albans. She is believed to have led a virtuous life after the death of the king, and her funeral sermon was preached by Dr. Tension, afterward archbishop of Canterbury. The "Memoirs of the Life of Nell Gwynn, Mistress to K. Charles II., by John Seymour, Comedian" (1752), is a panegyric. Another memoir, by Peter Cunningham, was published in 1850.

**GYGES**, the first Lydian king of the dynasty of the Mermnadæ. He was originally a chief officer at the court of his predecessor Candaules. According to Herodotus, Candaules was proud of the beauty of his queen, and insisted that Gyges should conceal himself in her chamber in order to see her naked. Gyges reluctantly obeyed, and was seen by the queen as he glided from her apartment. She was indignant at this insult, and sending for Gyges gave him the choice of being immediately put to death or of killing her husband. Gyges chose the latter alternative, and after slaying his sovereign he shared the Lydian throne with his former mistress. His reign commenced about 716 B. C., and lasted 38 years. The wealth of Gyges, like that of his successor Cræsus, was proverbial. He sent magnificent presents to Delphi, and carried on wars with Miletus, Smyrna, Colophon, Magnesia, and other cities of Asia Minor.—According to a story recorded by Plato, Gyges was the shepherd of Candaules, and found in an earthquake gap a great brazen horse containing a corpse with a golden ring, by means of which he could render himself invisible at will. With this power he destroyed Candaules and usurped his throne.

**GYMNASIUM** (Gr. *γυμνάσιον*, naked), a term applied anciently in Greece and Italy, and now in continental Europe, and especially in Germany, to schools of a higher class, but in England and America to places for physical exercise. The Greek gymnasium was so called because of the preëminence given in Greece to physical culture. The education of a Greek youth was divided into three parts, grammar, music, and gymnastics; to which Aristotle added a fourth, drawing or painting. Gymnastics, however, occupied as much time as all the others together, and were continued after the mental education was finished. There was no Greek town of importance without its gymnasium, and Athens had three: the academy, famous for the instructions of Plato;

the lyceum, where Aristotle taught; and the cynosarges. A gymnasium is described by Vitruvius, which is believed to have been at Naples, and which illustrates the general construction of gymnasia in Greece and Italy. It consisted of four porticoes placed in a square 1,200 ft. in circumference; three of them arranged with seats for philosophical and rhetorical conversation, while the fourth, a double portico, contained a large hall in the centre and rooms for the bath, anointing, and other purposes. In the winter gymnastic exercises were carried on in the shelter of the portico, and there were also sheltered and covered walks for study. The laws of Solon regulated the use of the gymnasium with great strictness, and a gymnasiarch or governor of the gymnasium was appointed with power to remove any teacher, philosopher, or sophist whom he thought injurious to the youth. The teacher of gymnastics was expected to know the physiological effect of the different exercises, and to assign to each pupil such as were suitable for him. The gymnasia were dedicated to Apollo, the god of physicians, because of their relation to health and disease.—In Germany the gymnasia occupy a middle place between elementary schools and the universities. The classics, mathematics, physics, and German literature are taught in them.

**GYMNASTICS** (Gr. *γυμναστική*, gymnastic art), a system of exercises which develop and invigorate the body, particularly the muscular system. If properly directed, gymnastics will enlarge and strengthen the various muscles of the trunk, neck, arms, and legs, will expand the chest so as to facilitate the play of the lungs, will render the joints supple, and will impart to the person grace, ease, and steadiness of carriage, combined with strength, elasticity, and quickness of movement; but an injudicious mode of exercise will frequently confirm and aggravate those physical imperfections for which a remedy is sought, by developing the muscular system unequally. Though athletic feats were at first performed by each individual according to his own notions, and were encouraged among the youth as combining amusement with exercise, they were at length reduced to a system, which in Greece formed a prominent feature in the state regulations for education; and as the nature of the warlike weapons rendered the development of physical force a subject of the highest military importance, athletic sports were continued during manhood. Public games were also consecrated to the gods, and were conducted with the greatest ceremony. The earliest mention we can find of gymnastic sports is in Homer's *Iliad*, book ii., where the Greeks are described as contending at javelin throwing and quoits; and again in book xxiii., when Achilles instituted games in honor of Patroclus, and distributed prizes to the victors for boxing, wrestling, throwing the quoit, chariot racing, &c. Plato tells us that just before

the time of Hippocrates gymnastics were made a part of medical study, as being suitable to counteract the effects of indolence and luxurious feeding, and that at length they became a state matter, reduced to a system and superintended by state officers. The first public gymnasia were built by the Lacedæmonians. These were imitated at Athens; where, in the walks belonging to one of them called the *Academia*, Plato instructed his pupils, and in another, named the *Lyceum*, Aristotle taught. At Athens a chief officer (*γυμνασιάρχης*) superintended the whole establishment; the *ἐπιστάτης* superintended only the most athletic exercises; medical officers were in attendance, whose duty it was to prescribe the kind and extent of the exercise; the *παιδοτρίβης* assisted and instructed the pupils, who commenced with easy exercises, from which they were gradually advanced to the more violent, till they reached the highest degree of agility and strength. Baths were attached to the gymnasia; the system most recommended was to take first a hot bath, and then to plunge immediately into cold water. Plato and Aristotle considered that no republic could be deemed perfect in which gymnasia, as part of the national establishments, were neglected. The Spartans were the most rigid in exacting for the youth a gymnastic training; even the girls were expected to be good gymnasts, and no young woman could be married till she had publicly exhibited her proficiency in various exercises. Honorable rewards and civic distinctions were publicly bestowed on the victors in the games; the rewards were styled *ἀθλα*, wherefore those who contended for them were termed *ἀθληταί*, or athletes. The exercises for the pupils in the gymnasia consisted of a sort of tumbling, and war dances; running, much recommended for both sexes; leaping, and sometimes springing from the knees having weights attached to the body; retaining the equilibrium while jumping on slippery skins full of wine, the feet being naked; wrestling for the throw, or to keep the other undermost after the throw; boxing, confined nearly exclusively to the military and athletes. The boxer either held the hands open, or he clenched brazen or stone spheres, or wore the *cæstus* or leathern band studded with metal knobs bound round his hands and wrists; there was also a mixed practice of boxing and wrestling called *παγκράτιον*. The pitching of the quoit was much practised; a variation of the quoit was found in the *δολιχέρες*, not unlike a dumb-bell, which was thrown by one to another, who caught it and then pitched it to a third, and so on; it was also adopted in extension motions, and was held in the hand with the arm extended. Javelin throwing was practised by both sexes; also throwing the bar. Riding, driving, swimming, rowing, swinging, climbing ropes, standing erect for a long time in one position, holding the breath, shouting, shooting the arrow, &c., were also taught.—

Modern gymnastics differ considerably from the exercises of the ancients. During the middle ages the knightly amusement of the tournament absorbed nearly every other sport, except the use of the quarterstaff, archery, foot racing, and wrestling, which were practised in a few places; so that gymnastics fell nearly into disuse till Basedow, in 1776, at his institution in Dessau, united bodily exercises with other instruction, which example was subsequently followed by Salzmann at his institute, and from this small commencement the practice gradually extended. In the latter part of the 18th century gymnastics were extensively introduced into Prussian schools by Guts-Muths, who wrote several works on the subject; and about 1810 the system was still more widely spread by Jahn, who may be regarded as the founder of the present *Turnvereine*. Prussia being at that time impatient under Napoleonic rule, Jahn conceived the project of bringing together the young men for the practice of gymnastic exercises, and at the same time of indoctrinating them with patriotic sentiments which might be made available to expel the French from Germany. The Prussian government favored the plan, and in the spring of 1811 a public gymnastic school or *Turnplatz* was opened at Berlin, which was quickly imitated all over the country. On Feb. 3, 1813, the king of Prussia called the citizens to arms against the French, when all those old enough to enter the military service joined the national cause, and performed signal service. Jahn himself commanded a battalion of Lützow's volunteers, and after the peace returned to his gymnastic schools. When, however, there was no longer any reason to dread French invasion, the government of Prussia, regarding the meeting of patriotic young men as a means of spreading liberal ideas, closed the gymnastic schools, and Jahn was imprisoned. In some other countries, however, the system introduced by Jahn was eminently successful, especially in England, Switzerland, Portugal, and Denmark. It was first introduced into female education under the name of callisthenics, when systematic exercises were added to hoop trundling, skipping ropes, dumb-bells, &c., already usual among the girls, and to riding, archery, and other healthy outdoor exercises among the women. The masculine sports of cricket, football, quoits, boxing, wrestling, base ball, leap-frog, foot racing, &c., have been for centuries enjoyed by the boys of England, in the play grounds attached to the schools. In 1848 the political condition of Europe enabled the turnvereins to be reorganized, and the German emigration to the United States has brought these institutions with it. The first society was formed in New York, but similar associations soon spread all over the United States. The organization, as first established, was confined to the practice of bodily exercises conducive to physical development; but it soon assumed a higher scope, without neglecting its original object;

libraries were collected, schools were established, a newspaper (*Turnzeitung*) was founded, and various arrangements were made for the diffusion of useful knowledge and for mental culture. Thus the turnvereins of the United States tread closely in the track of the academy of Athens; and when we consider the intimate connection between mind and body—how the suffering and the well-being of the one are affected by the condition of the other—too much attention can scarcely be paid to the combination of physical with mental improvement. The several local organizations of the turnverein hold annually a general meeting, by means of delegates, for the consideration of matters of common interest; they also have an annual festival, attended by representatives of the several organizations, wherein are exhibited feats of strength and agility, swimming, military manœuvres, rifle shooting, sword exercise, &c. There are, moreover, several local festivals every year in the respective districts. —There are many forms of exercise which require no special skill or practice, and which consequently may be employed with advantage by all. Excluding various games, such as base ball, cricket, and racket, and certain special exercises, as rowing, boxing, and fencing, the most available ordinary exercises are walking and horseback riding. Unless one walks at a rapid rate, little benefit is to be derived from this as an exercise. Two or three miles of walking, at the rate of four miles or more an hour, are more beneficial than a much longer walk when the movements are slow and indolent. In the former instance, the method of walking is necessarily more natural and more in accordance with the rules laid down by athletes, and the respiratory function is brought into more vigorous action. Horseback exercise, particularly the trot, is also beneficial, gives a free use of the arms and legs, strengthens the back and loins, and is generally exhilarating. Outdoor sports, such as leaping, the long and high jump, leaping with the pole, "putting the stone," throwing the hammer, running, fast and long walking, &c., are much cultivated in England and Scotland. The Caledonian games are exhilarating, produce fine and uniform muscular development, and experts in these exercises are almost always models of health and vigor. There are also many valuable methods of exercise that may be profitably employed at home, without necessarily having recourse to a regularly organized gymnasium. The best of these are the following. Swinging Indian clubs is an exercise in which there are many different movements, most of which are described in books on gymnastics. This exercise is a good one for the joints, especially the wrists, but does not produce great muscular development, or much improvement of the "wind." Exercise with light dumb-bells, five pounds or even less, making a great variety of movements, will develop and harden the muscles of the arms and shoulders,

sometimes to an extraordinary degree, particularly when combined with more severe gymnastics. This exercise may be continued with advantage almost uninterruptedly for an hour, or even longer. A great variety of movements may be performed with an arrangement of elastic bands with handles, made to imitate the pulley weights of a gymnasium. Most of the other exercises of the arms, legs, and body, called the free exercises, come under the head of callisthenics. Some of the more simple forms of gymnastic apparatus may with advantage be erected in the open air, and constitute a useful recreation for school boys. Exercises on the single or horizontal bar, and the high jump, standing or running, come under this head. A well organized gymnasium is provided with a great variety of apparatus, by which nearly every muscle in the body may be brought into play. In a complete gymnasium, an instructor is necessary at first, particularly for the young, who might otherwise, by carelessness or ignorance, produce injuries which would defeat the objects of the exercise. For the adult, exercise within proper limits in a gymnasium, particularly when taken in classes, not only develops the whole system and regulates the most important functions of the organism, but the feeling of emulation excites interest, and the exercise is valuable as a relief from mental strain. This is particularly useful for those of sedentary pursuits. The most simple gymnastic exercises are the following: the upright bars, or chest bars, which render the shoulder joints supple and expand the chest; the leg weights, pushing weights with the feet while in a sitting posture; the pulley weights, which strengthen the arms and shoulders; the rowing weights, an apparatus intended to imitate the movements in rowing; light dumb-bells, and club swinging. The more severe exercises are: the horizontal bar, upon which a great variety of feats of strength and dexterity may be performed, many of which require address that can only be acquired by long practice; horizontal and inclined ladders, which are climbed with the hands; climbing the rope; climbing the peg pole, an exercise requiring great strength in the arms, in which those with light bodies are usually most proficient; drawing the body up with one or both hands; holding the body, suspended by the hands, horizontally, with the face up or down, called the front and back horizontals, requiring great strength in nearly all the muscles; one-arm horizontals, requiring even greater strength; and holding the body extended horizontally from a perpendicular bar, the "flag," requiring considerable strength and practice. The various free exercises known as tumbling, human pyramids, &c., demand much strength, practice, agility, and confidence. The most common of these are front hand springs, "flip-flaps" or back hand springs, turning, twisting, &c., on the ground, springing from a lying posture on the ground to the erect position,

back and front somersaults from feet to feet, battoute leaping from an inclined plane, and many other feats, even more difficult, that are performed chiefly by professional gymnasts. Vaulting is a very useful and a simple exercise, which gives agility and develops strength in the arms as well as in the legs. Balancing the body upon the hands, walking on the hands, &c., give command of equilibrium. The Japanese gymnasts particularly excel in these feats. A good "hand balance" is considered very difficult to acquire, and its practice is usually begun at an early age by professional gymnasts. Some of the most useful exercises for an expert gymnast are performed in great variety upon the parallel bars. The parallel bars constitute perhaps the most useful apparatus in the gymnasium for developing the muscles of the shoulders, the chest, and the back. The single and the double trapeze are now much in vogue with gymnastic experts. The flying trapeze is not much used by amateurs, as this exercise is by no means devoid of danger, and almost all professionals acquire their skill in this at the expense of many severe falls. A great variety of difficult feats may be performed with the swinging rings. These are not so dangerous as the feats on the flying trapeze; they develop strength in the muscles of the arms, shoulders, and body, and the grip, and are entertaining and agreeable exercises. Among what are called the heavy exercises are prominent the "putting up" of heavy dumb-bells, with one or both hands, and the lifting of heavy weights with the hands or in a harness. Putting up two 100-pound dumb-bells, one in either hand, is justly considered a great feat of strength; it requires enormous power in the arms and shoulders, and particularly in the back. Putting up a single dumb-bell of 100 lbs. or more requires great strength and practice. In putting up heavy dumb-bells with one hand, the weight is carried to the shoulder with both hands, and is then raised from the shoulder with one hand until the arm and the body are straight. A single dumb-bell weighing 200 lbs. has been put up in this way with one hand, which is a Herculean feat. In exercises of this kind, the muscles should be trained gradually and carefully, otherwise severe strains are likely to occur; but heavy dumb-bells develop the muscles of the back, loins, thighs, and legs, as well as those of the arms and shoulders. Holding out weights horizontally at arm's length is a favorite heavy exercise, particularly with those who have very short and muscular arms. Lifting heavy weights with the hands, or with a harness of straps and a yoke over the shoulders, is an exercise now very much in use. In lifting with the hands alone, the lifter stands upon a platform beneath which the weight is suspended; connected with the weight are two handles of convenient shape, at a proper height; the handles are grasped, the legs are slightly bent, the back is hollowed, the arms

are straight, the shoulders are in a line with the feet, and when the lift is made the whole body is straightened. With a heavy weight, an instantaneous lift even of an inch is sufficient. The first effort is usually aided by a strong spring, which is compressed by the weight; but the lift must be made to clear the spring completely. Between 1,300 and 1,400 lbs. have been thus lifted. A heavy lift of this kind brings nearly every muscle of the body into action, but it strains particularly the grip, the muscles of the neck and the top of the shoulders, the thighs, and the small of the back. Heavy lifts are liable to produce severe strains, unless the lifting position be perfect. Lifters should proceed gradually from light to heavy weights, and should not attempt heavy lifts except under competent instruction. The so-called lift cures are undoubtedly useful, as they condense a great amount of muscular exercise into a very short time. Lifting is sometimes done with a bar between the legs, grasped with both hands; but this position is not so favorable as that with handles by the sides. In lifting with harness, the great strain is taken from the hands and transferred to the shoulders; 3,000 lbs. have been lifted in this way. Expert lifters usually lift every day a weight that they can raise with comparative ease, and make a maximum lift only once in two or three weeks. Besides the above, which comprise most of the exercises of the modern gymnasium, a number of others are sometimes practised, as evolutions on the wooden horse, exercises with wands, &c.—Callisthenics (Gr. *κάλλος*, beauty, and *σθένος*, strength) constitute a system of exercises requiring less violence of muscular action than the ordinary gymnastics. This system is considered to be better adapted to the more delicate organization of females, and is generally confined in its application to that sex. Its purpose is to give equal development to all the muscles, and thus produce that harmony of action on which depends not only health, but regularity of proportion and grace of movement. Callisthenics may be practised mediately or immediately, with or without apparatus. All the apparatus required, when used, is a strong chair, a short roller fixed in sockets near the top of an open doorway, a light wooden staff, about 4½ ft. in length and half an inch in diameter, a pair of light dumb-bells, a hair mattress, a pair of square weights, and two parallel bars. The exercises with these are simple, and can be readily learned in a lesson or two from a teacher, or from any of the numerous manuals published on the subject. In the chair exercise, the pupil plants the feet at a certain distance from the chair, and then leans forward on tiptoe, and rests the hands upon the back of the chair. The exercise consists in moving the body slowly backward and forward between the two fixed points of the toes on the floor and the hands on the back of the chair. This simple manœuvre is admirably adapted for the expansion of the chest and the develop-

ment of all the muscles of the body. In the roller exercise, the pupil is suspended by the hands a few inches above the floor, and swings in this position, or moves the grasp alternately from side to side. A great number of graceful and strengthening movements may be made with the staff. One of the best is to hold it in both hands, and pass it successively over the head to the right and left, bringing it down each time below the middle of the person, in front or behind. The dumb-bells, being grasped by the hands, are to be moved forward and backward horizontally from the chest, or, with the arms below the hips, to be moved circularly about the body, until they meet before and behind. The exercise on the mattress consists merely in raising the person from a horizontal to a sitting posture, with the arms and legs extended and not used to aid in the movement. The square weights may be used in most cases like the dumb-bells. They have, however, the peculiar advantage of a form which allows of their being placed upon the head. This is one of the best possible means of giving uprightness to the figure, as in thus balancing a weight the spine is necessarily brought by the muscles of the back into a straight position. The negro women of the south, who are in the habit of carrying heavy burdens on their head, are remarkable for erectness of the body. The parallel bars are two poles fastened by their ends to the floor and the ceiling, at a proper distance apart, and of a thickness to be readily grasped by the hands of the pupil, which being done, the body is moved backward and forward between them. Every necessary exercise, however, can be practised without the use of apparatus of any kind, and the system of callisthenics founded on this basis is probably best for general adoption, as it is less liable to abuse from the intemperate zeal of the pupil, and more calculated to preserve the beautiful, which few women will be persuaded to exchange for any acquisition of strength. When apparatus is used, the effort is more violent, and the muscles may become so prominently developed as to cause the absorption of the soft cellular tissue which cushions the human frame, and which, by its abundance in the female, gives roundness and fulness to the form. The constant handling of the hard material of the apparatus, also, is apt to produce a disproportionate enlargement of the hand and harden its texture. The callisthenic exercises without apparatus consist in regular and systematic movements of the entire body. The head and the trunk are moved up and down, forward and backward, to the right and left; the arms and legs, and hands and feet, are also exercised so that every voluntary muscle is brought into action. The object being to give an equal muscular development to the whole frame, the exercises are so arranged that all parts of the body are successively brought into action. None of the movements are complicated, and

they are in fact no more than those usual in the ordinary exercise of the limbs. Callisthenics, however, by reducing these to a system, insures an equal and regular action of the muscles, while the occupations or amusements of females are apt to effect the reverse. It is essential that all these exercises should be practised, if indoors, in well ventilated halls or apartments. The practical utility of all gymnastics is frequently diminished by monotony, the pupil becoming wearied with the uniformity of the movements. Without the discipline of a teacher, it is difficult to secure a long persistence in their use. It is well therefore to vary them, or to associate with them as much as possible the idea of amusement. In fact, there is no better callisthenic apparatus than many of the ordinary playthings, such as the battledore and shuttlecock, the cup and ball, and the "graces." In modern callisthenics, regulating the movements to the time of music is much employed, and is useful, as it relieves their monotony. Ling, the Swedish writer on gymnastics and callisthenics, has written enthusiastically upon the advantage of systematic muscular exercise in the cure of disease. Numerous ailments to which females are peculiarly liable are due to the neglect of proper physical training, and may doubtless be relieved in many instances by the proper application of callisthenics. Most of these female disorders may be justly attributed to the weakness of the abdominal muscles, and a proper strengthening of these by exercise, would no doubt remove the cause. It is evident that callisthenics, so called, are almost identical with the lighter forms of regular gymnastic exercise, and are adapted to the male as well as to the female. Exhibitions of large classes, the movements being simultaneous and performed to the time of appropriate music, are often quite graceful and entertaining.—Systematic gymnastic or callisthenic exercises are rarely if ever useful before the age of 12 or 14 years. Professional gymnasts, many of whom begin their training at a very early age, are seldom well formed men, frequently presenting extraordinary development of certain muscles at the expense of others, which amounts almost to deformity. Before the age of 12 the games and pastimes of childhood generally afford sufficient exercise; at that age, however, the lighter gymnastics or callisthenics, under competent instruction, may be the first step in the full development of a muscular system, which moderate exercise will preserve in a robust condition throughout adult life. After the age of 35 even practised gymnasts should be careful in making extraordinary muscular efforts. At that time the ligaments are comparatively stiff, and strains of the joints are apt to become troublesome and persistent. By persons of sedentary habits, gymnastic exercise is to be employed to secure health, and it is not desirable to carry training to the extent of reducing the adipose tissue to the minimum. A

fair development of fat is normal in the adult, and the system is apt to become exhausted if kept too long at a high standard of muscular development. Persons who have an unusual tendency to fat should combine with other exercise running, jumping on the spring-board, and movements which shake the body. These favor the absorption of unnecessary adipose tissue, especially in the covering of the abdominal organs, allow the diaphragm to play more freely, and give respiratory power or "wind." It is a good plan for the adult to use moderate exercise, which develops the muscular system generally, and to make one vigorous effort each day, such as lifting a heavy weight or raising a large dumb-bell. This gives nervous power, and enables one to easily put forth nearly all his strength in a single powerful effort, when this is required. It is not necessary for an adult, exercising simply for health, to cultivate excessive hardness of muscle; and indeed the greatest strength is often found in muscles that are comparatively soft. One hour's honest exercise, followed by ablution, will usually suffice for the brain-worker; and this should produce prompt reaction, without a sense of exhaustion. Persons who take this amount of judicious exercise are often more powerful and have more endurance than the hard-worked laborer. There is no doubt that judicious and habitual exercise favors the elimination of effete matters from the organism, particularly by the lungs, skin, and kidneys, increases the activity of the nutrition of the muscular system, rendering the food more relishing, more easily digested, and better assimilated, and develops what is known as nerve power. When it is remembered that the muscles constitute the great bulk of the organism, it is evident that perfect health can only exist when they are properly developed. Active nutrition of the muscles, also, is unfavorable to the deposition of morbid matters, such as are found in tuberculous, cancerous, or scrofulous constitutions; and when exercise is combined with amusement and mental relaxation, the system is in the best condition to derive its full benefit.—Ancient gymnastics are treated of in a few works: Plato, "Politics," book iii., and "Laws," book viii.; Galen, "On Preserving Health;" and Hieronymus Mercurialis, *De Arte Gymnastica*, book vi. (Venice, 1587). On modern gymnastics there are numerous treatises. Many German physicians have labored to raise gymnastics to the importance of a science, especially Dr. Schreber of Leipsic; see his *Kinesiatrik* (Leipsic, 1852) and *Aerztliche Zimmergymnastik* (5th ed., 1858). The more recent works published in the United States and England are the following: Arthur and Charles Nahl, "Instructions in Gymnastics" (San Francisco, 1863); Watson, "Callisthenics and Gymnastics" (New York and Philadelphia, 1864); William Wood, "Manual of Physical Exercises" (New York, 1867);

Ravenstein and Hulley, "Gymnastics and Athletics" (London, 1867).

**GYMNOSOPHISTS** (Gr. γυμνός, naked, and σοφιστής, a philosopher), a sect of ancient Indian philosophers, so called by the Greeks because they went naked, or almost naked. They were also called βραχμναί, Brahmans. They dwelt in the woods, and lived on the wild products of the earth. They were remarkable for their contempt of death, and practised suicide by burning. In this way Calanus sacrificed himself at Babylon, in the presence of Alexander the Great, and Xarimarus at Athens, in that of Augustus. The gymnosophists had a great reputation for wisdom and learning. Their most prominent tenet was the doctrine of the immortality and transmigration of the soul.

**GYMNOTUS.** See ELECTRIC FISHES.

**GÝNGYÖS,** a town of Hungary, in the county of Heves, 44 m. N. E. of Pesth; pop. in 1869, 15,830. It is situated at the foot of the Mátra range, contains a fine castle in which is an interesting collection of armor, four Catholic churches, a Franciscan monastery, town house, and gymnasium. It has extensive manufactories of woollen stuffs, several tanneries and mills, an active trade in cattle and cheese, a weekly market, and numerous well frequented fairs. Near it are silver and copper mines.

**GYPSIES, Gipsies, or Gipseys** (a corruption of the word Egyptians), a vagabond people now found in most parts of the world. The names given to them by other nations are: Zingari in Italy, Gitanos in Spain, Zigeuner in Germany, Czigányok in Hungary, Tzigani in Slavic countries, Tchinganeh in Turkey, Bohémiens in France (as they pretended to come from Bohemia), &c. They are also nicknamed Mattois, Gueux, Cagoux, and their language Blesquin in France; Zieh-Gauner (wandering rogues) in Germany, heathens in Holland, Tartars in Sweden, &c. They call themselves Kale or Mellele (the black), Mellelitchel (black people), Sinte or Sinte (probably from the Sanskrit *Saindhavas*, people of the Indies), but more commonly by some word signifying "people" in the various gypsy dialects, as Manush, Rom, feminine Romni. As they are ignorant of their origin, and as history has failed to record their migrations, there are very many opinions on the subject. Hasse and Schirak attempted to connect them with the *Σκυθῶναι* of Herodotus, north of the lower Ister (Danube), reported to be of Median origin. Büttner, Rüdiger, Bacmeister, Pallas, and Grellmann consider them to have come from India, whence they were driven by the ravages of Tamerlane (1398), and where they belonged to the Soodra caste, or to the Pariahs. Hiob Ludolf (*Commentarius ad Historiam Æthiopicam*, 1691) gave a list of words supposed to be Egyptian, but which are rather Slavic. There are many roving tribes in India and Persia which resemble the gypsies. In northern Persia they are known as Karatchi, and in

Kermanshah and Kurdistan as Kauli and Susmani. The Zingarro or Chungur of the Punjab are also a wandering race. Vigne holds that modern gypsies are descendants of Cashmere Hindoos who fled from persecution toward the end of the 14th century. Arab Shah, who lived at Samarcand in 1422, says in his "Life of Timour" that the gypsies were probably descendants of Buddhists who emigrated about 300 B. C., when persecuted by Nara. In a paraphrase of the book of Genesis, written by an Austrian monk in 1122, similar vagrants were noticed as being Ishmaelites; but organized bands of gypsies first appeared in the Danubian provinces in 1417. They numbered about 14,000 in Italy as early as 1422. On Aug. 17, 1427, arrived at Paris a band of 120 strangers, claiming to be Christians of Lower Egypt who had been expelled

Bohemian Gypsies.

by the Saracens. They said they had last come from Bohemia. They professed the gifts of fortune-telling and palmistry, and were great thieves. They were expelled from Paris, but continued to wander in France, and other bands succeeded them. They appeared in Spain in 1447, in England about 1506, and in Sweden in 1514. Wherever they came they practised the arts of thieving and deception. Severe laws were passed against them, but these measures, not being simultaneous in the various states, failed of their effect. Spain exiled them in 1492, and about a century later renewed the decree of banishment. In England, Henry VIII. issued in 1530 a proclamation, subsequently renewed by Elizabeth, which made their stay in England for over a month a capital felony. The Scottish kings pursued a different policy, and seem to have

given them a sort of protection. Italy, Denmark, Sweden, the Netherlands, and Germany took measures against them. In the first half of the 16th century they probably received an accession of numbers from Egypt, for in 1517 a revolt against the conquest of Sultan Selim took place under one Zinganeus, whose followers, being banished, took to wandering throughout the world in small companies. The sovereigns of Germany made efforts to reclaim and settle the gypsies. Maria Theresa in 1768 ordered that the numerous bands throughout her dominions should be gathered in settled habitations, practise some trade, have their children educated, and be called *Neubauern*, new peasants. As they failed to obey, severer measures were enforced by Joseph II. in 1782, and at present the gypsies of Hungary, Transylvania, and Roumania, together about 250,000, lead a more settled life than their brethren anywhere else. In Transylvania they are under the rule of a waywode of their own race, elected by themselves. They are likewise numerous in the southern provinces of Russia and in Turkey generally. Spain contains about 40,000, some of whom follow a mixed occupation, as keepers of wine shops and horse dealers. A considerable number are in Norway; in France there are few or none; and in England their numbers have decreased to about 10,000. Estimates of the total number of gypsies in Europe are variously given from 500,000 to 700,000. The laws against them have in most countries fallen into desuetude, they having to contend with a stronger force than legal prohibitions in the increase of intelligence among the rural population, who were formerly their patrons and victims. In England the oppressive statutes against them were repealed in 1783, 1820, and 1856.—The gypsy physiognomy is Asiatic in type, with tawny complexion, quick black eyes, black hair, high cheek bones, slightly projecting lower jaw, narrow mouth with fine white teeth, which, with their lithe and agile figure, causes some of their young women to be considered beauties. Their habits are, however, so squalid and depraved as to cause them before they are past middle age to fall into decrepitude. The gypsies have few redeeming characteristics. They are treacherous, cowardly, revengeful, and cruel. They have little or no religious belief, and no words in their language to signify God, the soul, or immortality. Velasquez says, "The gypsies' church was built of lard, and the dogs ate it." Marriage is a temporary form with them, and the limits of consanguinity are not respected. They pretend that their skill in palmistry is the lore of the Egyptians. Their industry reaches no higher than the tinkering of hardware and turning small articles in wood, with occasionally some assistance reluctantly given in farm labor. In Transylvania they do a little in washing gold. They frequently act as musicians, as they have a remarkable quickness in acquiring tunes by

ear. Some of them, as Keeskeméti, Kálozdy, and Bunkó, have been celebrated violinists. The young persons of both sexes are fond of dancing, and exhibit their skill for money, especially in Spain. The men wear no distinguishing dress from other similar vagabonds, but the women indulge their passion for gay colors and trinkets. In England the recognized gypsy woman's apparel is a red cloak with a hood, and a handkerchief tied over the head. Their huts are mere kennels of earth and boughs. It has been a question whether a band of genuine gypsies has ever been in America; but many English authorities maintain that the decrease of their number in the British isles is in a great measure due to their having emigrated to the United States.—The language of the gypsies, though everywhere preserving forms of an unmistakably Indian origin, differs greatly in the various countries in which it is spoken. The best known are the English, German, Hungarian, and Spanish gypsy dialects. We shall confine ourselves to the English dialect, and follow the statements made in regard to it by Bath C. Smart before the English philological society in London. The English gypsies generally use the English article, and but seldom their own forms, *o* for the masculine and *y* for the feminine. Nouns generally terminate in a consonant, or else in *o* when masculine, and in *i* or *y* when feminine. The genitive is formed by adding *esko* or *esto*; the plural by *yor* or *or*, and sometimes with an additional *s*, taken from English; as *skammin*, a chair, *skamminyors*, chairs. Adjectives have invariably a final *o* or *y*, added even to English words. The comparative is formed by adding *dair* or *dairo* when there are no special forms, like *coosko*, good, *fetterdairo*, better. There seems to be no superlative termination. The pronouns are in many cases preserved in their original form, as *yor*, he; *lesty*, his; *yoi*, she; *latty*, her. Instead of "I," they use "me," but for "of me" they return to their own *mandy*. The numerals are: *yek*, one; *dooeey*, two; *tring*, three; *stor*, four; *panch*, five; *shov*, six; *afta*, seven; *oitoo*, eight; *enneah*, nine; and *desh*, ten. *Afta*, *oitoo*, and *enneah* are, however, of rare occurrence. Verbs are generally inflected as in English, but *av* is sometimes added as a sign of the first, and *ella* or *l* of the third person singular. Prepositions are: *agal*, before; *adrey*, within; *aprey*, upon; *taley*, down; *paudel*, over. The ease with which the gypsies introduce foreign words into their own speech will be seen from the following proverbs given by Charles G. Leland in his book "The English Gypsies and their Language" (London, 1873):

*A cloudy sala often purabens to a fino divvus.*  
A cloudy morning often changes to a fine day.

*It's sim to a choomer, kushti for kek till it's*  
It's like a kiss, good for nothing until it is

*pordered atween divi.*  
divided between two.

—Works on the gypsies and their dialects are: Valentz's "Description of the East Indies" (Amsterdam, 1724-'6); Peyssonel, *Sur les peuples barbares qui ont habité sur les bords du Danube* (1765); Pray, *Annales Regum Hungariæ* (5 vols. fol., Vienna, 1764-'70); Grellmann, *Historische Versuche über die Zigeuner* (Göttingen, 2d ed., 1787); Molnár, *Specimen Lingue Cingariæ* (Debreczin, 1798); Gardiner, "Essays, Literary, Political," &c. (Edinburgh, 1803); Hasse, *Zigeuner im Herodot* (Königsberg, 1803); Bischoff, *Deutsch-Zigeunerisches Wörterbuch* (Ilmenau, 1827); John Staples Harriot, in the "Transactions of the Asiatic Society" for 1831; Cogalniceanu, *Essai sur l'histoire, les mœurs et la langue des Cigains* (Berlin, 1837); Predari, *Origine e vicende dei Zingari* (Milan, 1841); George Borrow, "The Zincali, or an Account of the Gypsies of Spain" (2 vols., London, 1841); Von Heister, *Ethnographie und geschichtliche Notizen über die Zigeuner* (Königsberg, 1842); Pott, *Die Zigeuner in Europa und Asien* (Halle, 1844-'5); Bataillard, *De l'apparition et de la dispersion des Bohémiens en Europe* (in the 5th vol. of the *Bibliothèque de l'école de Chartres*, 1844); Böhtlingk, *Die Sprache der Zigeuner in Russland* (St. Petersburg, 1852); Jimenez, *Vocabulario del dialecto gitano* (Madrid, 1854); Liebig, *Die Zigeuner in ihrem Wesen und in ihrer Sprache* (Leipzig, 1863); Ascoli, *Ziguenisches* (Halle, 1865); Simson, "History of the Gypsies" (London, 1865); Kivasnikoff, "Collection of Songs of the Russian Gypsies," in Russian (Moscow, 1869); Borrow, "Lavo-Lil: Word Book of the Romany or English Gypsy Language" (London, 1874); and numerous articles in the publications of philological societies.

**GYPSUM**, a common mineral, frequently crystallized, oftener amorphous, and sometimes forming rock masses. Its crystallization is monoclinic; hardness, 1.5 to 2; specific gravity, 2.2 to 2.4; transparent or translucent, vitreous; on cleavage, pearly or silky; colorless and snow-white, but often red, yellow, or brown from enclosed coloring matters. Its transparent variety, called selenite, sometimes occurs in large plates, which have been used for windows. It also frequently occurs in aggregated needle-like crystals, and is then called fibrous gypsum. In its amorphous condition, when compact and translucent, it is named alabaster. More commonly it is white, opaque, and soft, and is then called snowy gypsum. Its chemical composition is expressed by the formula  $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ ; i. e., it is a hydrated sulphate of lime. Gypsum occurs in nearly all geological formations and countries. In clay and shale it is frequently found in beautifully defined detached crystals, apparently derived from the action of sulphuric acid, liberated by the decomposition of iron pyrites on carbonate of lime. It is also formed where sulphuric acid is generated or discharged from volcanic or other subterranean sources and comes in contact with calcareous matter,
